The kk style of this command can only be invoked if LAMMPS was built with the KOKKOS package. See the Build package doc page for more info.

The omp style of this command can only be invoked if LAMMPS was built with the USER-OMP package. See the Build package doc page for more info.

17.87.5 Related commands

suffix, -pk command-line switch

17.87.6 Default

For the GPU package, the default is Ngpu = 1 and the option defaults are neigh = yes, newton = off, binsize = 0.0, split = 1.0, gpuID = 0 to Ngpu-1, tpa = 1, and device = not used. These settings are made automatically if the “-sf gpu” command-line switch is used. If it is not used, you must invoke the package gpu command in your input script or via the “-pk gpu” command-line switch.

For the USER-INTEL package, the default is Nphi = 1 and the option defaults are omp = 0, mode = mixed, lrt = no, balance = -1, tpc = 4, tptask = 240. The default ghost option is determined by the pair style being used. This value is output to the screen in the offload report at the end of each run. Note that all of these settings, except “omp” and “mode”, are ignored if LAMMPS was not built with Xeon Phi co-processor support. These settings are made automatically if the “-sf intel” command-line switch is used. If it is not used, you must invoke the package intel command in your input script or via the “-pk intel” command-line switch.

For the KOKKOS package, the option defaults for GPUs are neigh = full, neigh/qeq = full, newton = off, binsize = 2x LAMMPS default value, comm = device, cuda/aware = on. When LAMMPS can safely detect that CUDA-aware MPI is not available, the default value of cuda/aware becomes “off”. For CPUs or Xeon Phis, the option defaults are neigh = half, neigh/qeq = half, newton = on, binsize = 0.0, and comm = no. The option neigh/thread = on when there are 16K atoms or less on an MPI rank, otherwise it is “off”. These settings are made automatically by the required “-k on” command-line switch. You can change them by using the package kokkos command in your input script or via the -pk kokkos command-line switch.

For the OMP package, the default is Nthreads = 0 and the option defaults are neigh = yes. These settings are made automatically if the “-sf omp” command-line switch is used. If it is not used, you must invoke the package omp command in your input script or via the “-pk omp” command-line switch.
17.88 pair_coeff command

17.88.1 Syntax

```
pair_coeff I J args
```

- I,J = atom types (see asterisk form below)
- args = coefficients for one or more pairs of atom types

17.88.2 Examples

```
pair_coeff 1 2 1.0 1.0 2.5
pair_coeff 2 * 1.0 1.0
pair_coeff 3* 1*2 1.0 1.0 2.5
pair_coeff * * 1.0 1.0
pair_coeff * * nialhjea 1 1 2
pair_coeff * 3 morse.table ENTRY1
pair_coeff 1 2 lj/cut 1.0 1.0 2.5 (for pair_style hybrid)
```

17.88.3 Description

Specify the pairwise force field coefficients for one or more pairs of atom types. The number and meaning of the coefficients depends on the pair style. Pair coefficients can also be set in the data file read by the `read_data` command or in a restart file.

I and J can be specified in one of two ways. Explicit numeric values can be used for each, as in the first example above. I <= J is required. LAMMPS sets the coefficients for the symmetric J,I interaction to the same values.

A wildcard asterisk can be used in place of or in conjunction with the I,J arguments to set the coefficients for multiple pairs of atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that only type pairs with I <= J are considered; if asterisks imply type pairs where J < I, they are ignored.

Note that a pair_coeff command can override a previous setting for the same I,J pair. For example, these commands set the coeffs for all I,J pairs, then overwrite the coeffs for just the I,J = 2,3 pair:

```
pair_coeff * * 1.0 1.0 2.5
pair_coeff 2 3 2.0 1.0 1.12
```

A line in a data file that specifies pair coefficients uses the exact same format as the arguments of the pair_coeff command in an input script, with the exception of the I,J type arguments. In each line of the “Pair Coeffs” section of a data file, only a single type I is specified, which sets the coefficients for type I interacting with type I. This is because the section has exactly N lines, where N = the number of atom types. For this reason, the wild-card asterisk should also not be used as part of the I argument. Thus in a data file, the line corresponding to the first example above would be listed as

```
2 1.0 1.0 2.5
```

For many potentials, if coefficients for type pairs with I != J are not set explicitly by a pair_coeff command, the values are inferred from the I,I and J,J settings by mixing rules; see the `pair_modify` command for a discussion. Details on this option as it pertains to individual potentials are described on the doc page for the potential.
Many pair styles, typically for many-body potentials, use tabulated potential files as input, when specifying the pair_coeff command. Potential files provided with LAMMPS are in the potentials directory of the distribution. For some potentials, such as EAM, other archives of suitable files can be found on the Web. They can be used with LAMMPS as long as they are in the format LAMMPS expects, as discussed on the individual doc pages. The first line of potential files may contain metadata with upper case tags followed their value. These may be parsed and used by LAMMPS. Currently supported are the “DATE:” tag and the UNITS: tag. For pair styles that have been programmed to support the metadata, the value of the “DATE:” tag is printed to the screen and logfile so that the version of a potential file can be later identified. The UNITS: tag indicates the units setting required for this particular potential file. If the potential file was created for a different sets of units, LAMMPS will terminate with an error. If the potential file does not contain the tag, no check will be made and it is the responsibility of the user to determine that the unit style is correct.

In some select cases and for specific combinations of unit styles, LAMMPS is capable of automatically converting potential parameters from a file. In those cases, a warning message signaling that an automatic conversion has happened is printed to the screen.

When a pair_coeff command using a potential file is specified, LAMMPS looks for the potential file in 2 places. First it looks in the location specified. E.g. if the file is specified as “niu3.eam”, it is looked for in the current working directory. If it is specified as “../potentials/niu3.eam”, then it is looked for in the potentials directory, assuming it is a sister directory of the current working directory. If the file is not found, it is then looked for in one of the directories specified by the LAMMPS_POTENTIALS environment variable. Thus if this is set to the potentials directory in the LAMMPS distribution, then you can use those files from anywhere on your system, without copying them into your working directory. Environment variables are set in different ways for different shells. Here are example settings for csh, tcsh:

```
% setenv LAMMPS_POTENTIALS /path/to/lammps/potentials
```

bash:

```
% export LAMMPS_POTENTIALS=/path/to/lammps/potentials
```

Windows:

```
% set LAMMPS_POTENTIALS="C:\Path to LAMMPS\Potentials"
```

The LAMMPS_POTENTIALS environment variable may contain paths to multiple folders, if they are separated by “;” on Windows and “:” on all other operating systems, just like the PATH and similar environment variables.

The alphabetic list of pair styles defined in LAMMPS is given on the pair_style doc page. They are also listed in more compact form on the Commands pair doc page.

Click on the style to display the formula it computes and its coefficients as specified by the associated pair_coeff command.

17.88.4 Restrictions

This command must come after the simulation box is defined by a read_data, read_restart, or create_box command.

```
pair_modify shift yes mix geometric
pair_modify tail yes
pair_modify table 12
pair_modify pair lj/cut compute no
pair_modify pair tersoff compute/tally no
pair_modify pair lj/cut/coul/long 1 special lj/coul 0.0 0.0 0.0
pair_modify pair lj/cut/coul/long special lj 0.0 0.0 0.5 special coul 0.0 0.0 0.
```
17.89.3 Description

Modify the parameters of the currently defined pair style. If the pair style is hybrid or hybrid/overlay, then the specified parameters are by default modified for all the hybrid sub-styles.

Note: The behavior for hybrid pair styles can be changed by using the pair keyword, which allows selection of a specific sub-style to apply all remaining keywords to. The special and compute/tally keywords can only be used in conjunction with the pair keyword. See further details about these 3 keywords below.

The mix keyword affects pair coefficients for interactions between atoms of type I and J, when I != J and the coefficients are not explicitly set in the input script. Note that coefficients for I = J must be set explicitly, either in the input script via the pair_coeff command or in the “Pair Coeffs” section of the data file. For some pair styles it is not necessary to specify coefficients when I != J, since a “mixing” rule will create them from the I,I and J,J settings. The pair_modify mix value determines what formulas are used to compute the mixed coefficients. In each case, the cutoff distance is mixed the same way as sigma.

Note that not all pair styles support mixing and some mix options are not available for certain pair styles. Also, there are additional restrictions when using pair style hybrid or hybrid/overlay. See the doc page for individual pair styles for those restrictions. Note also that the pair_coeff command also can be used to directly set coefficients for a specific I != J pairing, in which case no mixing is performed.

- mix geometric

\[
\begin{align*}
\epsilon_{ij} &= \sqrt{\epsilon_i \epsilon_j} \\
\sigma_{ij} &= \sqrt{\sigma_i \sigma_j}
\end{align*}
\]

- mix arithmetic

\[
\begin{align*}
\epsilon_{ij} &= \sqrt{\epsilon_i \epsilon_j} \\
\sigma_{ij} &= \frac{1}{2}(\sigma_i + \sigma_j)
\end{align*}
\]

- mix sixthpower

\[
\begin{align*}
\epsilon_{ij} &= \frac{2}{\sigma_i^6 + \sigma_j^6} \sqrt[3]{\epsilon_i \epsilon_j} \sigma_i^3 \sigma_j^3 \\
\sigma_{ij} &= \left(\frac{1}{2}(\sigma_i^6 + \sigma_j^6)\right)^\frac{1}{6}
\end{align*}
\]

The shift keyword determines whether a Lennard-Jones potential is shifted at its cutoff to 0.0. If so, this adds an energy term to each pairwise interaction which will be included in the thermodynamic output, but does not affect pair forces or atom trajectories. See the doc page for individual pair styles to see which ones support this option.

The table and table/disp keywords apply to pair styles with a long-range Coulombic term or long-range dispersion term respectively; see the doc page for individual styles to see which potentials support these options. If N is non-zero, a table of length $2^N$ is pre-computed for forces and energies, which can shrink their computational cost by up to a factor of 2. The table is indexed via a bit-mapping technique (Wolff) and a linear interpolation is performed between adjacent table values. In our experiments with different table styles (lookup, linear, spline), this method typically gave the best performance in terms of speed and accuracy.

The choice of table length is a tradeoff in accuracy versus speed. A larger N yields more accurate force computations, but requires more memory which can slow down the computation due to cache misses. A reasonable value of N is between 8 and 16. The default value of 12 (table of length 4096) gives approximately the same accuracy as the no-table (N = 0) option. For N = 0, forces and energies are computed directly, using a polynomial fit for the needed erfc()
function evaluation, which is what earlier versions of LAMMPS did. Values greater than 16 typically slow down the simulation and will not improve accuracy; values from 1 to 8 give unreliable results.

The `tabinner` and `tabinner/disp` keywords set an inner cutoff above which the pairwise computation is done by table lookup (if tables are invoked), for the corresponding Coulombic and dispersion tables discussed with the `table` and `table/disp` keywords. The smaller the cutoff is set, the less accurate the table becomes (for a given number of table values), which can require use of larger tables. The default cutoff value is sqrt(2.0) distance units which means nearly all pairwise interactions are computed via table lookup for simulations with “real” units, but some close pairs may be computed directly (non-table) for simulations with “lj” units.

When the `tail` keyword is set to `yes`, certain pair styles will add a long-range VanderWaals tail “correction” to the energy and pressure. These corrections are bookkeeping terms which do not affect dynamics, unless a constant-pressure simulation is being performed. See the doc page for individual styles to see which support this option. These corrections are included in the calculation and printing of thermodynamic quantities (see the `thermo_style` command). Their effect will also be included in constant NPT or NPH simulations where the pressure influences the simulation box dimensions (e.g. the `fix npt` and `fix nph` commands). The formulas used for the long-range corrections come from equation 5 of (Sun).

**Note:** The tail correction terms are computed at the beginning of each run, using the current atom counts of each atom type. If atoms are deleted (or lost) or created during a simulation, e.g. via the `fix gcmc` command, the correction factors are not re-computed. If you expect the counts to change dramatically, you can break a run into a series of shorter runs so that the correction factors are re-computed more frequently.

Several additional assumptions are inherent in using tail corrections, including the following:

- The simulated system is a 3d bulk homogeneous liquid. This option should not be used for systems that are non-liquid, 2d, have a slab geometry (only 2d periodic), or inhomogeneous.
- \( G(r) \), the radial distribution function (rdf), is unity beyond the cutoff, so a fairly large cutoff should be used (i.e. 2.5 sigma for an LJ fluid), and it is probably a good idea to verify this assumption by checking the rdf. The rdf is not exactly unity beyond the cutoff for each pair of interaction types, so the tail correction is necessarily an approximation.

The tail corrections are computed at the beginning of each simulation run. If the number of atoms changes during the run, e.g. due to atoms leaving the simulation domain, or use of the `fix gcmc` command, then the corrections are not updated to reflect the changed atom count. If this is a large effect in your simulation, you should break the long run into several short runs, so that the correction factors are re-computed multiple times.

- Thermophysical properties obtained from calculations with this option enabled will not be thermodynamically consistent with the truncated force-field that was used. In other words, atoms do not feel any LJ pair interactions beyond the cutoff, but the energy and pressure reported by the simulation include an estimated contribution from those interactions.

The `compute` keyword allows pairwise computations to be turned off, even though a `pair_style` is defined. This is not useful for running a real simulation, but can be useful for debugging purposes or for performing a `rerun` simulation, when you only wish to compute partial forces that do not include the pairwise contribution.

Two examples are as follows. First, this option allows you to perform a simulation with `pair_style hybrid` with only a subset of the hybrid sub-styles enabled. Second, this option allows you to perform a simulation with only long-range interactions but no short-range pairwise interactions. Doing this by simply not defining a pair style will not work, because the `kspace_style` command requires a Kspace-compatible pair style be defined.

The `nofdotr` keyword allows to disable an optimization that computes the global stress tensor from the total forces and atom positions rather than from summing forces between individual pairs of atoms.

The `pair` keyword can only be used with the `hybrid` and `hybrid/overlay` pair styles. If used, it must appear first in the list of keywords.
Its meaning is that all the following parameters will only be modified for the specified sub-style. If the sub-style is defined multiple times, then an additional numeric argument N must also be specified, which is a number from 1 to M where M is the number of times the sub-style was listed in the pair_style hybrid command. The extra number indicates which instance of the sub-style the remaining keywords will be applied to.

The special and compute/tally keywords can only be used in conjunction with the pair keyword and they must directly follow it. I.e. any other keyword, must appear after pair, special, and compute/tally.

The special keyword overrides the global special_bonds 1-2, 1-3, 1-4 exclusion settings (weights) for the sub-style selected by the pair keyword.

Similar to the special_bonds command, it takes 4 arguments. The which argument can be lj to change only the non-Coulomb weights (e.g. Lennard-Jones or Buckingham), coul to change only the Coulombic settings, or lj/coul to change both to the same values. The wt1,wt2,wt3 values are numeric weights from 0.0 to 1.0 inclusive, for the 1-2, 1-3, and 1-4 bond topology neighbors, respectively. The special keyword can be used multiple times, e.g. to set the lj and coul settings to different values.

Note: The special keyword is not compatible with pair styles from the GPU or the USER-INTEL package and attempting to use it will cause an error.

Note: Weights of exactly 0.0 or 1.0 in the special_bonds command have implications on the neighbor list construction, which means that they cannot be overridden by using the special keyword. One workaround for this restriction is to use the special_bonds command with weights like 1.0e-10 or 0.999999999 instead of 0.0 or 1.0, respectively, which enables to reset each them to any value between 0.0 and 1.0 inclusively. Otherwise you can set all global weights to an arbitrary number between 0.0 or 1.0, like 0.5, and then you have to override all special settings for all sub-styles which use the 1-2, 1-3, and 1-4 exclusion weights in their force/energy computation.

The compute/tally keyword disables or enables registering compute */tally computes for the sub-style specified by the pair keyword. Use no to disable, or yes to enable.

Note: The “pair_modify pair compute/tally” command must be issued before the corresponding compute style is defined.

17.89.4 Restrictions

You cannot use shift yes with tail yes, since those are conflicting options. You cannot use tail yes with 2d simulations. You cannot use special with pair styles from the GPU or USER-INTEL package.

17.89.5 Related commands

pair_style, pair_style hybrid, pair_coeff, thermo_style, compute */tally
17.89.6 Default

The option defaults are mix = geometric, shift = no, table = 12, tabinner = sqrt(2.0), tail = no, and compute = yes.
Note that some pair styles perform mixing, but only a certain style of mixing. See the doc pages for individual pair styles for details.

17.90 pair_style command

17.90.1 Syntax

pair_style style args

• style = one of the styles from the list below
• args = arguments used by a particular style

17.90.2 Examples

pair_style lj/cut 2.5
pair_style eam/alloy
pair_style hybrid lj/charmm/coul/long 10.0 eam
pair_style table linear 1000
pair_style none

17.90.3 Description

Set the formula(s) LAMMPS uses to compute pairwise interactions. In LAMMPS, pair potentials are defined between pairs of atoms that are within a cutoff distance and the set of active interactions typically changes over time. See the bond_style command to define potentials between pairs of bonded atoms, which typically remain in place for the duration of a simulation.

In LAMMPS, pairwise force fields encompass a variety of interactions, some of which include many-body effects, e.g. EAM, Stillinger-Weber, Tersoff, REBO potentials. They are still classified as “pairwise” potentials because the set of interacting atoms changes with time (unlike molecular bonds) and thus a neighbor list is used to find nearby interacting atoms.

Hybrid models where specified pairs of atom types interact via different pair potentials can be setup using the hybrid pair style.

The coefficients associated with a pair style are typically set for each pair of atom types, and are specified by the pair_coeff command or read from a file by the read_data or read_restart commands.

The pair_modify command sets options for mixing of type I-J interaction coefficients and adding energy offsets or tail corrections to Lennard-Jones potentials. Details on these options as they pertain to individual potentials are described on the doc page for the potential. Likewise, info on whether the potential information is stored in a restart file is listed on the potential doc page.
In the formulas listed for each pair style, $E$ is the energy of a pairwise interaction between two atoms separated by a distance $r$. The force between the atoms is the negative derivative of this expression.

If the pair_style command has a cutoff argument, it sets global cutoffs for all pairs of atom types. The distance(s) can be smaller or larger than the dimensions of the simulation box.

Typically, the global cutoff value can be overridden for a specific pair of atom types by the pair_coeff command. The pair style settings (including global cutoffs) can be changed by a subsequent pair_style command using the same style. This will reset the cutoffs for all atom type pairs, including those previously set explicitly by a pair_coeff command. The exceptions to this are that pair_style table and hybrid settings cannot be reset. A new pair_style command for these styles will wipe out all previously specified pair_coeff values.

Here is an alphabetic list of pair styles defined in LAMMPS. They are also listed in more compact form on the Commands pair doc page.

Click on the style to display the formula it computes, any additional arguments specified in the pair_style command, and coefficients specified by the associated pair_coeff command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the Commands pair doc page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- **none** - turn off pairwise interactions
- **hybrid** - multiple styles of pairwise interactions
- **hybrid/overlay** - multiple styles of superposed pairwise interactions
- **zero** - neighbor list but no interactions
- **adp** - angular dependent potential (ADP) of Mishin
- **agni** - machine learned potential mapping atomic environment to forces
- **airebo** - AIREBO potential of Stuart
- **airebo/morse** - AIREBO with Morse instead of LJ
- **atm** - Axilrod-Teller-Muto potential
- **awpmd/cut** - Antisymmetrized Wave Packet MD potential for atoms and electrons
- **beck** - Beck potential
- **body/hparticle** - interactions between body particles
- **body/rounded/polygon** - granular-style 2d polygon potential
- **body/rounded/polycylinder** - granular-style 3d polyhedron potential
- **bop** - BOP potential of Pettifor
- **born** - Born-Mayer-Huggins potential
- **born/coul/dsf** - Born with damped-shifted-force model
- **born/coul/dsf/cs** - Born with damped-shifted-force and core/shell model
- **born/coul/long** - Born with long-range Coulomb
- **born/coul/long/cs** - Born with long-range Coulomb and core/shell model
- **born/coul/msm** - Born with long-range MSM Coulomb
- **born/coul/wolf** - Born with Wolf potential for Coulomb
• *born/coul/wolf/cs* - Born with Wolf potential for Coulomb and core/shell model
• *brownian* - Brownian potential for Fast Lubrication Dynamics
• *brownian/poly* - Brownian potential for Fast Lubrication Dynamics with polydispersity
• *buck* - Buckingham potential
• *buck/coul/cut* - Buckingham with cutoff Coulomb
• *buck/coul/long* - Buckingham with long-range Coulomb
• *buck/coul/long/cs* - Buckingham with long-range Coulomb and core/shell
• *buck/coul/msm* - Buckingham with long-range MSM Coulomb
• *buck/long/coul/long* - long-range Buckingham with long-range Coulomb
• *buck/mdf* - Buckingham with a taper function
• *buck6d/coul/gauss/dsf* - dispersion-damped Buckingham with damped-shift-force model
• *buck6d/coul/gauss/long* - dispersion-damped Buckingham with long-range Coulomb
• *colloid* - integrated colloidal potential
• *comb* - charge-optimized many-body (COMB) potential
• *comb3* - charge-optimized many-body (COMB3) potential
• *cosine/squared* - Cooke-Kremer-Deserno membrane model potential
• *coul/cut* - cutoff Coulomb potential
• *coul/cut/soft* - Coulomb potential with a soft core
• *coul/debye* - cutoff Coulomb potential with Debye screening
• *coul/diel* - Coulomb potential with dielectric permittivity
• *coul/dsf* - Coulomb with damped-shifted-force model
• *coul/long* - long-range Coulomb potential
• *coul/long/cs* - long-range Coulomb potential and core/shell
• *coul/long/soft* - long-range Coulomb potential with a soft core
• *coul/msm* - long-range MSM Coulomb
• *coul/slater/cut* - smeared out Coulomb
• *coul/slater/long* - long-range smeared out Coulomb
• *coul/shield* - Coulomb for boron nitride for use with *ilp/graphene/hbn* potential
• *coul/streitz* - Coulomb via Streitz/Mintmire Slater orbitals
• *coul/wolf* - Coulomb via Wolf potential
• *coul/wolf/cs* - Coulomb via Wolf potential with core/shell adjustments
• *dpd* - dissipative particle dynamics (DPD)
• *dpd/fdt* - DPD for constant temperature and pressure
• *dpd/fdt/energy* - DPD for constant energy and enthalpy
• *dpd/tstat* - pair-wise DPD thermostatting
• *dsmc* - Direct Simulation Monte Carlo (DSMC)
- **e3b** - Explicit-three body (E3B) water model
- **drip** - Dihedral-angle-corrected registry-dependent interlayer potential (DRIP)
- **eam** - embedded atom method (EAM)
- **eam/alloy** - alloy EAM
- **eam/cd** - concentration-dependent EAM
- **eam/cd/old** - older two-site model for concentration-dependent EAM
- **eam/fs** - Finnis-Sinclair EAM
- **edip** - three-body EDIP potential
- **edip/multi** - multi-element EDIP potential
- **edpd** - eDPD particle interactions
- **eff/cut** - electron force field with a cutoff
- **eim** - embedded ion method (EIM)
- **exp6/rx** - reactive DPD potential
- **extep** - extended Tersoff potential
- **gauss** - Gaussian potential
- **gauss/cut** - generalized Gaussian potential
- **gayberne** - Gay-Berne ellipsoidal potential
- **granular** - Generalized granular potential
- **gran/hertz/history** - granular potential with Hertzian interactions
- **gran/hooke** - granular potential with history effects
- **gran/hooke/history** - granular potential without history effects
- **gw** - Gao-Weber potential
- **gw/zbl** - Gao-Weber potential with a repulsive ZBL core
- **hbond/dreiding/lj** - DREIDING hydrogen bonding LJ potential
- **hbond/dreiding/morse** - DREIDING hydrogen bonding Morse potential
- **ilp/graphene/hbn** - registry-dependent interlayer potential (ILP)
- **kim** - interface to potentials provided by KIM project
- **kolmogorov/crespi/full** - Kolmogorov-Crespi (KC) potential with no simplifications
- **kolmogorov/crespi/z** - Kolmogorov-Crespi (KC) potential with normals along z-axis
- **lcbop** - long-range bond-order potential (LCBOP)
- **lebedeva/z** - Lebedeva interlayer potential for graphene with normals along z-axis
- **lennard/mdf** - LJ potential in A/B form with a taper function
- **line/lj** - LJ potential between line segments
- **list** - potential between pairs of atoms explicitly listed in an input file
- **lj/charmm/coul/charmm** - CHARMM potential with cutoff Coulomb
- **lj/charmm/coul/charmm/implicit** - CHARMM for implicit solvent
• \textit{lj/charmm/coul/long} - CHARMM with long-range Coulomb
• \textit{lj/charmm/coul/long/soft} - CHARMM with long-range Coulomb and a soft core
• \textit{lj/charmm/coul/msm} - CHARMM with long-range MSM Coulomb
• \textit{lj/charmmfsw/coul/charmmfsh} - CHARMM with force switching and shifting
• \textit{lj/charmmfsw/coul/long} - CHARMM with force switching and long-range Coulomb
• \textit{lj/class2} - COMPASS (class 2) force field without Coulomb
• \textit{lj/class2/coul/cut} - COMPASS with cutoff Coulomb
• \textit{lj/class2/coul/cut/soft} - COMPASS with cutoff Coulomb with a soft core
• \textit{lj/class2/coul/long} - COMPASS with long-range Coulomb
• \textit{lj/class2/coul/long/cs} - COMPASS with long-range Coulomb with core/shell adjustments
• \textit{lj/class2/coul/long/soft} - COMPASS with long-range Coulomb with a soft core
• \textit{lj/class2/soft} - COMPASS (class 2) force field with no Coulomb with a soft core
• \textit{lj/cubic} - LJ with cubic after inflection point
• \textit{lj/cut} - cutoff Lennard-Jones potential without Coulomb
• \textit{lj/cut/coul/cut} - LJ with cutoff Coulomb
• \textit{lj/cut/coul/cut/soft} - LJ with cutoff Coulomb with a soft core
• \textit{lj/cut/coul/debye} - LJ with Debye screening added to Coulomb
• \textit{lj/cut/coul/dsf} - LJ with Coulomb via damped shifted forces
• \textit{lj/cut/coul/long} - LJ with long-range Coulomb
• \textit{lj/cut/coul/long/cs} - LJ with long-range Coulomb with core/shell adjustments
• \textit{lj/cut/coul/long/soft} - LJ with long-range Coulomb with a soft core
• \textit{lj/cut/coul/msm} - LJ with long-range MSM Coulomb
• \textit{lj/cut/coul/wolf} - LJ with Coulomb via Wolf potential
• \textit{lj/cut/dipole/cut} - point dipoles with cutoff
• \textit{lj/cut/dipole/long} - point dipoles with long-range Ewald
• \textit{lj/cut/soft} - LJ with a soft core
• \textit{lj/cut/thole/long} - LJ with Coulomb with thole damping
• \textit{lj/cut/tip4p/cut} - LJ with cutoff Coulomb for TIP4P water

17.90.4 Restrictions

This command must be used before any coefficients are set by the pair_coeff, read_data, or read_restart commands. Some pair styles are part of specific packages. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info. The doc pages for individual pair potentials tell if it is part of a package.

17.90.5 Related commands

pair_coeff, read_data, pair_modify, kspace_style, dielectric, pair_write

17.90.6 Default

pair_style none

17.91 pair_write command

17.91.1 Syntax

pair_write itype jtype N style inner outer file keyword Qi Qj

• itype,jtype = 2 atom types
• N = # of values
• style = r or rsq or bitmap
• inner,outer = inner and outer cutoff (distance units)
• file = name of file to write values to
• keyword = section name in file for this set of tabulated values
• Qi,Qj = 2 atom charges (charge units) (optional)

17.91.2 Examples

pair_write 1 3 500 r 1.0 10.0 table.txt LJ
pair_write 1 1 1000 rsq 2.0 8.0 table.txt Yukawa_1_1 -0.5 0.5

17.91.3 Description

Write energy and force values to a file as a function of distance for the currently defined pair potential. This is useful for plotting the potential function or otherwise debugging its values. If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file. In case a new file is created, the first line will be a comment containing a “DATE:” and “UNITS:” tag with the current date and the current units setting as argument. For subsequent invocations of the pair_write command, the current units setting is compared against the entry in the file, if present, and pair_write will refuse to add a table if the units are not the same.
The energy and force values are computed at distances from inner to outer for 2 interacting atoms of type itype and jtype, using the appropriate \textit{pair\_coeff} coefficients. If the style is \textit{r}, then N distances are used, evenly spaced in \( r \); if the style is \textit{rsq}, N distances are used, evenly spaced in \( r^2 \).

For example, for \( N = 7 \), style = \textit{r}, inner = 1.0, and outer = 4.0, values are computed at \( r = 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0 \).

If the style is \textit{bitmap}, then \( 2^N \) values are written to the file in a format and order consistent with how they are read in by the \textit{pair\_coeff} command for pair style \textit{table}. For reasonable accuracy in a bitmapped table, choose \( N \geq 12 \), an \textit{inner} value that is smaller than the distance of closest approach of 2 atoms, and an \textit{outer} value \( \leq \) cutoff of the potential.

If the pair potential is computed between charged atoms, the charges of the pair of interacting atoms can optionally be specified. If not specified, values of \( Q_i = Q_j = 1.0 \) are used.

The file is written in the format used as input for the \textit{pair\_style table} option with \textit{keyword} as the section name. Each line written to the file lists an index number (1-\( N \)), a distance (in distance units), an energy (in energy units), and a force (in force units).

\subsection*{17.91.4 Restrictions}

All force field coefficients for pair and other kinds of interactions must be set before this command can be invoked. Due to how the pairwise force is computed, an inner value > 0.0 must be specified even if the potential has a finite value at \( r = 0.0 \).

For EAM potentials, the \textit{pair\_write} command only tabulates the pairwise portion of the potential, not the embedding portion.

\subsection*{17.91.5 Related commands}

\textit{pair\_style table, pair\_style, pair\_coeff}

\subsection*{17.91.6 Default}

\textit{none}

\section*{17.92 partition command}

\subsection*{17.92.1 Syntax}

\begin{verbatim}
partition style N command ...
\end{verbatim}

- \textit{style} = \textit{yes} or \textit{no}
- \( N \) = partition number (see asterisk form below)
- \textit{command} = any LAMMPS command
17.92.2 Examples

```
partition yes 1 processors 4 10 6
partition no 5 print "Active partition"
partition yes +5 fix all nve
partition yes 6* fix all nvt temp 1.0 1.0 0.1
```

17.92.3 Description

This command invokes the specified command on a subset of the partitions of processors you have defined via the `-partition command-line switch`.

Normally, every input script command in your script is invoked by every partition. This behavior can be modified by defining world- or universe-style variables that have different values for each partition. This mechanism can be used to cause your script to jump to different input script files on different partitions, if such a variable is used in a `jump` command.

The “partition” command is another mechanism for having as input script operate differently on different partitions. It is basically a prefix on any LAMMPS command. The command will only be invoked on the partition(s) specified by the style and N arguments.

If the style is yes, the command will be invoked on any partition which matches the N argument. If the style is no the command will be invoked on all the partitions which do not match the Np argument.

Partitions are numbered from 1 to Np, where Np is the number of partitions specified by the `-partition command-line switch`.

N can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or a wild-card asterisk can be used to span a range of partition numbers. This takes the form “*” or “*n” or “n*” or “m*n”. An asterisk with no numeric values means all partitions from 1 to Np. A leading asterisk means all partitions from 1 to n (inclusive). A trailing asterisk means all partitions from n to Np (inclusive). A middle asterisk means all partitions from m to n (inclusive).

This command can be useful for the “run_style verlet/split” command which imposed requirements on how the processors command lays out a 3d grid of processors in each of 2 partitions.

17.92.4 Restrictions

prd 5000 100 10 10 100 1 54982 min 0.1 0.1 100 200
```
17.93.3 Description

Run a parallel replica dynamics (PRD) simulation using multiple replicas of a system. One or more replicas can be used. The total number of steps $N$ to run can be interpreted in one of two ways; see discussion of the `time` keyword below.

PRD is described in (Voter1998) by Art Voter. Similar to global or local hyperdynamics (HD), PRD is a method for performing accelerated dynamics that is suitable for infrequent-event systems that obey first-order kinetics. A good overview of accelerated dynamics methods (AMD) for such systems is given in this review paper (Voter2002) from Art’s group. To quote from the paper: “The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by $p(t) = k \exp(-kt)$ where $k$ is the rate constant.”

Both PRD and HD produce a time-accurate trajectory that effectively extends the timescale over which a system can be simulated, but they do it differently. PRD creates $N_r$ replicas of the system and runs dynamics on each independently with a normal unbiased potential until an event occurs in one of the replicas. The time between events is reduced by a factor of $N_r$ replicas. HD uses a single replica of the system and accelerates time by biasing the interaction potential in a manner such that each timestep is effectively longer. For both methods, per CPU second, more physical time elapses and more events occur. See the hyper doc page for more info about HD.

In PRD, each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the `-partition command-line switch`. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on one or two processors. However for PRD, this makes little sense, since running a replica on virtual instead of physical processors, offers no effective parallel speed-up in searching for infrequent events. See the Howto replica doc page for further discussion.

When a PRD simulation is performed, it is assumed that each replica is running the same model, though LAMMPS does not check for this. I.e. the simulation domain, the number of atoms, the interaction potentials, etc should be the same for every replica.

A PRD run has several stages, which are repeated each time an “event” occurs in one of the replicas, as explained below. The logic for a PRD run is as follows:

```plaintext
while (time remains):
    dephase for n_dephase*t_dephase steps
    until (event occurs on some replica):
        run dynamics for t_event steps
        quench
        check for uncorrelated event on any replica
    until (no correlated event occurs):
        run dynamics for t_correlate steps
        quench
        check for correlated event on this replica
    event replica shares state with all replicas
```

Before this loop begins, the state of the system on replica 0 is shared with all replicas, so that all replicas begin from the same initial state. The first potential energy basin is identified by quenching (an energy minimization, see below) the initial state and storing the resulting coordinates for reference.

In the first stage, dephasing is performed by each replica independently to eliminate correlations between replicas. This is done by choosing a random set of velocities, based on the random_seed that is specified, and running $t_{dephase}$ timesteps of dynamics. This is repeated $n_{dephase}$ times. At each of the $n_{dephase}$ stages, if an event occurs during the $t_{dephase}$ steps of dynamics for a particular replica, the replica repeats the stage until no event occurs.

If the `temp` keyword is not specified, the target temperature for velocity randomization for each replica is the current temperature of that replica. Otherwise, it is the specified $T_{dephase}$ temperature. The style of velocity randomization
LAMMPS Documentation

is controlled using the keyword `vel` with arguments that have the same meaning as their counterparts in the `velocity` command.

In the second stage, each replica runs dynamics continuously, stopping every `t_event` steps to check if a transition event has occurred. This check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin. The first time through the PRD loop, the “previous basin” is the set of quenched coordinates from the initial state of the system.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the `min_style` command. Minimization parameters may be set via the `min_modify` command and by the `min` keyword of the PRD command. The latter are the settings that would be used with the `minimize` command. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event, though you may need to in order to prevent a set of atoms in the system from relaxing to a saddle point.

The event check is performed by a compute with the specified `compute-ID`. Currently there is only one compute that works with the PRD command, which is the `compute event/displace` command. Other event-checking computes may be added. `Compute event/displace` checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an “event” has occurred.

In the third stage, the replica on which the event occurred (event replica) continues to run dynamics to search for correlated events. This is done by running dynamics for `t_correlate` steps, quenching every `t_event` steps, and checking if another event has occurred.

The first time no correlated event occurs, the final state of the event replica is shared with all replicas, the new basin reference coordinates are updated with the quenched state, and the outer loop begins again. While the replica event is searching for correlated events, all the other replicas also run dynamics and event checking with the same schedule, but the final states are always overwritten by the state of the event replica.

The outer loop of the pseudo-code above continues until `N` steps of dynamics have been performed. Note that `N` only includes the dynamics of stages 2 and 3, not the steps taken during dephasing or the minimization iterations of quenching. The specified `N` is interpreted in one of two ways, depending on the `time` keyword. If the `time` value is `steps`, which is the default, then each replica runs for `N` timesteps. If the `time` value is `clock`, then the simulation runs until `N` aggregate timesteps across all replicas have elapsed. This aggregate time is the “clock” time defined below, which typically advances nearly `M` times faster than the timestepping on a single replica, where `M` is the number of replicas.

Four kinds of output can be generated during a PRD run: event statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master `log.lammps` file is limited to event statistics. Note that if a PRD run is performed on only a single replica then the event statistics will be intermixed with the usual thermodynamic output discussed below.

The quantities printed each time an event occurs are the timestep, CPU time, clock, event number, a correlation flag, the number of coincident events, and the replica number of the chosen event.

The timestep is the usual LAMMPS timestep, except that time does not advance during dephasing or quenches, but only during dynamics. Note that there are two kinds of dynamics in the PRD loop listed above that contribute to this timestepping. The first is when all replicas are performing independent dynamics, waiting for an event to occur. The second is when correlated events are being searched for, but only one replica is running dynamics.

The CPU time is the total elapsed time on each processor, since the start of the PRD run.

The clock time is the total elapsed time on each processor, since the start of the PRD run.

The clock is the same as the timestep except that it advances by `M` steps per timestep during the first kind of dynamics when the `M` replicas are running independently. The clock advances by only 1 step per timestep during the second kind of dynamics, when only a single replica is checking for a correlated event. Thus “clock” time represents the aggregate time (in steps) that has effectively elapsed during a PRD simulation on `M` replicas. If most of the PRD run is spent in the second stage of the loop above, searching for infrequent events, then the clock will advance nearly `M`
times faster than it would if a single replica was running. Note the clock time between successive events should be
drawn from p(t).

The event number is a counter that increments with each event, whether it is uncorrelated or correlated.

The correlation flag will be 0 when an uncorrelated event occurs during the second stage of the loop listed above, i.e.
when all replicas are running independently. The correlation flag will be 1 when a correlated event occurs during the
third stage of the loop listed above, i.e. when only one replica is running dynamics.

When more than one replica detects an event at the end of the same event check (every \( t_{\text{event}} \) steps) during the second
stage, then one of them is chosen at random. The number of coincident events is the number of replicas that detected
an event. Normally, this value should be 1. If it is often greater than 1, then either the number of replicas is too large,
or \( t_{\text{event}} \) is too large.

The replica number is the ID of the replica (from 0 to M-1) in which the event occurred.

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. log.lammps.0,
log.lammps.1, etc. For the PRD command, these contain the thermodynamic output for each replica. You will see
short runs and minimizations corresponding to the dynamics and quench operations of the loop listed above. The
timestep will be reset appropriately depending on whether the operation advances time or not.

After the PRD command completes, timing statistics for the PRD run are printed in each replica’s log file, giving a
breakdown of how much CPU time was spent in each stage (dephasing, dynamics, quenching, etc).

Any dump files defined in the input script, will be written to during a PRD run at timesteps corresponding to both
uncorrelated and correlated events. This means the requested dump frequency in the dump command is ignored.
There will be one dump file (per dump command) created for all partitions.

The atom coordinates of the dump snapshot are those of the minimum energy configuration resulting from quenching
following a transition event. The timesteps written into the dump files correspond to the timestep at which the event
occurred and NOT the clock. A dump snapshot corresponding to the initial minimum state used for event detection is
written to the dump file at the beginning of each PRD run.

If the restart command is used, a single restart file for all the partitions is generated, which allows a PRD run to be
continued by a new input script in the usual manner.

The restart file is generated at the end of the loop listed above. If no correlated events are found, this means it contains
a snapshot of the system at time \( T + t_{\text{correlate}} \), where \( T \) is the time at which the uncorrelated event occurred. If
correlated events were found, then it contains a snapshot of the system at time \( T + t_{\text{correlate}} \), where \( T \) is the time of
the last correlated event.

The restart frequency specified in the restart command is interpreted differently when performing a PRD run. It does
not mean the timestep interval between restart files. Instead it means an event interval for uncorrelated events. Thus
a frequency of 1 means write a restart file every time an uncorrelated event occurs. A frequency of 10 means write a
restart file every 10th uncorrelated event.

When an input script reads a restart file from a previous PRD run, the new script can be run on a different number
of replicas or processors. However, it is assumed that \( t_{\text{correlate}} \) in the new PRD command is the same as it was
previously. If not, the calculation of the “clock” value for the first event in the new run will be slightly off.
17.93.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

The \( N \) and \( t_{\text{correlate}} \) settings must be integer multiples of \( t_{\text{event}} \).

Runs restarted from restart file written during a PRD run will not produce identical results due to changes in the random numbers used for dephasing.

This command cannot be used when any fixes are defined that keep track of elapsed time to perform time-dependent operations. Examples include the “ave” fixes such as fix ave/chunk. Also fix dt/reset and fix deposit.

17.93.5 Related commands

compute event/displace, min_modify, min_style, run_style, minimize, velocity, temper, neb, tad, hyper

17.93.6 Default

The option defaults are min = 0.1 0.1 40 50, no temp setting, vel = geom gaussian, and time = steps.

17.94 print command

17.94.1 Syntax

```
print string keyword value
```

- string = text string to print, which may contain variables
- zero or more keyword/value pairs may be appended
- keyword = \textit{file} or \textit{append} or \textit{screen} or \textit{universe}

\begin{itemize}
  \item file value = filename
  \item append value = filename
  \item screen value = yes or no
  \item universe value = yes or no
\end{itemize}

17.94.2 Examples

```
print "Done with equilibration" file info.dat
print Vol=$v append info.dat screen no
print "The system volume is now $v"
print 'The system volume is now $v'
print "NEB calculation 1 complete" screen no universe yes
print ***
System volume = $v
```

(continues on next page)
17.94.3 Description

Print a text string to the screen and logfile. The text string must be a single argument, so if it is one line but more than one word, it should be enclosed in single or double quotes. To generate multiple lines of output, the string can be enclosed in triple quotes, as in the last example above. If the text string contains variables, they will be evaluated and their current values printed.

If the file or append keyword is used, a filename is specified to which the output will be written. If file is used, then the filename is overwritten if it already exists. If append is used, then the filename is appended to if it already exists, or created if it does not exist.

If the screen keyword is used, output to the screen and log file can be turned on or off as desired.

If the universe keyword is used, output to the global screen and log file can be turned on or off as desired. In multi-partition calculations, the screen option and the corresponding output only apply to the screen and log file of the individual partition.

If you want the print command to be executed multiple times (with changing variable values), there are 3 options. First, consider using the fix print command, which will print a string periodically during a simulation. Second, the print command can be used as an argument to the every option of the run command. Third, the print command could appear in a section of the input script that is looped over (see the jump and next commands).

See the variable command for a description of equal style variables which are typically the most useful ones to use with the print command. Equal-style variables can calculate formulas involving mathematical operations, atom properties, group properties, thermodynamic properties, global values calculated by a compute or fix, or references to other variables.

17.95 processors command

17.95.1 Syntax

```
processors Px Py Pz keyword args ...
```

- \( \text{Px,Py,Pz} = \# \text{ of processors in each dimension of 3d grid overlaying the simulation domain} \)
- zero or more keyword/arg pairs may be appended
- \( \text{keyword = grid or map or part or file} \)
- \( \text{grid arg = gstyle params ...} \)
  - \( \text{gstyle = onelevel or twolevel or numa or custom} \)
  - \( \text{onelevel params = none} \)
  - \( \text{twolevel params = Nc Cx Cy Cz} \)
  - \( \text{Nc = number of cores per node} \)
  - \( \text{Cx,Cy,Cz = \# of cores in each dimension of 3d sub-grid assigned to each node} \)
  - \( \text{numa params = none} \)
  - \( \text{custom params = infile} \)
  - \( \text{infile = file containing grid layout} \)
- \( \text{map arg = cart or cart/reorder or xyz or xzy or yxz or yzx or zxy or zyx} \)
  - \( \text{cart = use MPI_Cart() methods to map processors to 3d grid with reorder = 0} \)
  - \( \text{cart/reorder = use MPI_Cart() methods to map processors to 3d grid with reorder = 1} \)
  - \( \text{xyz,xzy,yxz,yzx,zxy,zyx = map processors to 3d grid in IJK ordering} \)
  - \( \text{numa arg = none} \)
- \( \text{part args = Psend Precv cstyle} \)
  - \( \text{Psend = partition \# (1 to Np) which will send its processor layout} \)
  - \( \text{Precv = partition \# (1 to Np) which will recv the processor layout} \)
  - \( \text{cstyle = multiple} \)
    - \( \text{multiple = Psend grid will be multiple of Precv grid in each dimension} \)
- \( \text{file arg = outfile} \)
  - \( \text{outfile = name of file to write 3d grid of processors to} \)

17.95.2 Examples

```
processors 5
processors 2 4 4
processors 8 map xyz
processors grid numa
processors grid twolevel 4
processors 4 8 16 grid custom myfile
processors part 1 2 multiple
```
17.95.3 Description

Specify how processors are mapped as a regular 3d grid to the global simulation box. The mapping involves 2 steps. First if there are P processors it means choosing a factorization P = Px by Py by Pz so that there are Px processors in the x dimension, and similarly for the y and z dimensions. Second, the P processors are mapped to the regular 3d grid. The arguments to this command control each of these 2 steps.

The Px, Py, Pz parameters affect the factorization. Any of the 3 parameters can be specified with an asterisk “*”, which means LAMMPS will choose the number of processors in that dimension of the grid. It will do this based on the size and shape of the global simulation box so as to minimize the surface-to-volume ratio of each processor’s sub-domain.

Choosing explicit values for Px or Py or Pz can be used to override the default manner in which LAMMPS will create the regular 3d grid of processors, if it is known to be sub-optimal for a particular problem. E.g. a problem where the extent of atoms will change dramatically in a particular dimension over the course of the simulation.

The product of Px, Py, Pz must equal P, the total # of processors LAMMPS is running on. For a 2d simulation, Pz must equal 1.

Note that if you run on a prime number of processors P, then a grid such as 1 x P x 1 will be required, which may incur extra communication costs due to the high surface area of each processor’s sub-domain.

Also note that if multiple partitions are being used then P is the number of processors in this partition; see the -partition command-line switch doc page for details. Also note that you can prefix the processors command with the partition command to easily specify different Px,Py,Pz values for different partitions.

You can use the partition command to specify different processor grids for different partitions, e.g.

```
partition yes 1 processors 4 4 4
partition yes 2 processors 2 3 2
```

Note: This command only affects the initial regular 3d grid created when the simulation box is first specified via a create_box or read_data or read_restart command. Or if the simulation box is re-created via the replicate command. The same regular grid is initially created, regardless of which comm_style command is in effect.

If load-balancing is never invoked via the balance or fix balance commands, then the initial regular grid will persist for all simulations. If balancing is performed, some of the methods invoked by those commands retain the logical topology of the initial 3d grid, and the mapping of processors to the grid specified by the processors command. However the grid spacings in different dimensions may change, so that processors own sub-domains of different sizes. If the comm_style tiled command is used, methods invoked by the balancing commands may discard the 3d grid of processors and tile the simulation domain with sub-domains of different sizes and shapes which no longer have a logical 3d connectivity. If that occurs, all the information specified by the processors command is ignored.

The grid keyword affects the factorization of P into Px,Py,Pz and it can also affect how the P processor IDs are mapped to the 3d grid of processors.

The onelevel style creates a 3d grid that is compatible with the Px,Py,Pz settings, and which minimizes the surface-to-volume ratio of each processor’s sub-domain, as described above. The mapping of processors to the grid is determined by the map keyword setting.

The twolevel style can be used on machines with multicore nodes to minimize off-node communication. It insures that contiguous sub-sections of the 3d grid are assigned to all the cores of a node. For example if Nc is 4, then 2x2x1 or 2x1x2 or 1x2x2 sub-sections of the 3d grid will correspond to the cores of each node. This affects both the factorization and mapping steps.

The Cx, Cy, Cz settings are similar to the Px, Py, Pz settings, only their product should equal Nc. Any of the 3 parameters can be specified with an asterisk “*”, which means LAMMPS will choose the number of cores in that
dimension of the node’s sub-grid. As with Px,Py,Pz, it will do this based on the size and shape of the global simulation box so as to minimize the surface-to-volume ratio of each processor’s sub-domain.

**Note:** For the `twolevel` style to work correctly, it assumes the MPI ranks of processors LAMMPS is running on are ordered by core and then by node. E.g. if you are running on 2 quad-core nodes, for a total of 8 processors, then it assumes processors 0,1,2,3 are on node 1, and processors 4,5,6,7 are on node 2. This is the default rank ordering for most MPI implementations, but some MPIS provide options for this ordering, e.g. via environment variable settings.

The `numa` style operates similar to the `twolevel` keyword except that it auto-detects which cores are running on which nodes. Currently, it does this in only 2 levels, but it may be extended in the future to account for socket topology and other non-uniform memory access (NUMA) costs. It also uses a different algorithm than the `twolevel` keyword for doing the two-level factorization of the simulation box into a 3d processor grid to minimize off-node communication, and it does its own MPI-based mapping of nodes and cores to the regular 3d grid. Thus it may produce a different layout of the processors than the `twolevel` options.

The `numa` style will give an error if the number of MPI processes is not divisible by the number of cores used per node, or any of the Px or Py of Pz values is greater than 1.

**Note:** Unlike the `twolevel` style, the `numa` style does not require any particular ordering of MPI ranks in order to work correctly. This is because it auto-detects which processes are running on which nodes.

The `custom` style uses the file `infile` to define both the 3d factorization and the mapping of processors to the grid.

The file should have the following format. Any number of initial blank or comment lines (starting with a “#” character) can be present. The first non-blank, non-comment line should have 3 values:

```
P x  P y  P z
```

These must be compatible with the total number of processors and the Px, Py, Pz settings of the processors command. This line should be immediately followed by P = Px*Py*Pz lines of the form:

```
I D  I  J  K
```

where ID is a processor ID (from 0 to P-1) and I,J,K are the processors location in the 3d grid. I must be a number from 1 to Px (inclusive) and similarly for J and K. The P lines can be listed in any order, but no processor ID should appear more than once.

The `map` keyword affects how the P processor IDs (from 0 to P-1) are mapped to the 3d grid of processors. It is only used by the `onelevel` and `twolevel` grid settings.

The `cart` style uses the family of MPI Cartesian functions to perform the mapping, namely MPI_Cart_create(), MPI_Cart_get(), MPI_Cart_shift(), and MPI_Cart_rank(). It invokes the MPI_Cart_create() function with its reorder flag = 0, so that MPI is not free to reorder the processors.

The `cart/reorder` style does the same thing as the `cart` style except it sets the reorder flag to 1, so that MPI can reorder processors if it desires.

The `xyz`, `xzy`, `yxz`, `yzx`, `zxy`, and `zyx` styles are all similar. If the style is IJK, then it maps the P processors to the grid so that the processor ID in the I direction varies fastest, the processor ID in the J direction varies next fastest, and the processor ID in the K direction varies slowest. For example, if you select style `xyz` and you have a 2x2x2 grid of 8 processors, the assignments of the 8 octants of the simulation domain will be:
Note that, in principle, an MPI implementation on a particular machine should be aware of both the machine’s network topology and the specific subset of processors and nodes that were assigned to your simulation. Thus its MPI_Cart calls can optimize the assignment of MPI processes to the 3d grid to minimize communication costs. In practice, however, few if any MPI implementations actually do this. So it is likely that the cart and cart/reorder styles simply give the same result as one of the IJK styles.

Also note, that for the twolvel grid style, the map setting is used to first map the nodes to the 3d grid, then again to the cores within each node. For the latter step, the cart and cart/reorder styles are not supported, so an xyz style is used in their place.

The part keyword affects the factorization of P into Px,Py,Pz.

It can be useful when running in multi-partition mode, e.g. with the run_style verlet/split command. It specifies a dependency between a sending partition Psend and a receiving partition Preccv which is enforced when each is setting up their own mapping of their processors to the simulation box. Each of Psend and Preccv must be integers from 1 to Np, where Np is the number of partitions you have defined via the -partition command-line switch.

A “dependency” means that the sending partition will create its regular 3d grid as Px by Py by Pz and after it has done this, it will send the Px,Py,Pz values to the receiving partition. The receiving partition will wait to receive these values before creating its own regular 3d grid and will use the sender’s Px,Py,Pz values as a constraint. The nature of the constraint is determined by the cstyle argument.

For a cstyle of multiple, each dimension of the sender’s processor grid is required to be an integer multiple of the corresponding dimension in the receiver’s processor grid. This is a requirement of the run_style verlet/split command.

For example, assume the sending partition creates a 4x6x10 grid = 240 processor grid. If the receiving partition is running on 80 processors, it could create a 4x2x10 grid, but it will not create a 2x4x10 grid, since in the y-dimension, 6 is not an integer multiple of 4.

Note: If you use the partition command to invoke different “processors” commands on different partitions, and you also use the part keyword, then you must insure that both the sending and receiving partitions invoke the “processors” command that connects the 2 partitions via the part keyword. LAMMPS cannot easily check for this, but your simulation will likely hang in its setup phase if this error has been made.

The file keyword writes the mapping of the factorization of P processors and their mapping to the 3d grid to the specified file outfile. This is useful to check that you assigned physical processors in the manner you desired, which can be tricky to figure out, especially when running on multiple partitions or on, a multicore machine or when the processor ranks were reordered by use of the -reorder command-line switch or due to use of MPI-specific launch options such as a config file.

If you have multiple partitions you should insure that each one writes to a different file, e.g. using a world-style variable for the filename. The file has a self-explanatory header, followed by one-line per processor in this format:

world-ID universe-ID original-ID: I J K: name
The IDs are the processor’s rank in this simulation (the world), the universe (of multiple simulations), and the original MPI communicator used to instantiate LAMMPS, respectively. The world and universe IDs will only be different if you are running on more than one partition; see the \texttt{-partition command-line switch}. The universe and original IDs will only be different if you used the \texttt{-reorder command-line switch} to reorder the processors differently than their rank in the original communicator LAMMPS was instantiated with.

I,J,K are the indices of the processor in the regular 3d grid, each from 1 to Nd, where Nd is the number of processors in that dimension of the grid.

The \textit{name} is what is returned by a call to MPI\_Get\_processor\_name() and should represent an identifier relevant to the physical processors in your machine. Note that depending on the MPI implementation, multiple cores can have the same \textit{name}.

\section*{17.95.4 Restrictions}
This command cannot be used after the simulation box is defined by a \texttt{read\_data} or \texttt{create\_box} command. It can be used before a restart file is read to change the 3d processor grid from what is specified in the restart file.

The \texttt{grid numa} keyword only currently works with the \texttt{map cart} option.

The \texttt{part} keyword (for the receiving partition) only works with the \texttt{grid onelevel} or \texttt{grid twolevel} options.

\section*{17.95.5 Related commands}
\texttt{partition, -reorder command-line switch}

\section*{17.95.6 Default}
The option defaults are \texttt{Px Py Pz = * * *}, \texttt{grid = onelevel}, and \texttt{map = cart}.

```
17.96.3 Description

Define a Python function or execute a previously defined function or execute some arbitrary python code. Arguments, including LAMMPS variables, can be passed to the function from the LAMMPS input script and a value returned by the Python function to a LAMMPS variable. The Python code for the function can be included directly in the input script or in a separate Python file. The function can be standard Python code or it can make “callbacks” to LAMMPS through its library interface to query or set internal values within LAMMPS. This is a powerful mechanism for performing complex operations in a LAMMPS input script that are not possible with the simple input script and variable syntax which LAMMPS defines. Thus your input script can operate more like a true programming language.

Use of this command requires building LAMMPS with the PYTHON package which links to the Python library so that the Python interpreter is embedded in LAMMPS. More details about this process are given below.

There are two ways to invoke a Python function once it has been defined. One is using the invoke keyword. The other is to assign the function to a python-style variable defined in your input script. Whenever the variable is evaluated, it will execute the Python function to assign a value to the variable. Note that variables can be evaluated in many different ways within LAMMPS. They can be substituted for directly in an input script. Or they can be passed to various commands as arguments, so that the variable is evaluated during a simulation run.

A broader overview of how Python can be used with LAMMPS is given on the Python doc page. There is an examples/python directory which illustrates use of the python command.

The func setting specifies the name of the Python function. The code for the function is defined using the file or here keywords as explained below. In case of the source keyword, the name of the function is ignored.

If the invoke keyword is used, no other keywords can be used, and a previous python command must have defined the Python function referenced by this command. This invokes the Python function with the previously defined arguments and return value processed as explained below. You can invoke the function as many times as you wish in your input script.

If the source keyword is used, no other keywords can be used. The argument can be a filename or a string with python commands, either on a single line enclosed in quotes, or as multiple lines enclosed in triple quotes. These python commands will be passed to the python interpreter and executed immediately without registering a python function for future execution.

The input keyword defines how many arguments N the Python function expects. If it takes no arguments, then the input keyword should not be used. Each argument can be specified directly as a value, e.g. 6 or 3.14159 or abc (a string of characters). The type of each argument is specified by the format keyword as explained below, so that Python will know how to interpret the value. If the word SELF is used for an argument it has a special meaning. A pointer is passed to the Python function which it converts into a reference to LAMMPS itself. This enables the function to call back to LAMMPS through its library interface as explained below. This allows the Python function to query or set values internal to LAMMPS which can affect the subsequent execution of the input script. A LAMMPS variable can also be used as an argument, specified as v_name, where “name” is the name of the variable. Any style of LAMMPS variable can be used, as defined by the variable command. Each time the Python function is invoked, the LAMMPS variable is evaluated and its value is passed to the Python function.

The return keyword is only needed if the Python function returns a value. The specified varReturn must be of the form v_name, where “name” is the name of a python-style LAMMPS variable, defined by the variable command. The Python function can return a numeric or string value, as specified by the format keyword.

As explained on the variable doc page, the definition of a python-style variable associates a Python function name with the variable. This must match the func setting for this command. For example these two commands would be self-consistent:

```bash
variable foo python myMultiply
python myMultiply return v_foo format f file funcs.py
```
The two commands can appear in either order in the input script so long as both are specified before the Python function is invoked for the first time.

The format keyword must be used if the input or return keyword is used. It defines an fstring with M characters, where M = sum of number of inputs and outputs. The order of characters corresponds to the N inputs, followed by the return value (if it exists). Each character must be one of the following: “i” for integer, “f” for floating point, “s” for string, or “p” for SELF. Each character defines the type of the corresponding input or output value of the Python function and affects the type conversion that is performed internally as data is passed back and forth between LAMMPS and Python. Note that it is permissible to use a python-style variable in a LAMMPS command that allows for an equal-style variable as an argument, but only if the output of the Python function is flagged as a numeric value (“i” or “f”) via the format keyword.

If the return keyword is used and the format keyword specifies the output as a string, then the default maximum length of that string is 63 characters (64-1 for the string terminator). If you want to return a longer string, the length keyword can be specified with its Nlen value set to a larger number (the code allocates space for Nlen+1 to include the string terminator). If the Python function generates a string longer than the default 63 or the specified Nlen, it will be truncated.

Either the file, here, or exists keyword must be used, but only one of them. These keywords specify what Python code to load into the Python interpreter. The file keyword gives the name of a file, which should end with a “.py” suffix, which contains Python code. The code will be immediately loaded into and run in the “main” module of the Python interpreter. Note that Python code which contains a function definition does not “execute” the function when it is run; it simply defines the function so that it can be invoked later.

The here keyword does the same thing, except that the Python code follows as a single argument to the here keyword. This can be done using triple quotes as delimiters, as in the examples above. This allows Python code to be listed verbatim in your input script, with proper indentation, blank lines, and comments, as desired. See the Commands parse doc page, for an explanation of how triple quotes can be used as part of input script syntax.

The exists keyword takes no argument. It means that Python code containing the required Python function defined by the func setting, is assumed to have been previously loaded by another python command.

Note that the Python code that is loaded and run must contain a function with the specified func name. To operate properly when later invoked, the function code must match the input and return and format keywords specified by the python command. Otherwise Python will generate an error.

This section describes how Python code can be written to work with LAMMPS.

Whether you load Python code from a file or directly from your input script, via the file and here keywords, the code can be identical. It must be indented properly as Python requires. It can contain comments or blank lines. If the code is in your input script, it cannot however contain triple-quoted Python strings, since that will conflict with the triple-quote parsing that the LAMMPS input script performs.

All the Python code you specify via one or more python commands is loaded into the Python “main” module, i.e. _main_. The code can define global variables or statements that are outside of function definitions. It can contain multiple functions, only one of which matches the func setting in the python command. This means you can use the file keyword once to load several functions, and the exists keyword thereafter in subsequent python commands to access the other functions previously loaded.

A Python function you define (or more generally, the code you load) can import other Python modules or classes, it can make calls to other system functions or functions you define, and it can access or modify global variables (in the “main” module) which will persist between successive function calls. The latter can be useful, for example, to prevent a function from being invoke multiple times per timestep by different commands in a LAMMPS input script that access the returned python-style variable associated with the function. For example, consider this function loaded with two global variables defined outside the function:
Nsteplast stores the previous timestep the function was invoked (passed as an argument to the function). Nvaluelast stores the return value computed on the last function invocation. If the function is invoked again on the same timestep, the previous value is simply returned, without re-computing it. The “global” statement inside the Python function allows it to overwrite the global variables.

Note that if you load Python code multiple times (via multiple python commands), you can overwrite previously loaded variables and functions if you are not careful. E.g. if the code above were loaded twice, the global variables would be re-initialized, which might not be what you want. Likewise, if a function with the same name exists in two chunks of Python code you load, the function loaded second will override the function loaded first.

It’s important to realize that if you are running LAMMPS in parallel, each MPI task will load the Python interpreter and execute a local copy of the Python function(s) you define. There is no connection between the Python interpreters running on different processors. This implies three important things.

First, if you put a print statement in your Python function, you will see P copies of the output, when running on P processors. If the prints occur at (nearly) the same time, the P copies of the output may be mixed together. Welcome to the world of parallel programming and debugging.

Second, if your Python code loads modules that are not pre-loaded by the Python library, then it will load the module from disk. This may be a bottleneck if 1000s of processors try to load a module at the same time. On some large supercomputers, loading of modules from disk by Python may be disabled. In this case you would need to pre-build a Python library that has the required modules pre-loaded and link LAMMPS with that library.

Third, if your Python code calls back to LAMMPS (discussed in the next section) and causes LAMMPS to perform an MPI operation requires global communication (e.g. via MPI_Allreduce), such as computing the global temperature of the system, then you must insure all your Python functions (running independently on different processors) call back to LAMMPS. Otherwise the code may hang.

Your Python function can “call back” to LAMMPS through its library interface, if you use the SELF input to pass Python a pointer to LAMMPS. The mechanism for doing this in your Python function is as follows:

```
def foo(lmpptr,...):
    from lammps import lammps
    lmp = lammps(ptr=lmpptr)
    lmp.command('print "Hello from inside Python"')
    ...
```

The function definition must include a variable (lmpptr in this case) which corresponds to SELF in the python command. The first line of the function imports the Python module lammps.py in the python directory of the distribution. The second line creates a Python object “lmp” which wraps the instance of LAMMPS that called the function. The “ptr=lmpptr” argument is what makes that happen. The third line invokes the command() function in the LAMMPS library interface. It takes a single string argument which is a LAMMPS input script command for LAMMPS to execute, the same as if it appeared in your input script. In this case, LAMMPS should output
Hello from inside Python

to the screen and log file. Note that since the LAMMPS print command itself takes a string in quotes as its argument, the Python string must be delimited with a different style of quotes.

The Python library doc page describes the syntax for how Python wraps the various functions included in the LAMMPS library interface.

A more interesting example is in the examples/python/in.python script which loads and runs the following function from examples/python/funcs.py:

```python
def loop(N,cut0,thresh,lmpptr):
    print "LOOP ARGS",N,cut0,thresh,lmpptr
    from lammps import lammps
    lmp = lammps(ptr=lmpptr)
    natoms = lmp.get_natoms()

    for i in range(N):
        cut = cut0 + i*0.1

        lmp.set_variable("cut",cut)  # set a variable in LAMMPS
        lmp.command("pair_style lj/cut ${cut}")  # LAMMPS command
        #lmp.command("pair_style lj/cut %d" % cut)  # LAMMPS command option

        lmp.command("pair_coeff * * 1.0 1.0")  # ditto
        lmp.command("run 10")  # ditto
        pe = lmp.extract_compute("thermo_pe",0,0)  # extract total PE from LAMMPS
        print "PE",pe/natoms,thresh
        if pe/natoms < thresh:
            return
```

with these input script commands:

```bash
python loop input 4 10 1.0 -4.0 SELF format iffp file funcs.py
python loop invoke
```

This has the effect of looping over a series of 10 short runs (10 timesteps each) where the pair style cutoff is increased from a value of 1.0 in distance units, in increments of 0.1. The looping stops when the per-atom potential energy falls below a threshold of -4.0 in energy units. More generally, Python can be used to implement a loop with complex logic, much more so than can be created using the LAMMPS jump and if commands.

Several LAMMPS library functions are called from the loop function. Get_natoms() returns the number of atoms in the simulation, so that it can be used to normalize the potential energy that is returned by extract_compute() for the “thermo_pe” compute that is defined by default for LAMMPS thermodynamic output. Set_variable() sets the value of a string variable defined in LAMMPS. This library function is a useful way for a Python function to return multiple values to LAMMPS, more than the single value that can be passed back via a return statement. This cutoff value in the “cut” variable is then substituted (by LAMMPS) in the pair_style command that is executed next. Alternatively, the “LAMMPS command option” line could be used in place of the 2 preceding lines, to have Python insert the value into the LAMMPS command string.

Note: When using the callback mechanism just described, recognize that there are some operations you should not attempt because LAMMPS cannot execute them correctly. If the Python function is invoked between runs in the LAMMPS input script, then it should be OK to invoke any LAMMPS input script command via the library interface command() or file() functions, so long as the command would work if it were executed in the LAMMPS input script directly at the same point.

However, a Python function can also be invoked during a run, whenever an associated LAMMPS variable it is assigned
to is evaluated. If the variable is an input argument to another LAMMPS command (e.g. `fix setforce`), then the Python function will be invoked inside the class for that command, in one of its methods that is invoked in the middle of a timestep. You cannot execute arbitrary input script commands from the Python function (again, via the command() or file() functions) at that point in the run and expect it to work. Other library functions such as those that invoke computes or other variables may have hidden side effects as well. In these cases, LAMMPS has no simple way to check that something illogical is being attempted.

The same applies to Python functions called during a simulation run at each time step using `fix python/invoke`.

If you run Python code directly on your workstation, either interactively or by using Python to launch a Python script stored in a file, and your code has an error, you will typically see informative error messages. That is not the case when you run Python code from LAMMPS using an embedded Python interpreter. The code will typically fail silently. LAMMPS will catch some errors but cannot tell you where in the Python code the problem occurred. For example, if the Python code cannot be loaded and run because it has syntax or other logic errors, you may get an error from Python pointing to the offending line, or you may get one of these generic errors from LAMMPS:

```
Could not process Python file
Could not process Python string
```

When the Python function is invoked, if it does not return properly, you will typically get this generic error from LAMMPS:

```
Python function evaluation failed
```

Here are three suggestions for debugging your Python code while running it under LAMMPS.

First, don’t run it under LAMMPS, at least to start with! Debug it using plain Python. Load and invoke your function, pass it arguments, check return values, etc.

Second, add Python print statements to the function to check how far it gets and intermediate values it calculates. See the discussion above about printing from Python when running in parallel.

Third, use Python exception handling. For example, say this statement in your Python function is failing, because you have not initialized the variable `foo`:

```
foo += 1
```

If you put one (or more) statements inside a “try” statement, like this:

```
import exceptions
print "Inside simple function"
try:
    foo += 1          # one or more statements here
except Exception, e:
    print "FOO error:",e
```

then you will get this message printed to the screen:

```
FOO error: local variable 'foo' referenced before assignment
```

If there is no error in the try statements, then nothing is printed. Either way the function continues on (unless you put a return or `sys.exit()` in the except clause).
17.96.4 Restrictions

This command is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Building LAMMPS with the PYTHON package will link LAMMPS with the Python library on your system. Settings to enable this are in the lib/python/Makefile.lammps file. See the lib/python/README file for information on those settings.

If you use Python code which calls back to LAMMPS, via the SELF input argument explained above, there is an extra step required when building LAMMPS. LAMMPS must also be built as a shared library and your Python function must be able to load the Python module in python/lammps.py that wraps the LAMMPS library interface. These are the same steps required to use Python by itself to wrap LAMMPS. Details on these steps are explained on the Python doc page. Note that it is important that the stand-alone LAMMPS executable and the LAMMPS shared library be consistent (built from the same source code files) in order for this to work. If the two have been built at different times using different source files, problems may occur.

17.96.5 Related commands

shell, variable, fix python/invoke

17.96.6 Default

none

17.97 quit command

17.97.1 Syntax

```
quit status
```

status = numerical exit status (optional)

17.97.2 Examples

```
quit
if "$n > 10000" then "quit 1"
```

17.97.3 Description

This command causes LAMMPS to exit, after shutting down all output cleanly.

It can be used as a debug statement in an input script, to terminate the script at some intermediate point.

It can also be used as an invoked command inside the “then” or “else” portion of an if command.

The optional status argument is an integer which signals the return status to a program calling LAMMPS. A return status of 0 usually indicates success. A status != 0 is failure, where the specified value can be used to distinguish the kind of error, e.g. where in the input script the quit was invoked. If not specified, a status of 0 is returned.

17.98.3 Description

Read in a data file containing information LAMMPS needs to run a simulation. The file can be ASCII text or a gzipped text file (detected by a .gz suffix). This is one of 3 ways to specify initial atom coordinates; see the read_restart and create_atoms commands for alternative methods. Also see the explanation of the -restart command-line switch which can convert a restart file to a data file.

This command can be used multiple times to add new atoms and their properties to an existing system by using the add, offset, and shift keywords. See more details below, which includes the use case for the extra keywords.

The group keyword adds all the atoms in the data file to the specified group-ID. The group will be created if it does not already exist. This is useful if you are reading multiple data files and wish to put sets of atoms into different groups so they can be operated on later. E.g. a group of added atoms can be moved to new positions via the displace_atoms command. Note that atoms read from the data file are also always added to the “all” group. The group command discusses atom groups, as used in LAMMPS.

The nocoeff keyword tells read_data to ignore force field parameters. The various Coeff sections are still read and have to have the correct number of lines, but they are not applied. This also allows to read a data file without having any pair, bond, angle, dihedral or improper styles defined, or to read a data file for a different force field.

The use of the fix keyword is discussed below.

17.98.4 Reading multiple data files

The read_data command can be used multiple times with the same or different data files to build up a complex system from components contained in individual data files. For example one data file could contain fluid in a confined domain; a second could contain wall atoms, and the second file could be read a third time to create a wall on the other side of the fluid. The third set of atoms could be rotated to an opposing direction using the displace_atoms command, after the third read_data command is used.

The add, offset, shift, extra, and group keywords are useful in this context.
If a simulation box does not yet exist, the *add* keyword cannot be used; the *read_data* command is being used for the first time. If a simulation box does exist, due to using the *create_box* command, or a previous *read_data* command, then the *add* keyword must be used.

**Note:** The simulation box size (xlo to xhi, ylo to yhi, zlo to zhi) in the new data file will be merged with the existing simulation box to create a large enough box in each dimension to contain both the existing and new atoms. Each box dimension never shrinks due to this merge operation, it only stays the same or grows. Care must be used if you are growing the existing simulation box in a periodic dimension. If there are existing atoms with bonds that straddle that periodic boundary, then the atoms may become far apart if the box size grows. This will separate the atoms in the bond, which can lead to “lost” bond atoms or bad dynamics.

The three choices for the *add* argument affect how the atom IDs and molecule IDs of atoms in the data file are treated. If *append* is specified, atoms in the data file are added to the current system, with their atom IDs reset so that an atom-ID = M in the data file becomes atom-ID = N+M, where N is the largest atom ID in the current system. This rule is applied to all occurrences of atom IDs in the data file, e.g. in the Velocity or Bonds section. This is also done for molecule IDs, if the atom style does support molecule IDs or they are enabled via *fix property/atom*. If *IDoffset* is specified, then *IDoffset* is a numeric value is given, e.g. 1000, so that an atom-ID = M in the data file becomes atom-ID = 1000+M. For systems with enabled molecule IDs, another numerical argument *MOLOffset* is required representing the equivalent offset for molecule IDs. If *merge* is specified, the data file atoms are added to the current system without changing their IDs. They are assumed to merge (without duplication) with the currently defined atoms. It is up to you to insure there are no multiply defined atom IDs, as LAMMPS only performs an incomplete check that this is the case by insuring the resulting max atom-ID >= the number of atoms. For molecule IDs, there is no check done at all. The *offset* and *shift* keywords can only be used if the *add* keyword is also specified.

The *offset* keyword adds the specified offset values to the atom types, bond types, angle types, dihedral types, and improper types as they are read from the data file. E.g. if toff = 2, and the file uses atom types 1,2,3, then the added atoms will have atom types 3,4,5. These offsets apply to all occurrences of types in the data file, e.g. for the Atoms or Masses or Pair Coeffs or Bond Coeffs sections. This makes it easy to use atoms and molecules and their attributes from a data file in different simulations, where you want their types (atom, bond, angle, etc) to be different depending on what other types already exist. All five offset values must be specified, but individual values will be ignored if the data file does not use that attribute (e.g. no bonds).

The *shift* keyword can be used to specify an (Sx, Sy, Sz) displacement applied to the coordinates of each atom. Sz must be 0.0 for a 2d simulation. This is a mechanism for adding structured collections of atoms at different locations within the simulation box, to build up a complex geometry. It is up to you to insure atoms do not end up overlapping unphysically which would lead to bad dynamics. Note that the *displace_atoms* command can be used to move a subset of atoms after they have been read from a data file. Likewise, the *delete_atoms* command can be used to remove overlapping atoms. Note that the shift values (Sx, Sy, Sz) are also added to the simulation box information (xlo, xhi, ylo, yhi, zlo, zhi) in the data file to shift its boundaries. E.g. xlo_new = xlo + Sx, xhi_new = xhi + Sx.

The *extra* keywords can only be used the first time the *read_data* command is used. They are useful if you intend to add new atom, bond, angle, etc types later with additional *read_data* commands. This is because the maximum number of allowed atom, bond, angle, etc types is set by LAMMPS when the system is first initialized. If you do not use the *extra* keywords, then the number of these types will be limited to what appears in the first data file you read. For example, if the first data file is a solid substrate of Si, it will likely specify a single atom type. If you read a second data file with a different material (water molecules) that sit on top of the substrate, you want to use different atom types for those atoms. You can only do this if you set the *extra/atom/types* keyword to a sufficiently large value when reading the substrate data file. Note that use of the *extra* keywords also allows each data file to contain sections like Masses or Pair Coeffs or Bond Coeffs which are sized appropriately for the number of types in that data file. If the *offset* keyword is used appropriately when each data file is read, the values in those sections will be stored correctly in the larger data structures allocated by the use of the *extra* keywords. E.g. the substrate file can list mass and pair coefficients for type 1 silicon atoms. The water file can list mass and pair coefficients for type 1 and type 2 hydrogen and oxygen atoms. Use of the *extra* and *offset* keywords will store those mass and pair coefficient values appropriately in data structures that allow for 3 atom types (Si, H, O). Of course, you would still need to specify coefficients for H/Si
and O/Si interactions in your input script to have a complete pairwise interaction model.

An alternative to using the *extra* keywords with the *read_data* command, is to use the *create_box* command to initialize the simulation box and all the various type limits you need via its *extra* keywords. Then use the *read_data* command one or more times to populate the system with atoms, bonds, angles, etc, using the *offset* keyword if desired to alter types used in the various data files you read.

### 17.98.5 Format of a data file

The structure of the data file is important, though many settings and sections are optional or can come in any order. See the examples directory for sample data files for different problems.

A data file has a header and a body. The header appears first. The first line of the header is always skipped; it typically contains a description of the file. Then lines are read one at a time. Lines can have a trailing comment starting with ‘#’ that is ignored. If the line is blank (only white-space after comment is deleted), it is skipped. If the line contains a header keyword, the corresponding value(s) is read from the line. If it does not contain a header keyword, the line begins the body of the file.

The body of the file contains zero or more sections. The first line of a section has only a keyword. This line can have a trailing comment starting with ‘#’ that is either ignored or can be used to check for a style match, as described below. The next line is skipped. The remaining lines of the section contain values. The number of lines depends on the section keyword as described below. Zero or more blank lines can be used between sections. Sections can appear in any order, with a few exceptions as noted below.

The keyword *fix* can be used one or more times. Each usage specifies a fix that will be used to process a specific portion of the data file. Any header line containing *header-string* and any section with a name containing *section-string* will be passed to the specified fix. See the *fix property/atom* command for an example of a fix that operates in this manner. The doc page for the fix defines the syntax of the header line(s) and section(s) that it reads from the data file. Note that the *header-string* can be specified as NULL, in which case no header lines are passed to the fix. This means that it can infer the length of its Section from standard header settings, such as the number of atoms.

The formatting of individual lines in the data file (indentation, spacing between words and numbers) is not important except that header and section keywords (e.g. atoms, xlo xhi, Masses, Bond Coefs) must be capitalized as shown and can’t have extra white-space between their words - e.g. two spaces or a tab between the 2 words in “xlo xhi” or the 2 words in “Bond Coefs”, is not valid.

### 17.98.6 Format of the header of a data file

These are the recognized header keywords. Header lines can come in any order. The value(s) are read from the beginning of the line. Thus the keyword *atoms* should be in a line like “1000 atoms”; the keyword *ylo yhi* should be in a line like “-10.0 10.0 ylo yhi”; the keyword *xy xz yz* should be in a line like “0.0 5.0 6.0 xy xz yz”. All these settings have a default value of 0, except the lo/hi box size defaults are -0.5 and 0.5. A line need only appear if the value is different than the default.

- *atoms* = # of atoms in system
- *bonds* = # of bonds in system
- *angles* = # of angles in system
- *dihedrals* = # of dihedrals in system
- *impropers* = # of impropers in system
atom types = # of atom types in system
bond types = # of bond types in system
angle types = # of angle types in system
dihedral types = # of dihedral types in system
improper types = # of improper types in system
extra bond per atom = leave space for this many new bonds per atom (deprecated, use extra/bond/per/atom keyword)
extra angle per atom = leave space for this many new angles per atom (deprecated, use extra/angle/per/atom keyword)
extra dihedral per atom = leave space for this many new dihedrals per atom (deprecated, use extra/dihedral/per/atom keyword)
extra improper per atom = leave space for this many new impropers per atom (deprecated, use extra/improper/per/atom keyword)
extra special per atom = leave space for this many new special bonds per atom (deprecated, use extra/special/per/atom keyword)
extra bond per atom = leave space for this many new special bonds per atom (deprecated, use extra/special/per/atom keyword)
ellipsoids = # of ellipsoids in system
lines = # of line segments in system
triangles = # of triangles in system
bodies = # of bodies in system
xlo xhi = simulation box boundaries in x dimension
ylo yhi = simulation box boundaries in y dimension
zlo zhi = simulation box boundaries in z dimension
xy xz yz = simulation box tilt factors for triclinic system

The initial simulation box size is determined by the lo/hi settings. In any dimension, the system may be periodic or non-periodic; see the boundary command. When the simulation box is created it is also partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors being used and the settings of the processors command. The partitioning can later be changed by the balance or fix balance commands.

If the xy xz yz line does not appear, LAMMPS will set up an axis-aligned (orthogonal) simulation box. If the line does appear, LAMMPS creates a non-orthogonal simulation domain shaped as a parallelepiped with triclinic symmetry. The parallelepiped has its “origin” at (xlo,ylo,zlo) and is defined by 3 edge vectors starting from the origin given by A = (xhi-xlo,0,0); B = (xy,yhi-ylo,0); C = (xz,yz,zhi-zlo). Xy,xz,yz can be 0.0 or positive or negative values and are called “tilt factors” because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped.

By default, the tilt factors (xy,xz,yz) can not skew the box more than half the distance of the corresponding parallel box length. For example, if xlo = 2 and xhi = 12, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between -(xhi-xlo)/2 and +(yhi-ylo)/2. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all geometrically equivalent. If you wish to define a box with tilt factors that exceed these limits, you can use the box tilt command, with a setting of large; a setting of small is the default.

See the Howto triclinic doc page for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

When a triclinic system is used, the simulation domain should normally be periodic in the dimension that the tilt is applied to, which is given by the second dimension of the tilt factor (e.g. y for xy tilt). This is so that pairs of atoms
interacting across that boundary will have one of them shifted by the tilt factor. Periodicity is set by the boundary
command. For example, if the xy tilt factor is non-zero, then the y dimension should be periodic. Similarly, the z
dimension should be periodic if xz or yz is non-zero. LAMMPS does not require this periodicity, but you may lose
atoms if this is not the case.

Also note that if your simulation will tilt the box, e.g. via the fix deform command, the simulation box must be setup
to be triclinic, even if the tilt factors are initially 0.0. You can also change an orthogonal box to a triclinic box or vice
versa by using the change box command with its ortho and triclinic options.

For 2d simulations, the zlo zhi values should be set to bound the z coords for atoms that appear in the file; the default
of -0.5 0.5 is valid if all z coords are 0.0. For 2d triclinic simulations, the xz and yz tilt factors must be 0.0.

If the system is periodic (in a dimension), then atom coordinates can be outside the bounds (in that dimension); they
will be remapped (in a periodic sense) back inside the box. Note that if the add option is being used to add atoms to
a simulation box that already exists, this periodic remapping will be performed using simulation box bounds that are
the union of the existing box and the box boundaries in the new data file.

Note: If the system is non-periodic (in a dimension), then all atoms in the data file must have coordinates (in that
dimension) that are “greater than or equal to” the lo value and “less than or equal to” the hi value. If the non-periodic
dimension is of style “fixed” (see the boundary command), then the atom coords must be strictly “less than” the hi
value, due to the way LAMMPS assign atoms to processors. Note that you should not make the lo/hi values radically
smaller/larger than the extent of the atoms. For example, if your atoms extend from 0 to 50, you should not specify
the box bounds as -10000 and 10000. This is because LAMMPS uses the specified box size to layout the 3d grid of
processors. A huge (mostly empty) box will be sub-optimal for performance when using “fixed” boundary conditions
(see the boundary command). When using “shrink-wrap” boundary conditions (see the boundary command), a huge
(mostly empty) box may cause a parallel simulation to lose atoms when LAMMPS shrink-wraps the box around the
atoms. The read_data command will generate an error in this case.

The “extra bond per atom” setting (angle, dihedral, improper) is only needed if new bonds (angles, dihedrals, im-
propers) will be added to the system when a simulation runs, e.g. by using the fix bond/create command. Using this
header flag is deprecated; please use the extra/bond/per/atom keyword (and correspondingly for angles, dihedrals and
impropers) in the read_data command instead. Either will pre-allocate space in LAMMPS data structures for storing
the new bonds (angles, dihedrals, impropers).

The “extra special per atom” setting is typically only needed if new bonds/angles/etc will be added to the system, e.g.
by using the fix bond/create command. Or if entire new molecules will be added to the system, e.g. by using the fix
deposit or fix pour commands, which will have more special 1-2,1-3,1-4 neighbors than any other molecules defined
in the data file. Using this header flag is deprecated; please use the extra/special/per/atom keyword instead. Using this
setting will pre-allocate space in the LAMMPS data structures for storing these neighbors. See the special_bonds and
molecule doc pages for more discussion of 1-2,1-3,1-4 neighbors.

Note: All of the “extra” settings are only applied in the first data file read and when no simulation box has yet been
created; as soon as the simulation box is created (and read_data implies that), these settings are locked and cannot be
changed anymore. Please see the description of the add keyword above for reading multiple data files. If they appear
in later data files, they are ignored.

The “ellipsoids” and “lines” and “triangles” and “bodies” settings are only used with atom_style ellipsoid or line or
tri or body and specify how many of the atoms are finite-size ellipsoids or lines or triangles or bodies; the remainder
are point particles. See the discussion of ellipsoidflag and the Ellipsoids section below. See the discussion of lineflag
and the Lines section below. See the discussion of triangleflag and the Triangles section below. See the discussion of
bodyflag and the Bodies section below.
Note: For atom_style template, the molecular topology (bonds, angles, etc) is contained in the molecule templates read-in by the molecule command. This means you cannot set the bonds, angles, etc header keywords in the data file, nor can you define Bonds, Angles, etc sections as discussed below. You can set the bond types, angle types, etc header keywords, though it is not necessary. If specified, they must match the maximum values defined in any of the template molecules.

17.98.7 Format of the body of a data file

These are the section keywords for the body of the file.

- Atoms, Velocities, Masses, Ellipsoids, Lines, Triangles, Bodies = atom-property sections
- Bonds, Angles, Dihedrals, Impropers = molecular topology sections
- Pair Coeffs, PairIJ Coeffs, Bond Coeffs, Angle Coeffs, Dihedral Coeffs, Improper Coeffs = force field sections
- BondBond Coeffs, BondAngle Coeffs, MiddleBondTorsion Coeffs, EndBondTorsion Coeffs, AngleTorsion Coeffs,
  AngleAngleTorsion Coeffs, BondBond13 Coeffs, AngleAngle Coeffs = class 2 force field sections

These keywords will check an appended comment for a match with the currently defined style:

- Atoms, Pair Coeffs, PairIJ Coeffs, Bond Coeffs, Angle Coeffs, Dihedral Coeffs, Improper Coeffs

For example, these lines:

```
Atoms # sphere
Pair Coeffs # lj/cut
```

will check if the currently-defined atom_style is sphere, and the current pair_style is lj/cut. If not, LAMMPS will issue a warning to indicate that the data file section likely does not contain the correct number or type of parameters expected for the currently-defined style.

Each section is listed below in alphabetic order. The format of each section is described including the number of lines it must contain and rules (if any) for where it can appear in the data file.

Any individual line in the various sections can have a trailing comment starting with “#” for annotation purposes. E.g. in the Atoms section:

```
10 1 17 -1.0 10.0 5.0 6.0 # salt ion
```

Angle Coeffs section:

- one line per angle type
- line syntax: ID coeffs
  
  ID = angle type (1-N)
  coeffs = list of coeffs

- example:

```
6 70 108.5 0 0
```
The number and meaning of the coefficients are specific to the defined angle style. See the `angle_style` and `angle_coeff` commands for details. Coefficients can also be set via the `angle_coeff` command in the input script.

**AngleAngle Coeffs section:**
- one line per improper type
- line syntax: ID coeffs
  
  ID = improper type (1-N)
  coeffs = list of coeffs (see `improper_coeff`)

**AngleAngleTorsion Coeffs section:**
- one line per dihedral type
- line syntax: ID coeffs
  
  ID = dihedral type (1-N)
  coeffs = list of coeffs (see `dihedral_coeff`)

**Angles section:**
- one line per angle
- line syntax: ID type atom1 atom2 atom3

  ID = number of angle (1-Nangles)
  type = angle type (1-Nangletype)
  atom1,atom2,atom3 = IDs of 1st,2nd,3rd atom in angle

  example:

  2 2 17 29 430

  The 3 atoms are ordered linearly within the angle. Thus the central atom (around which the angle is computed) is the atom2 in the list. E.g. H,O,H for a water molecule. The Angles section must appear after the Atoms section. All values in this section must be integers (1, not 1.0).

**AngleTorsion Coeffs section:**
- one line per dihedral type
- line syntax: ID coeffs

  ID = dihedral type (1-N)
  coeffs = list of coeffs (see `dihedral_coeff`)

**Atoms section:**
- one line per atom
- line syntax: depends on atom style
An *Atoms* section must appear in the data file if natoms > 0 in the header section. The atoms can be listed in any order. These are the line formats for each *atom style* in LAMMPS. As discussed below, each line can optionally have 3 flags (nx,ny,nz) appended to it, which indicate which image of a periodic simulation box the atom is in. These may be important to include for some kinds of analysis.

</table>

The per-atom values have these meanings and units, listed alphabetically:

- **atom-ID** = integer ID of atom
- **atom-type** = type of atom (1-Ntype)
- **bodyflag** = 1 for body particles, 0 for point particles
- **ccN** = chemical concentration for tDPD particles for each species (mole/volume units)
- **contact-radius** = ??? (distance units)
- **cs_re,cs_im** = real/imaginary parts of wave packet coefficients
- **cv** = heat capacity (need units) for SPH particles
- **density** = density of particle (mass/distance^3 or mass/distance^2 or mass/distance units, depending on dimensionality of particle)
- **diameter** = diameter of spherical atom (distance units)
- **esph** = energy (need units) for SPH particles
- **edpd_temp** = temperature for eDPD particles (temperature units)
- **edpd_cv** = volumetric heat capacity for eDPD particles (energy/temperature/volume units)
- **ellipsoidflag** = 1 for ellipsoidal particles, 0 for point particles
- **eradius** = electron radius (or fixed-core radius)
• etag = integer ID of electron that each wave packet belongs to
• kernel-radius = ??? (distance units)
• lineflag = 1 for line segment particles, 0 for point or spherical particles
• mass = mass of particle (mass units)
• molecule-ID = integer ID of molecule the atom belongs to
• mux,muy,muz = components of dipole moment of atom (dipole units)
• q = charge on atom (charge units)
• rho = density (need units) for SPH particles
• spin = electron spin (+1/-1), 0 = nuclei, 2 = fixed-core, 3 = pseudo-cores (i.e. ECP)
• sp = magnitude of magnetic spin of atom (Bohr magnetons)
• spx,spy,spz = components of magnetic spin of atom (unit vector)
• template-atom = which atom within a template molecule the atom is
• template-index = which molecule within the molecule template the atom is part of
• theta = internal temperature of a DPD particle
• triangleflag = 1 for triangular particles, 0 for point or spherical particles
• volume = volume of Peridynamic particle (distance^3 units)
• x,y,z = coordinates of atom (distance units)
• x0,y0,z0 = original (strain-free) coordinates of atom (distance units)

The units for these quantities depend on the unit style; see the units command for details.

For 2d simulations specify z as 0.0, or a value within the zlo zhi setting in the data file header.

The atom-ID is used to identify the atom throughout the simulation and in dump files. Normally, it is a unique value from 1 to Natoms for each atom. Unique values larger than Natoms can be used, but they will cause extra memory to be allocated on each processor, if an atom map array is used, but not if an atom map hash is used; see the atom_modify command for details. If an atom map is not used (e.g. an atomic system with no bonds), and you don’t care if unique atom IDs appear in dump files, then the atom-IDs can all be set to 0.

The molecule ID is a second identifier attached to an atom. Normally, it is a number from 1 to N, identifying which molecule the atom belongs to. It can be 0 if it is a non-bonded atom or if you don’t care to keep track of molecule assignments.

The diameter specifies the size of a finite-size spherical particle. It can be set to 0.0, which means that atom is a point particle.

The ellipsoidflag, lineflag, triangleflag, and bodyflag determine whether the particle is a finite-size ellipsoid or line or triangle or body of finite size, or whether the particle is a point particle. Additional attributes must be defined for each ellipsoid, line, triangle, or body in the corresponding Ellipsoids, Lines, Triangles, or Bodies section.

The template-index and template-atom are only defined used by atom_style template. In this case the molecule command is used to define a molecule template which contains one or more molecules. If an atom belongs to one of those molecules, its template-index and template-atom are both set to positive integers; if not the values are both 0. The template-index is which molecule (1 to Nmols) the atom belongs to. The template-atom is which atom (1 to Natoms) within the molecule the atom is.

Some pair styles and fixes and computes that operate on finite-size particles allow for a mixture of finite-size and point particles. See the doc pages of individual commands for details.
For finite-size particles, the density is used in conjunction with the particle volume to set the mass of each particle as mass = density * volume. In this context, volume can be a 3d quantity (for spheres or ellipsoids), a 2d quantity (for triangles), or a 1d quantity (for line segments). If the volume is 0.0, meaning a point particle, then the density value is used as the mass. One exception is for the body atom style, in which case the mass of each particle (body or point particle) is specified explicitly. This is because the volume of the body is unknown.

Note that for 2d simulations of spheres, this command will treat them as spheres when converting density to mass. However, they can also be modeled as 2d discs (circles) if the set density/disc command is used to reset their mass after the read_data command is used. A disc keyword can also be used with time integration fixes, such as fix nve/sphere and fix nvt/sphere to time integrate their motion as 2d discs (not 3d spheres), by changing their moment of inertia.

For atom_style hybrid, following the 5 initial values (ID,type,x,y,z), specific values for each sub-style must be listed. The order of the sub-styles is the same as they were listed in the atom_style command. The specific values for each sub-style are those that are not the 5 standard ones (ID,type,x,y,z). For example, for the “charge” sub-style, a “q” value would appear. For the “full” sub-style, a “molecule-ID” and “q” would appear. These are listed in the same order they appear as listed above. Thus if

```
atom_style hybrid charge sphere
```

were used in the input script, each atom line would have these fields:

```
atom-ID atom-type x y z q diameter density
```

Note that if a non-standard value is defined by multiple sub-styles, it only appears once in the atom line. E.g. the atom line for atom_style hybrid dipole full would list “q” only once, with the dipole sub-style fields; “q” does not appear with the full sub-style fields.

```
atom-ID atom-type x y z q mux muy myz molecule-ID
```

Atom lines specify the (x,y,z) coordinates of atoms. These can be inside or outside the simulation box. When the data file is read, LAMMPS wraps coordinates outside the box back into the box for dimensions that are periodic. As discussed above, if an atom is outside the box in a non-periodic dimension, it will be lost.

LAMMPS always stores atom coordinates as values which are inside the simulation box. It also stores 3 flags which indicate which image of the simulation box (in each dimension) the atom would be in if its coordinates were unwrapped across periodic boundaries. An image flag of 0 means the atom is still inside the box when unwrapped. A value of 2 means add 2 box lengths to get the unwrapped coordinate. A value of -1 means subtract 1 box length to get the unwrapped coordinate. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation. The dump command can output atom coordinates in wrapped or unwrapped form, as well as the 3 image flags.

In the data file, atom lines (all lines or none of them) can optionally list 3 trailing integer values (nx,ny,nz), which are used to initialize the atom’s image flags. If nx,ny,nz values are not listed in the data file, LAMMPS initializes them to 0. Note that the image flags are immediately updated if an atom’s coordinates need to wrapped back into the simulation box.

It is only important to set image flags correctly in a data file if a simulation model relies on unwrapped coordinates for some calculation; otherwise they can be left unspecified. Examples of LAMMPS commands that use unwrapped coordinates internally are as follows:

- Atoms in a rigid body (see fix rigid, fix rigid/small) must have consistent image flags, so that when the atoms are unwrapped, they are near each other, i.e. as a single body.

- If the replicate command is used to generate a larger system, image flags must be consistent for bonded atoms when the bond crosses a periodic boundary. I.e. the values of the image flags should be different by 1 (in the appropriate dimension) for the two atoms in such a bond.

- If you plan to dump image flags and perform post-analysis that will unwrap atom coordinates, it may be important that a continued run (restarted from a data file) begins with image flags that are consistent with the previous run.
**Note:** If your system is an infinite periodic crystal with bonds then it is impossible to have fully consistent image flags. This is because some bonds will cross periodic boundaries and connect two atoms with the same image flag.

Atom velocities and other atom quantities not defined above are set to 0.0 when the *Atoms* section is read. Velocities can be set later by a *Velocities* section in the data file or by a *velocity* or *set* command in the input script.

**Bodies** section:
- one or more lines per body
- first line syntax: atom-ID Ninteger Ndouble

| Ninteger = # of integer quantities for this particle |
| Ndouble = # of floating-point quantities for this particle |

- 0 or more integer lines with total of Ninteger values
- 0 or more double lines with total of Ndouble values
- example:

```
12 3 6
2 3 2
1.0 2.0 3.0 1.0 2.0 4.0
```

- example:

```
12 0 14
1.0 2.0 3.0 1.0 2.0 4.0 1.0
2.0 3.0 1.0 2.0 4.0 4.0 2.0
```

The *Bodies* section must appear if *atom_style body* is used and any atoms listed in the *Atoms* section have a bodyflag = 1. The number of bodies should be specified in the header section via the “bodies” keyword.

Each body can have a variable number of integer and/or floating-point values. The number and meaning of the values is defined by the body style, as described in the *Howto body* doc page. The body style is given as an argument to the *atom_style body* command.

The Ninteger and Ndouble values determine how many integer and floating-point values are specified for this particle. Ninteger and Ndouble can be as large as needed and can be different for every body. Integer values are then listed next on subsequent lines. Lines are read one at a time until Ninteger values are read. Floating-point values follow on subsequent lines, Again lines are read one at a time until Ndouble values are read. Note that if there are no values of a particular type, no lines appear for that type.

The *Bodies* section must appear after the *Atoms* section.

**Bond Coeffs** section:
- one line per bond type
- line syntax: ID coeffs

| ID = bond type (1-N) |
| coeffs = list of coeffs |

- example:
The number and meaning of the coefficients are specific to the defined bond style. See the bond_style and bond_coeff commands for details. Coefficients can also be set via the bond_coeff command in the input script.

**BondAngle Coeffs** section:
- one line per angle type
- line syntax: ID coeffs

  ID = angle type (1-N)
  coeffs = list of coeffs (see class 2 section of angle_coeff)

**BondBond Coeffs** section:
- one line per angle type
- line syntax: ID coeffs

  ID = angle type (1-N)
  coeffs = list of coeffs (see class 2 section of angle_coeff)

**BondBond13 Coeffs** section:
- one line per dihedral type
- line syntax: ID coeffs

  ID = dihedral type (1-N)
  coeffs = list of coeffs (see class 2 section of dihedral_coeff)

**Bonds** section:
- one line per bond
- line syntax: ID type atom1 atom2

  ID = bond number (1-Nbonds)
  type = bond type (1-Nbondtype)
  atom1, atom2 = IDs of 1st, 2nd atom in bond

  example:

  12 3 17 29

The Bonds section must appear after the Atoms section. All values in this section must be integers (1, not 1.0).

**Dihedral Coeffs** section:
- one line per dihedral type
- line syntax: ID coeffs
ID = dihedral type (1-N)
coeffs = list of coeffs

- example:

| 3 | 0.6 | 1 | 0 | 1 |

The number and meaning of the coefficients are specific to the defined dihedral style. See the `dihedral_style` and `dihedral_coeff` commands for details. Coefficients can also be set via the `dihedral_coeff` command in the input script.

**Dihedrals section:**

- one line per dihedral
- line syntax: ID type atom1 atom2 atom3 atom4

| ID = number of dihedral (1-N_dihedrals) | type = dihedral type (1-N_dihedraltype) | atom1,atom2,atom3,atom4 = IDs of 1st,2nd,3rd,4th atom in dihedral |

- example:

| 12 | 4 | 17 | 29 | 30 | 21 |

The 4 atoms are ordered linearly within the dihedral. The **Dihedrals** section must appear after the **Atoms** section. All values in this section must be integers (1, not 1.0).

**Ellipsoids section:**

- one line per ellipsoid
- line syntax: atom-ID shapex shapey shapez quatw quati quatj quatk

| atom-ID = ID of atom which is an ellipsoid | shapex,shapey,shapez = 3 diameters of ellipsoid (distance units) | quatw,quati,quatj,quatk = quaternion components for orientation of atom |

- example:

| 12 | 1 | 2 | 1 | 1 | 0 | 0 | 0 |

The **Ellipsoids** section must appear if `atom_style ellipsoid` is used and any atoms are listed in the **Atoms** section with an ellipsoidflag = 1. The number of ellipsoids should be specified in the header section via the “ellipsoids” keyword. The 3 shape values specify the 3 diameters or aspect ratios of a finite-size ellipsoidal particle, when it is oriented along the 3 coordinate axes. They must all be non-zero values.

The values `quatw`, `quati`, `quatj`, and `quatk` set the orientation of the atom as a quaternion (4-vector). Note that the shape attributes specify the aspect ratios of an ellipsoidal particle, which is oriented by default with its x-axis along the simulation box’s x-axis, and similarly for y and z. If this body is rotated (via the right-hand rule) by an angle theta around a unit vector (a,b,c), then the quaternion that represents its new orientation is given by (cos(theta/2), a*sin(theta/2), b*sin(theta/2), c*sin(theta/2)). These 4 components are `quatw`, `quati`, `quatj`, and `quatk` as specified above. LAMMPS normalizes each atom’s quaternion in case (a,b,c) is not specified as a unit vector.

The **Ellipsoids** section must appear after the **Atoms** section.

**EndBondTorsion Coeffs section:**
• one line per dihedral type
• line syntax: ID coeffs
  
  ID = dihedral type (1-N)
  coeffs = list of coeffs (see class 2 section of dihedral_coeff)

**Improper Coeffs** section:

• one line per improper type
• line syntax: ID coeffs

  ID = improper type (1-N)
  coeffs = list of coeffs

• example:

  2 20 0.0548311

The number and meaning of the coefficients are specific to the defined improper style. See the improper_style and improper_coeff commands for details. Coefficients can also be set via the improper_coeff command in the input script.

**Impropers** section:

• one line per improper
• line syntax: ID type atom1 atom2 atom3 atom4

  ID = number of improper (1-Nimpropers)
  type = improper type (1-Nimpropertype)
  atom1,atom2,atom3,atom4 = IDs of 1st,2nd,3rd,4th atom in improper

• example:

  12 3 17 29 13 100

The ordering of the 4 atoms determines the definition of the improper angle used in the formula for each improper style. See the doc pages for individual styles for details.

The Impropers section must appear after the Atoms section. All values in this section must be integers (1, not 1.0).

**Lines** section:

• one line per line segment
• line syntax: atom-ID x1 y1 x2 y2

  atom-ID = ID of atom which is a line segment
  x1,y1 = 1st end point
  x2,y2 = 2nd end point

• example:

  12 1.0 0.0 2.0 0.0
The \textit{Lines} section must appear if \textit{atom_style line} is used and any atoms are listed in the \textit{Atoms} section with a lineflag = 1. The number of lines should be specified in the header section via the “lines” keyword.

The 2 end points are the end points of the line segment. The ordering of the 2 points should be such that using a right-hand rule to cross the line segment with a unit vector in the +z direction, gives an “outward” normal vector perpendicular to the line segment. I.e. normal = (c2-c1) x (0,0,1). This orientation may be important for defining some interactions.

The \textit{Lines} section must appear after the \textit{Atoms} section.

\textit{Masses} section:

- one line per atom type
- line syntax: ID mass

\begin{verbatim}
ID = atom type (1-N)  
mass = mass value
\end{verbatim}

- example:

\begin{verbatim}
3 1.01
\end{verbatim}

This defines the mass of each atom type. This can also be set via the \textit{mass} command in the input script. This section cannot be used for atom styles that define a mass for individual atoms - e.g. \textit{atom_style sphere}.

\textit{MiddleBondTorsion Coeffs} section:

- one line per dihedral type
- line syntax: ID coeffs

\begin{verbatim}
ID = dihedral type (1-N)  
coeffs = list of coeffs (see class 2 section of dihedral_coeff)
\end{verbatim}

\textit{Pair Coeffs} section:

- one line per atom type
- line syntax: ID coeffs

\begin{verbatim}
ID = atom type (1-N)  
coeffs = list of coeffs
\end{verbatim}

- example:

\begin{verbatim}
3 0.022 2.35197 0.022 2.35197
\end{verbatim}

The number and meaning of the coefficients are specific to the defined pair style. See the \textit{pair_style} and \textit{pair_coeff} commands for details. Since pair coefficients for types I != J are not specified, these will be generated automatically by the pair style’s mixing rule. See the individual pair_style doc pages and the \textit{pair_modify mix} command for details. Pair coefficients can also be set via the \textit{pair_coeff} command in the input script.

\textit{PairIJ Coeffs} section:

- one line per pair of atom types for all I,J with I <= J
• line syntax: ID1 ID2 coeffs

<table>
<thead>
<tr>
<th>ID1 = atom type I = 1-N</th>
<th>ID2 = atom type J = I-N, with I &lt;= J</th>
</tr>
</thead>
<tbody>
<tr>
<td>coeffs = list of coeffs</td>
<td></td>
</tr>
</tbody>
</table>

• examples:

| 3 3 0.022 2.35197 0.022 2.35197 |
| 3 5 0.022 2.35197 0.022 2.35197 |

This section must have N*(N+1)/2 lines where N = # of atom types. The number and meaning of the coefficients are specific to the defined pair style. See the pair_style and pair_coeff commands for details. Since pair coefficients for types I != J are all specified, these values will turn off the default mixing rule defined by the pair style. See the individual pair_style doc pages and the pair_modify mix command for details. Pair coefficients can also be set via the pair_coeff command in the input script.

Triangles section:

• one line per triangle

• line syntax: atom-ID x1 y1 z1 x2 y2 z2 x3 y3 z3

| atom-ID = ID of atom which is a line segment |
| x1,y1,z1 = 1st corner point |
| x2,y2,z2 = 2nd corner point |
| x3,y3,z3 = 3rd corner point |

• example:

| 12 0.0 0.0 0.0 2.0 0.0 1.0 0.0 2.0 1.0 |

The Triangles section must appear if atom_style tri is used and any atoms are listed in the Atoms section with a triangleflag = 1. The number of lines should be specified in the header section via the “triangles” keyword.

The 3 corner points are the corner points of the triangle. The ordering of the 3 points should be such that using a right-hand rule to go from point1 to point2 to point3 gives an “outward” normal vector to the face of the triangle. I.e. normal = (c2-c1) x (c3-c1). This orientation may be important for defining some interactions.

The Triangles section must appear after the Atoms section.

Velocities section:

• one line per atom

• line syntax: depends on atom style

| all styles except those listed | atom-ID vx vy vz |
| electron | atom-ID vx vy vz ervel |
| ellipsoid | atom-ID vx vy vz lx ly lz |
| sphere | atom-ID vx vy vz wx wy wz |
| hybrid | atom-ID vx vy vz sub-style1 sub-style2 . . . |

where the keywords have these meanings:
vx, vy, vz = translational velocity of atom
lx, ly, lz = angular momentum of aspherical atom
wx, wy, wz = angular velocity of spherical atom
ervel = electron radial velocity (0 for fixed-core): ul

The velocity lines can appear in any order. This section can only be used after an Atoms section. This is because the Atoms section must have assigned a unique atom ID to each atom so that velocities can be assigned to them.

Vx, vy, vz, and ervel are in units of velocity. Lx, ly, lz are in units of angular momentum (distance-velocity-mass). Wx, Wy, Wz are in units of angular velocity (radians/time).

For atom_style hybrid, following the 4 initial values (ID, vx, vy, vz), specific values for each sub-style must be listed. The order of the sub-styles is the same as they were listed in the atom_style command. The sub-style specific values are those that are not the 5 standard ones (ID, vx, vy, vz). For example, for the “sphere” sub-style, “wx”, “wy”, “wz” values would appear. These are listed in the same order they appear as listed above. Thus if

```
atom_style hybrid electron sphere
```

were used in the input script, each velocity line would have these fields:

```
atom-ID vx vy vz ervel wx wy wz
```

Translational velocities can also be set by the velocity command in the input script.

---

17.98.8 Restrictions

To read gzipped data files, you must compile LAMMPS with the -DLAMMPS_GZIP option. See the Build settings doc page for details.

17.98.9 Related commands

```
read_dump, read_restart, create_atoms, write_data
```

17.98.10 Default

The default for all the extra keywords is 0.

17.99 read_dump command

17.99.1 Syntax

```
read_dump file Nstep field1 field2 ... keyword values ...
```

- file = name of dump file to read
- Nstep = snapshot timestep to read from file
- one or more fields may be appended

```
field = x or y or z or vx or vy or vz or q or ix or iy or iz or fx or fy, or fz
        x, y, z = atom coordinates
        vx, vy, vz = velocity components
```

---

796 Chapter 17. Commands
q = charge
ix, iy, iz = image flags in each dimension
fx, fy, fz = force components

- zero or more keyword/value pairs may be appended
- keyword = nfile or box or replace or purge or trim or add or label or scaled or wrapped or format
  
nfile value = Nfiles = how many parallel dump files exist
  box value = yes or no = replace simulation box with dump box
  replace value = yes or no = overwrite atoms with dump atoms
  purge value = yes or no = delete all atoms before adding dump atoms
  trim value = yes or no = trim atoms not in dump snapshot
  add value = yes or keep or no = add new dump atoms to system
  label value = field column
    field = one of the listed fields or id or type
    column = label on corresponding column in dump file
  scaled value = yes or no = coords in dump file are scaled/unscaled
  wrapped value = yes or no = coords in dump file are wrapped/unwraped
  format values = format of dump file, must be last keyword if used
    native = native LAMMPS dump file
    xyz = XYZ file
    adios [timeout value] = dump file written by the dump adios command
      timeout = specify waiting time for the arrival of the timestep when running concurrently.
      The value is a float number and is interpreted in seconds.
  molfile style path = VMD molfile plugin interface
    style = dcd or xyz or others supported by molfile plugins
    path = optional path for location of molfile plugins

17.99.2 Examples

```plaintext
read_dump dump.file 5000 x y z
read_dump dump.xyz 5 x y z box no format xyz
read_dump dump.xyz 10 x y z box no format molfile xyz "./plugins"
read_dump dump.dcd 0 x y z box yes format molfile dcd
read_dump dump.file 1000 x y z vx vy vz box yes format molfile lammpstrj /usr/local/
  lib/vmd/plugins/LINUXAMD64/plugins/molfile
read_dump dump.file 5000 x y vx vy trim yes
read_dump ../run7/dump.file.gz 10000 x y z box yes
read_dump dump.xyz 10 x y z box no format molfile xyz ../plugins
read_dump dump.dcd 0 x y z format molfile dcd
read_dump dump.file 1000 x y z vx vy vz format molfile lammpstrj /usr/local/lib/vmd/
  LINUXAMD64/plugins/molfile
read_dump dump.bp 5000 x y z vx vy vz format adios
read_dump dump.bp 5000 x y z vx vy vz format adios timeout 60.0
```
17.99.3 Description

Read atom information from a dump file to overwrite the current atom coordinates, and optionally the atom velocities and image flags and the simulation box dimensions. This is useful for restarting a run from a particular snapshot in a dump file. See the read_restart and read_data commands for alternative methods to do this. Also see the rerun command for a means of reading multiple snapshots from a dump file.

Note that a simulation box must already be defined before using the read_dump command. This can be done by the create_box, read_data, or read_restart commands. The read_dump command can reset the simulation box dimensions, as explained below.

Also note that reading per-atom information from a dump snapshot is limited to the atom coordinates, velocities and image flags, as explained below. Other atom properties, which may be necessary to run a valid simulation, such as atom charge, or bond topology information for a molecular system, are not read from (or even contained in) dump files. Thus this auxiliary information should be defined in the usual way, e.g. in a data file read in by a read_data command, before using the read_dump command, or by the set command, after the dump snapshot is read.

If the dump filename specified as file ends with “.gz”, the dump file is read in gzipped format. You cannot (yet) read a dump file that was written in binary format with a “.bin” suffix.

You can read dump files that were written (in parallel) to multiple files via the “%” wild-card character in the dump file name. If any specified dump file name contains a “%”, they must all contain it. See the dump command for details. The “%” wild-card character is only supported by the native format for dump files, described next.

If reading parallel dump files, you must also use the nfile keyword to tell LAMMPS how many parallel files exist, via its specified Nfiles value.

The format of the dump file is selected through the format keyword. If specified, it must be the last keyword used, since all remaining arguments are passed on to the dump reader. The native format is for native LAMMPS dump files, written with a dump atom or dump custom command. The xyz format is for generic XYZ formatted dump files. These formats take no additional values.

The molfile format supports reading data through using the VMD molfile plugin interface. This dump reader format is only available, if the USER-MOLFILE package has been installed when compiling LAMMPS.

The molfile format takes one or two additional values. The style value determines the file format to be used and can be any format that the molfile plugins support, such as DCD or XYZ. Note that DCD dump files can be written by LAMMPS via the dump dcd command. The path value specifies a list of directories which LAMMPS will search for the molfile plugins appropriate to the specified style. The syntax of the path value is like other search paths: it can contain multiple directories separated by a colon (or semi-colon on windows). The path keyword is optional and defaults to “.”, i.e. the current directory.

The adios format supports reading data that was written by the dump adios command. The entire dump is read in parallel across all the processes, dividing the atoms evenly among the processes. The number of writers that has written the dump file does not matter. Using the adios style for dump and read_dump is a convenient way to dump all atoms from N writers and read it back by M readers. If one is running two LAMMPS instances concurrently where one dumps data and the other is reading it with the rerun command, the timeout option can be specified to wait on the reader side for the arrival of the requested step.

Support for other dump format readers may be added in the future.

Global information is first read from the dump file, namely timestep and box information.

The dump file is scanned for a snapshot with a timestamp that matches the specified Nstep. This means the LAMMPS timestep the dump file snapshot was written on for the native or adios formats.

The list of timestamps available in an adios .bp file is stored in the variable ntimestep:
Note that the *xyz* and *molfile* formats do not store the timestep. For these formats, timesteps are numbered logically, in a sequential manner, starting from 0. Thus to access the 10th snapshot in an *xyz* or *molfile* formatted dump file, use \( N\text{step} = 9 \).

The dimensions of the simulation box for the selected snapshot are also read; see the *box* keyword discussion below. For the *native* format, an error is generated if the snapshot is for a triclinic box and the current simulation box is orthogonal or vice versa. A warning will be generated if the snapshot box boundary conditions (periodic, shrink-wrapped, etc) do not match the current simulation boundary conditions, but the boundary condition information in the snapshot is otherwise ignored. See the “boundary” command for more details. The *adios* reader does the same as the *native* format reader.

For the *xyz* format, no information about the box is available, so you must set the *box* flag to *no*. See details below.

For the *molfile* format, reading simulation box information is typically supported, but the location of the simulation box origin is lost and no explicit information about periodicity or orthogonal/triclinic box shape is available. The USER-MOLFILE package makes a best effort to guess based on heuristics, but this may not always work perfectly.

Per-atom information from the dump file snapshot is then read from the dump file snapshot. This corresponds to the specified *fields* listed in the *read_dump* command. It is an error to specify a z-dimension field, namely \( z \), \( vz \), or \( iz \), for a 2d simulation.

For dump files in *native* format, each column of per-atom data has a text label listed in the file. A matching label for each field must appear, e.g. the label “\( vy \)” for the field \( vy \). For the \( x \), \( y \), \( z \) fields any of the following labels are considered a match:

\[
\begin{align*}
    x, & \text{ xs, xu, xsu for field } x \\
    y, & \text{ ys, yu, ysu for field } y \\
    z, & \text{ zs, zu, zsu for field } z
\end{align*}
\]

The meaning of \( \text{xs} \) (scaled), \( \text{xu} \) (unwrapped), and \( \text{xsu} \) (scaled and unwrapped) is explained on the *dump* command doc page. These labels are searched for in the list of column labels in the dump file, in order, until a match is found.

The dump file must also contain atom IDs, with a column label of “id”.

If the *add* keyword is specified with a value of *yes* or *keep*, as discussed below, the dump file must contain atom types, with a column label of “type”.

If a column label you want to read from the dump file is not a match to a specified field, the *label* keyword can be used to specify the specific column label from the dump file to associate with that field. An example is if a time-averaged coordinate is written to the dump file via the *fix ave/atom* command. The column will then have a label corresponding to the fix-ID rather than “\( x \)” or “\( xs \)”. The *label* keyword can also be used to specify new column labels for fields *id* and *type*.

For dump files in *xyz* format, only the \( x \), \( y \), and \( z \) fields are supported. The dump file does not store atom IDs, so these are assigned consecutively to the atoms as they appear in the dump file, starting from 1. Thus you should insure that order of atoms is consistent from snapshot to snapshot in the XYZ dump file. See the *dump_modify sort* command if the XYZ dump file was written by LAMMPS.

For dump files in *molfile* format, the \( x \), \( y \), \( z \), \( vx \), \( vy \), and \( vz \) fields can be specified. However, not all molfile formats store velocities, or their respective plugins may not support reading of velocities. The molfile dump files do not store atom IDs, so these are assigned consecutively to the atoms as they appear in the dump file, starting from 1. Thus you should insure that order of atoms are consistent from snapshot to snapshot in the molfile dump file. See the *dump_modify sort* command if the dump file was written by LAMMPS.
The *adios* format supports all fields that the *native* format supports except for the *q* charge field. The list of fields stored in an *adios* .bp file is recorded in the attributes *columns* (array of short strings) and *columnstr* (space-separated single string).

```
$ bpls -la dump.bp column*
  string columns attr = {"id", "type", "x", "y", "z", "vx", "vy", "vz "}
  string columnstr attr = "id type x y z vx vy vz "
```

Information from the dump file snapshot is used to overwrite or replace properties of the current system. There are various options for how this is done, determined by the specified fields and optional keywords.

The timestep of the snapshot becomes the current timestep for the simulation. See the *reset_timestep* command if you wish to change this after the dump snapshot is read.

If the *box* keyword is specified with a *yes* value, then the current simulation box dimensions are replaced by the dump snapshot box dimensions. If the *box* keyword is specified with a *no* value, the current simulation box is unchanged.

If the *purge* keyword is specified with a *yes* value, then all current atoms in the system are deleted before any of the operations invoked by the *replace*, *trim*, or *add* keywords take place.

If the *replace* keyword is specified with a *yes* value, then atoms with IDs that are in both the current system and the dump snapshot have their properties overwritten by field values. If the *replace* keyword is specified with a *no* value, atoms with IDs that are in both the current system and the dump snapshot are not modified.

If the *trim* keyword is specified with a *yes* value, then atoms with IDs that are in the current system but not in the dump snapshot are deleted. These atoms are unaffected if the *trim* keyword is specified with a *no* value.

If the *add* keyword is specified with a *no* value (default), then dump file atoms with IDs that are not in the current system are not added to the system. They are simply ignored.

If a *yes* value is specified, the atoms with new IDs are added to the system but their atom IDs are not preserved. Instead, after all the atoms are added, new IDs are assigned to them in the same manner as is described for the *create_atoms* command. Basically the largest existing atom ID in the system is identified, and all the added atoms are assigned IDs that consecutively follow the largest ID.

If a *keep* value is specified, the atoms with new IDs are added to the system and their atom IDs are preserved. This may lead to non-contiguous IDs for the combined system.

Note that atoms added via the *add* keyword will only have the attributes read from the dump file due to the *field* arguments. For example, if *x* or *y* or *z* or *q* is not specified as a field, a value of 0.0 is used for added atoms. Added atoms must have an atom type, so this value must appear in the dump file.

Any other attributes (e.g. charge or particle diameter for spherical particles) will be set to default values, the same as if the *create_atoms* command were used.

Atom coordinates read from the dump file are first converted into unscaled coordinates, relative to the box dimensions of the snapshot. These coordinates are then be assigned to an existing or new atom in the current simulation. The coordinates will then be remapped to the simulation box, whether it is the original box or the dump snapshot box. If periodic boundary conditions apply, this means the atom will be remapped back into the simulation box if necessary. If shrink-wrap boundary conditions apply, the new coordinates may change the simulation box dimensions. If fixed boundary conditions apply, the atom will be lost if it is outside the simulation box.

For *native* format dump files, the 3 *xyz* image flags for an atom in the dump file are set to the corresponding values appearing in the dump file if the *ix*, *iy*, *iz* fields are specified. If not specified, the image flags for replaced atoms are not changed and image flags for new atoms are set to default values. If coordinates read from the dump file are in unwrapped format (e.g. *xu*) then the image flags for read-in atoms are also set to default values. The remapping
procedure described in the previous paragraph will then change images flags for all atoms (old and new) if periodic boundary conditions are applied to remap an atom back into the simulation box.

**Note:** If you get a warning about inconsistent image flags after reading in a dump snapshot, it means one or more pairs of bonded atoms now have inconsistent image flags. As discussed on the Errors common doc page this may or may not cause problems for subsequent simulations. One way this can happen is if you read image flag fields from the dump file but do not also use the dump file box parameters.

LAMMPS knows how to compute unscaled and remapped coordinates for the snapshot column labels discussed above, e.g. $x$, $xs$, $xu$, $xsu$. If another column label is assigned to the $x$ or $y$ or $z$ field via the *label* keyword, e.g. for coordinates output by the *fix ave/atom* command, then LAMMPS needs to know whether the coordinate information in the dump file is scaled and/or wrapped. This can be set via the *scaled* and *wrapped* keywords. Note that the value of the *scaled* and *wrapped* keywords is ignored for fields $x$ or $y$ or $z$ if the *label* keyword is not used to assign a column label to that field.

The scaled/unscaled and wrapped/unwrapped setting must be identical for any of the $x$, $y$, $z$ fields that are specified. Thus you cannot read $xs$ and $yu$ from the dump file. Also, if the dump file coordinates are scaled and the simulation box is triclinic, then all 3 of the $x$, $y$, $z$ fields must be specified, since they are all needed to generate absolute, unscaled coordinates.

### 17.99.4 Restrictions

To read gzipped dump files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option. See the *Build settings* doc page for details.

The *molfile* dump file formats are part of the USER-MOLFILE package. They are only enabled if LAMMPS was built with that packages. See the *Build package* doc page for more info.

To write and read adios .bp files, you must compile LAMMPS with the *USER-ADIOS* package.

### 17.99.5 Related commands

`dump, dump molfile, dump adios, read_data, read_restart, rerun`

### 17.99.6 Default

The option defaults are box = yes, replace = yes, purge = no, trim = no, add = no, scaled = no, wrapped = yes, and format = native.

### 17.100 read_restart command

#### 17.100.1 Syntax

```
read_restart file flag
```

- `file` = name of binary restart file to read in
- `flag` = remap (optional)
### 17.100.2 Examples

<tr>
<td>read_restart</td>
<td>restart.*.mpiio</td>
</tr>
<tr>
<td>read_restart</td>
<td>poly.*.% remap</td>
</tr>
</tbody>
</table>

### 17.100.3 Description

Read in a previously saved system configuration from a restart file. This allows continuation of a previous run. Details about what information is stored (and not stored) in a restart file is given below. Basically this operation will re-create the simulation box with all its atoms and their attributes as well as some related global settings, at the point in time it was written to the restart file by a previous simulation. The simulation box will be partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors in the current simulation and the settings of the `processors` command. The partitioning can later be changed by the `balance` or `fix balance` commands.

**Note:** Normally, restart files are written by the `restart` or `write_restart` commands so that all atoms in the restart file are inside the simulation box. If this is not the case, the `read_restart` command will print an error that atoms were “lost” when the file is read. This error should be reported to the LAMMPS developers so the invalid writing of the restart file can be fixed. If you still wish to use the restart file, the optional `remap` flag can be appended to the `read_restart` command. This should avoid the error, by explicitly remapping each atom back into the simulation box, updating image flags for the atom appropriately.

Restart files are saved in binary format to enable exact restarts, meaning that the trajectories of a restarted run will precisely match those produced by the original run if it continued on.

Several things can prevent exact restarts due to round-off effects, in which case the trajectories in the 2 runs will slowly diverge. These include running on a different number of processors or changing certain settings such as those set by the `newton` or `processors` commands. LAMMPS will issue a warning in these cases.

Certain fixes will not restart exactly, though they should provide statistically similar results. These include `fix shake` and `fix langevin`.

Certain pair styles will not restart exactly, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities, which are used at half-step values every timestep when forces are computed. When a run restarts, forces are initially evaluated with a full-step velocity, which is different than if the run had continued. These pair styles include `granular pair styles`, `pair dpd`, and `pair lubricate`.

If a restarted run is immediately different than the run which produced the restart file, it could be a LAMMPS bug, so consider reporting it if you think the behavior is a bug.

Because restart files are binary, they may not be portable to other machines. In this case, you can use the `-restart` command-line switch to convert a restart file to a data file.

Similar to how restart files are written (see the `write_restart` and `restart` commands), the restart filename can contain two wild-card characters. If a “*” appears in the filename, the directory is searched for all filenames that match the pattern where “*” is replaced with a timestep value. The file with the largest timestep value is read in. Thus, this effectively means, read the latest restart file. It’s useful if you want your script to continue a run from where it left off. See the `run` command and its “upto” option for how to specify the run command so it does not need to be changed either.

If a “%” character appears in the restart filename, LAMMPS expects a set of multiple files to exist. The `restart` and `write_restart` commands explain how such sets are created. Read_restart will first read a filename where “%” is replaced by “base”. This file tells LAMMPS how many processors created the set and how many files are in it.
Read_restart then reads the additional files. For example, if the restart file was specified as save.% when it was written, then read_restart reads the files save.base, save.0, save.1, ..., save.P-1, where P is the number of processors that created the restart file.

Note that P could be the total number of processors in the previous simulation, or some subset of those processors, if the fileper or nfile options were used when the restart file was written; see the restart and write_restart commands for details. The processors in the current LAMMPS simulation share the work of reading these files; each reads a roughly equal subset of the files. The number of processors which created the set can be different the number of processors in the current LAMMPS simulation. This can be a fast mode of input on parallel machines that support parallel I/O.

A restart file can also be read in parallel as one large binary file via the MPI-IO library, assuming it was also written with MPI-IO. MPI-IO is part of the MPI standard for versions 2.0 and above. Using MPI-IO requires two steps. First, build LAMMPS with its MPIIO package installed, e.g.

```
make yes-mpiio  # installs the MPIIO package
make mpi        # build LAMMPS for your platform
```

Second, use a restart filename which contains “.mpiio”. Note that it does not have to end in “.mpiio”, just contain those characters. Unlike MPI-IO dump files, a particular restart file must be both written and read using MPI-IO.

Here is the list of information included in a restart file, which means these quantities do not need to be re-specified in the input script that reads the restart file, though you can redefine many of these settings after the restart file is read.

- units
- newton bond (see discussion of newton command below)
- atom style and atom_modify settings id, map, sort
- comm style and comm_modify settings mode, cutoff, vel
- timestep
- simulation box size and shape and boundary settings
- atom group definitions
- per-type atom settings such as mass
- per-atom attributes including their group assignments and molecular topology attributes (bonds, angles, etc)
- force field styles (pair, bond, angle, etc)
- force field coefficients (pair, bond, angle, etc) in some cases (see below)
- pair_modify settings, except the compute option
- special_bonds settings

Here is a list of information not stored in a restart file, which means you must re-issue these commands in your input script, after reading the restart file.

- newton pair (see discussion of newton command below)
- fix commands (see below)
- compute commands (see below)
- variable commands
- region commands
- neighbor list criteria including neigh_modify settings
- kspace_style and kspace_modify settings

17.100. read_restart command
• info for thermodynamic, dump, or restart output

The newton command has two settings, one for pairwise interactions, the other for bonded. Both settings are stored in the restart file. For the bond setting, the value in the file will overwrite the current value (at the time the read_restart command is issued) and warn if the two values are not the same and the current value is not the default. For the pair setting, the value in the file will not overwrite the current value (so that you can override the previous run’s value), but a warning is issued if the two values are not the same and the current value is not the default.

Note that some force field styles (pair, bond, angle, etc) do not store their coefficient info in restart files. Typically these are many-body or tabulated potentials which read their parameters from separate files. In these cases you will need to re-specify the pair_coeff, bond_coeff, etc commands in your restart input script. The doc pages for individual force field styles mention if this is the case. This is also true of pair_style hybrid (bond hybrid, angle hybrid, etc) commands; they do not store coefficient info.

As indicated in the above list, the fixes used for a simulation are not stored in the restart file. This means the new input script should specify all fixes it will use. However, note that some fixes store an internal “state” which is written to the restart file. This allows the fix to continue on with its calculations in a restarted simulation. To re-enable such a fix, the fix command in the new input script must be of the same style and use the same fix-ID as was used in the input script that wrote the restart file.

If a match is found, LAMMPS prints a message indicating that the fix is being re-enabled. If no match is found before the first run or minimization is performed by the new script, the “state” information for the saved fix is discarded. At the time the discard occurs, LAMMPS will also print a list of fixes for which the information is being discarded. See the doc pages for individual fixes for info on which ones can be restarted in this manner. Note that fixes which are created internally by other LAMMPS commands (computes, fixes, etc) will have style names which are all-capitalized, and IDs which are generated internally.

Likewise, the computes used for a simulation are not stored in the restart file. This means the new input script should specify all computes it will use. However, some computes create a fix internally to store “state” information that persists from timestep to timestep. An example is the compute msd command which uses a fix to store a reference coordinate for each atom, so that a displacement can be calculated at any later time. If the compute command in the new input script uses the same compute-ID and group-ID as was used in the input script that wrote the restart file, then it will create the same fix in the restarted run. This means the re-created fix will be re-enabled with the stored state information as described in the previous paragraph, so that the compute can continue its calculations in a consistent manner.

Note: There are a handful of commands which can be used before or between runs which may require a system initialization. Examples include the “balance”, “displace_atoms”, “delete_atoms”, “set” (some options), and “velocity” (some options) commands. This is because they can migrate atoms to new processors. Thus they will also discard unused “state” information from fixes. You will know the discard has occurred because a list of discarded fixes will be printed to the screen and log file, as explained above. This means that if you wish to retain that info in a restarted run, you must re-specify the relevant fixes and computes (which create fixes) before those commands are used.

Some pair styles, like the granular pair styles, also use a fix to store “state” information that persists from timestep to timestep. In the case of granular potentials, it is contact information between pairs of touching particles. This info will also be re-enabled in the restart script, assuming you re-use the same granular pair style.

LAMMPS allows bond interactions (angle, etc) to be turned off or deleted in various ways, which can affect how their info is stored in a restart file.

If bonds (angles, etc) have been turned off by the fix shake or delete_bonds command, their info will be written to a restart file as if they are turned on. This means they will need to be turned off again in a new run after the restart file is read.

Bonds that are broken (e.g. by a bond-breaking potential) are written to the restart file as broken bonds with a type of 0. Thus these bonds will still be broken when the restart file is read.
Bonds that have been broken by the `fix bond/break` command have disappeared from the system. No information about these bonds is written to the restart file.

### 17.100.4 Restrictions

To write and read restart files in parallel with MPI-IO, the MPIIO package must be installed.

### 17.100.5 Related commands

`read_data`, `read_dump`, `write_restart`, `restart`

### 17.100.6 Default

none

### 17.101 region command

#### 17.101.1 Syntax

```
region ID style args keyword arg ...
```

- **ID** = user-assigned name for the region
- **style** = `delete` or `block` or `cone` or `cylinder` or `plane` or `prism` or `sphere` or `union` or `intersect`

`delete` = no args

`block` args = `xlo xhi ylo yhi zlo zhi`
  `xlo,xhi,ylo,yhi,zlo,zhi` = bounds of block in all dimensions (distance units)

`cone` args = `dim c1 c2 radlo radhi lo hi`
  `dim` = `x` or `y` or `z` = axis of cone
  `c1,c2` = coords of cone axis in other 2 dimensions (distance units)
  `radlo,radhi` = cone radii at `lo` and `hi` end (distance units)
  `lo,hi` = bounds of cone in `dim` (distance units)

`cylinder` args = `dim c1 c2 radius lo hi`
  `dim` = `x` or `y` or `z` = axis of cylinder
  `c1,c2` = coords of cylinder axis in other 2 dimensions (distance units)
  `radius` = cylinder radius (distance units)
  `c1,c2, and radius can be a variable (see below)
  `lo,hi` = bounds of cylinder in `dim` (distance units)

`plane` args = `px py pz nx ny nz`
  `px,py,pz` = point on the plane (distance units)
  `nx,ny,nz` = direction normal to plane (distance units)

`prism` args = `xlo xhi ylo yhi zlo zhi xy xz yz`
  `xlo,xhi,ylo,yhi,zlo,zhi` = bounds of untitled prism (distance units)
  `xy = distance to tilt y in x direction (distance units)
  `xz = distance to tilt z in x direction (distance units)
  `yz = distance to tilt z in y direction (distance units)

`sphere` args = `x y z radius`
x, y, z = center of sphere (distance units)
radius = radius of sphere (distance units)
x, y, z, and radius can be a variable (see below)
union args = N reg-ID1 reg-ID2 ...
  N = # of regions to follow, must be 2 or greater
  reg-ID1, reg-ID2, ... = IDs of regions to join together
intersect args = N reg-ID1 reg-ID2 ...
  N = # of regions to follow, must be 2 or greater
  reg-ID1, reg-ID2, ... = IDs of regions to intersect

• zero or more keyword/arg pairs may be appended
• keyword = side or units or move or rotate or open
  side value = in or out
    in = the region is inside the specified geometry
    out = the region is outside the specified geometry
  units value = lattice or box
    lattice = the geometry is defined in lattice units
    box = the geometry is defined in simulation box units
  move args = v_x v_y v_z
    v_x, v_y, v_z = equal-style variables for x, y, z displacement of region
    over time
  rotate args = v_theta Px Py Pz Rx Ry Rz
    v_theta = equal-style variable for rotation of region over time (in radians)
    Px, Py, Pz = origin for axis of rotation (distance units)
    Rx, Ry, Rz = axis of rotation vector
  open value = integer from 1-6 corresponding to face index (see below)

• accelerated styles (with same args) = block/kk

17.101.2 Examples

region 1 block -3.0 5.0 INF 10.0 INF INF
region 2 sphere 0.0 0.0 0.0 5 side out
region void cylinder y 2 3 5 -5.0 EDGE units box

region funnel cone z 10 10 2 5 0 10 open 1 units box

17.101.3 Description

This command defines a geometric region of space. Various other commands use regions. For example, the region can be filled with atoms via the create_atoms command. Or a bounding box around the region, can be used to define the simulation box via the create_box command. Or the atoms in the region can be identified as a group via the group command, or deleted via the delete_atoms command. Or the surface of the region can be used as a boundary wall via the fix wall/region command.

Commands which use regions typically test whether an atom’s position is contained in the region or not. For this purpose, coordinates exactly on the region boundary are considered to be interior to the region. This means, for example, for a spherical region, an atom on the sphere surface would be part of the region if the sphere were defined
with the *side* in keyword, but would not be part of the region if it were defined using the *side* out keyword. See more details on the *side* keyword below.

Normally, regions in LAMMPS are “static”, meaning their geometric extent does not change with time. If the *move* or *rotate* keyword is used, as described below, the region becomes “dynamic”, meaning it’s location or orientation changes with time. This may be useful, for example, when thermostating a region, via the compute temp/region command, or when the fix wall/region command uses a region surface as a bounding wall on particle motion, i.e. a rotating container.

The *delete* style removes the named region. Since there is little overhead to defining extra regions, there is normally no need to do this, unless you are defining and discarding large numbers of regions in your input script.

The lo/hi values for *block* or *cone* or *cylinder* or *prism* styles can be specified as EDGE or INF. EDGE means they extend all the way to the global simulation box boundary. Note that this is the current box boundary; if the box changes size during a simulation, the region does not. INF means a large negative or positive number (1.0e20), so it should encompass the simulation box even if it changes size. If a region is defined before the simulation box has been created (via *create_box* or *read_data* or *read_restart* commands), then an EDGE or INF parameter cannot be used. For a *prism* region, a non-zero tilt factor in any pair of dimensions cannot be used if both the lo/hi values in either of those dimensions are INF. E.g. if the xy tilt is non-zero, then xlo and xhi cannot both be INF, nor can ylo and yhi.

**Note:** Regions in LAMMPS do not get wrapped across periodic boundaries, as specified by the *boundary* command. For example, a spherical region that is defined so that it overlaps a periodic boundary is not treated as 2 half-spheres, one on either side of the simulation box.

**Note:** Regions in LAMMPS are always 3d geometric objects, regardless of whether the *dimension* of a simulation is 2d or 3d. Thus when using regions in a 2d simulation, you should be careful to define the region so that its intersection with the 2d x-y plane of the simulation has the 2d geometric extent you want.

For style *cone*, an axis-aligned cone is defined which is like a *cylinder* except that two different radii (one at each end) can be defined. Either of the radii (but not both) can be 0.0.

For style *cone* and *cylinder*, the c1,c2 params are coordinates in the 2 other dimensions besides the cylinder axis dimension. For dim = x, c1/c2 = y/z; for dim = y, c1/c2 = x/z; for dim = z, c1/c2 = x/y. Thus the third example above specifies a cylinder with its axis in the y-direction located at x = 2.0 and z = 3.0, with a radius of 5.0, and extending in the y-direction from -5.0 to the upper box boundary.

For style *plane*, a plane is defined which contain the point (px,py,pz) and has a normal vector (nx,ny,nz). The normal vector does not have to be of unit length. The “inside” of the plane is the half-space in the direction of the normal vector; see the discussion of the *side* option below.

For style *prism*, a parallelepiped is defined (it’s too hard to spell parallelepiped in an input script!). The parallelepiped has its “origin” at (xlo,ylo,zlo) and is defined by 3 edge vectors starting from the origin given by A = (xhi-xlo,0,0); B = (xy,yhi-ylo,0); C = (xz,yz,zhi-zlo). Xy,xz,yz can be 0.0 or positive or negative values and are called “tilt factors” because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped.

A prism region that will be used with the *create_box* command to define a triclinic simulation box must have tilt factors (xy,xz,yz) that do not skew the box more than half the distance of corresponding the parallel box length. For example, if xlo = 2 and xhi = 12, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between -(xhi-xlo)/2 and +(yhi-ylo)/2. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = …, -15, -5, 5, 15, 25, … are all geometrically equivalent.

The *radius* value for style *sphere* and *cylinder* can be specified as an equal-style variable. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each
timestep, and its value used to determine the radius of the region. For style sphere also the x-, y-, and z- coordinate of the center of the sphere and for style cylinder the two center positions c1 and c2 for the location of the cylinder axes can be a variable with the same kind of effect and requirements than for the radius.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent radius or have a time dependent position of the sphere or cylinder region.

See the Howto tricilinc doc page for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

The union style creates a region consisting of the volume of all the listed regions combined. The intersect style creates a region consisting of the volume that is common to all the listed regions.

Note: The union and intersect regions operate by invoking methods from their list of sub-regions. Thus you cannot delete the sub-regions after defining a union or intersect region.

The side keyword determines whether the region is considered to be inside or outside of the specified geometry. Using this keyword in conjunction with union and intersect regions, complex geometries can be built up. For example, if the interior of two spheres were each defined as regions, and a union style with side = out was constructed listing the region-IDs of the 2 spheres, the resulting region would be all the volume in the simulation box that was outside both of the spheres.

The units keyword determines the meaning of the distance units used to define the region for any argument above listed as having distance units. It also affects the scaling of the velocity vector specified with the vel keyword, the amplitude vector specified with the wiggle keyword, and the rotation point specified with the rotate keyword, since they each involve a distance metric.

A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacings which are used as follows:

- For style block, the lattice spacing in dimension x is applied to xlo and xhi, similarly the spacings in dimensions y,z are applied to ylo/yhi and zlo/zh.
- For style cone, the lattice spacing in argument dim is applied to lo and hi. The spacings in the two radial dimensions are applied to c1 and c2. The two cone radii are scaled by the lattice spacing in the dimension corresponding to c1.
- For style cylinder, the lattice spacing in argument dim is applied to lo and hi. The spacings in the two radial dimensions are applied to c1 and c2. The cylinder radius is scaled by the lattice spacing in the dimension corresponding to c1.
- For style plane, the lattice spacing in dimension x is applied to px and nx, similarly the spacings in dimensions y,z are applied to py/ny and pz/nz.
- For style prism, the lattice spacing in dimension x is applied to xlo and xhi, similarly for ylo/yhi and zlo/zh. The lattice spacing in dimension x is applied to xy and xz, and the spacing in dimension y to yz.
- For style sphere, the lattice spacing in dimensions x,y,z are applied to the sphere center x,y,z. The spacing in dimension x is applied to the sphere radius.

If the move or rotate keywords are used, the region is “dynamic”, meaning its location or orientation changes with time. These keywords cannot be used with a union or intersect style region. Instead, the keywords should be used to make the individual sub-regions of the union or intersect region dynamic. Normally, each sub-region should be “dynamic” in the same manner (e.g. rotate around the same point), though this is not a requirement.
The *move* keyword allows one or more *equal-style variables* to be used to specify the x,y,z displacement of the region, typically as a function of time. A variable is specified as v_name, where name is the variable name. Any of the three variables can be specified as NULL, in which case no displacement is calculated in that dimension.

Note that equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a region displacement that change as a function of time or spans consecutive runs in a continuous fashion. For the latter, see the *start* and *stop* keywords of the *run* command and the *elaplong* keyword of *thermo_style custom* for details.

For example, these commands would displace a region from its initial position, in the positive x direction, effectively at a constant velocity:

```
variable dx equal ramp(0,10)
region 2 sphere 10.0 10.0 0.0 5 move v_dx NULL NULL
```

Note that the initial displacement is 0.0, though that is not required.

Either of these variables would “wiggle” the region back and forth in the y direction:

```
variable dy equal swiggle(0,5,100)
variable dysame equal 5*sin(2*PI*elaplong*dt/100)
region 2 sphere 10.0 10.0 0.0 5 move NULL v_dy NULL
```

The *rotate* keyword rotates the region around a rotation axis $R = (Rx,Ry,Rz)$ that goes through a point $P = (Px,Py,Pz)$. The rotation angle is calculated, presumably as a function of time, by a variable specified as v_theta, where theta is the variable name. The variable should generate its result in radians. The direction of rotation for the region around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along $R$, then your fingers wrap around the axis in the direction of rotation.

The *move* and *rotate* keywords can be used together. In this case, the displacement specified by the *move* keyword is applied to the $P$ point of the *rotate* keyword.

The *open* keyword can be used (multiple times) to indicate that one or more faces of the region are ignored for purposes of particle/wall interactions. This keyword is only relevant for regions used by the *fix wall/region* and *fix wall/gran/region* commands. It can be used to create “open” containers where only some of the region faces are walls. For example, a funnel can be created with a *cone* style region that has an open face at the smaller radius for particles to flow out, or at the larger radius for pouring particles into the cone, or both.

Note that using the *open* keyword partly overrides the *side* keyword, since both exterior and interior surfaces of an open region are tested for particle contacts. The exception to this is a *union* or *intersect* region which includes an open sub-region. In that case the *side* keyword is still used to define the union/intersect region volume, and the *open* settings are only applied to the individual sub-regions that use them.

The indices specified as part of the *open* keyword have the following meanings:

For style *block*, indices 1-6 correspond to the xlo, xhi, ylo, yhi, zlo, zhi surfaces of the block. I.e. 1 is the yz plane at x = xlo, 2 is the yz-plane at x = xhi, 3 is the xz plane at y = ylo, 4 is the xz plane at y = yhi, 5 is the xy plane at z = zlo, 6 is the xy plane at z = zhi). In the second-to-last example above, the region is a box open at both xy planes.

For style *prism*, values 1-6 have the same mapping as for style *block*. I.e. in an untilted *prism*, *open* indices correspond to the xlo, xhi, ylo, yhi, zlo, zhi surfaces.

For style *cylinder*, index 1 corresponds to the flat end cap at the low coordinate along the cylinder axis, index 2 corresponds to the high-coordinate flat end cap along the cylinder axis, and index 3 is the curved cylinder surface. For example, a *cylinder* region with *open 1 open 2* keywords will be open at both ends (e.g. a section of pipe), regardless of the cylinder orientation.
For style *cone*, the mapping is the same as for style *cylinder*. Index 1 is the low-coordinate flat end cap, index 2 is the high-coordinate flat end cap, and index 3 is the curved cone surface. In the last example above, a *cone* region is defined along the z-axis that is open at the zlo value (e.g. for use as a funnel).

For all other styles, the *open* keyword is ignored. As indicated above, this includes the *intersect* and *union* regions, though their sub-regions can be defined with the *open* keyword.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

The code using the region (such as a fix or compute) must also be supported by Kokkos or no acceleration will occur. Currently, only *block* style regions are supported by Kokkos.

These accelerated styles are part of the Kokkos package. They are only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

### 17.101.4 Restrictions

A prism cannot be of 0.0 thickness in any dimension; use a small z thickness for 2d simulations. For 2d simulations, the *xz* and *yz* parameters must be 0.0.

### 17.101.5 Related commands

*lattice, create_atoms, delete_atoms, group*

### 17.101.6 Default

The option defaults are *side = in*, *units = lattice*, and no move or rotation.

### 17.102 replicate command

#### 17.102.1 Syntax

```
replicate nx ny nz keyword
```

*nx, ny, nz* = replication factors in each dimension

- *optional keyword = bbox*

  *bbox* = only check atoms in replicas that overlap with a processor's sub-domain
17.102.2 Examples

```
replicate 2 3 2
```

17.102.3 Description

Replicate the current simulation one or more times in each dimension. For example, replication factors of 2,2,2 will create a simulation with 8x as many atoms by doubling the simulation domain in each dimension. A replication factor of 1 in a dimension leaves the simulation domain unchanged. When the new simulation box is created it is also partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors being used and the settings of the `processors` command. The partitioning can later be changed by the `balance` or `fix balance` commands.

All properties of the atoms are replicated, including their velocities, which may or may not be desirable. New atom IDs are assigned to new atoms, as are molecule IDs. Bonds and other topology interactions are created between pairs of new atoms as well as between old and new atoms. This is done by using the image flag for each atom to "unwrap" it out of the periodic box before replicating it.

This means that any molecular bond you specify in the original data file that crosses a periodic boundary should be between two atoms with image flags that differ by 1. This will allow the bond to be unwrapped appropriately.

The optional keyword `bbox` uses a bounding box to only check atoms in replicas that overlap with a processor’s sub-domain when assigning atoms to processors. It typically results in a substantial speedup when using the replicate command on a large number of processors. It does require temporary use of more memory, specifically that each processor can store all atoms in the entire system before it is replicated.

17.102.4 Restrictions

A 2d simulation cannot be replicated in the z dimension.

If a simulation is non-periodic in a dimension, care should be used when replicating it in that dimension, as it may put atoms nearly on top of each other.

Note: You cannot use the replicate command on a system which has a molecule that spans the box and is bonded to itself across a periodic boundary, so that the molecule is effectively a loop. A simple example would be a linear polymer chain that spans the simulation box and bonds back to itself across the periodic boundary. More realistic examples would be a CNT (meant to be an infinitely long CNT) or a graphene sheet or a bulk periodic crystal where there are explicit bonds specified between near neighbors. (Note that this only applies to systems that have permanent bonds as specified in the data file. A CNT that is just atoms modeled with the AIREBO potential has no such permanent bonds, so it can be replicated.) The reason replication does not work with those systems is that the image flag settings described above cannot be made consistent. i.e. it is not possible to define images flags so that when every pair of bonded atoms is unwrapped (using the image flags), they will be close to each other. The only way the replicate command could work in this scenario is for it to break a bond, insert more atoms, and re-connect the loop for the larger simulation box. But it is not clever enough to do this. So you will have to construct a larger version of your molecule as a pre-processing step and input a new data file to LAMMPS.

If the current simulation was read in from a restart file (before a run is performed), there must not be any fix information stored in the file for individual atoms. Similarly, no fixes can be defined at the time the replicate command is used that require vectors of atom information to be stored. This is because the replicate command does not know how to replicate that information for new atoms it creates. To work around this restriction, restart files may be converted into data files and fixes may be undefined via the `unfix` command before and redefined after the replicate command.
17.103 rerun command

17.103.1 Syntax

rerun file1 file2 ... keyword args ...

- file1, file2, ... = dump file(s) to read
- one or more keywords may be appended, keyword dump must appear and be last

  keyword = first or last or every or skip or start or stop or dump
  first args = Nfirst
    Nfirst = dump timestep to start on
  last args = Nlast
    Nlast = dump timestep to stop on
  every args = Nevery
    Nevery = read snapshots matching every this many timesteps
  skip args = Nskip
    Nskip = read one out of every Nskip snapshots
  start args = Nstart
    Nstart = timestep on which pseudo run will start
  stop args = Nstop
    Nstop = timestep to which pseudo run will end
  dump args = same as read_dump command starting with its field arguments

17.103.2 Examples

rerun dump.file dump x y z vx vy vz
rerun dump1.txt dump2.txt first 10000 every 1000 dump x y z
rerun dump.vels dump x y z vx vy vz box yes format molfile lammppstrj
rerun dump.dcd dump x y z box no format molfile dcd
rerun ../run7/dump.file.gz skip 2 dump x y z box yes
rerun dump.bp dump x y z box no format adios
rerun dump.bp dump x y z vx vy vz format adios timeout 10.0
17.103.3 Description

Perform a pseudo simulation run where atom information is read one snapshot at a time from a dump file(s), and energies and forces are computed on the snapshot to produce thermodynamic or other output.

This can be useful in the following kinds of scenarios, after an initial simulation produced the dump file:

- Compute the energy and forces of snapshots using a different potential.
- Calculate one or more diagnostic quantities on the snapshots that were not computed in the initial run. These can also be computed with settings not used in the initial run, e.g. computing an RDF via the compute rdf command with a longer cutoff than was used initially.
- Calculate the portion of per-atom forces resulting from a subset of the potential. E.g. compute only Coulombic forces. This can be done by only defining only a Coulombic pair style in the rerun script. Doing this in the original script would result in different (bad) dynamics.

Conceptually, using the rerun command is like running an input script that has a loop in it (see the next and jump commands). Each iteration of the loop reads one snapshot from the dump file via the read_dump command, sets the timestep to the appropriate value, and then invokes a run command for zero timesteps to simply compute energy and forces, and any other thermodynamic output or diagnostic info you have defined. This computation also invokes any fixes you have defined that apply constraints to the system, such as fix shake or fix indent.

Note that a simulation box must already be defined before using the rerun command. This can be done by the create_box, read_data, or read_restart commands.

Also note that reading per-atom information from dump snapshots is limited to the atom coordinates, velocities and image flags as explained in the read_dump command. Other atom properties, which may be necessary to compute energies and forces, such as atom charge, or bond topology information for a molecular system, are not read from (or even contained in) dump files. Thus this auxiliary information should be defined in the usual way, e.g. in a data file read in by a read_data command, before using the rerun command.

Also note that the frequency of thermodynamic or dump output from the rerun simulation will depend on settings made in the rerun script, the same as for output from any LAMMPS simulation. See further info below as to what that means if the timesteps for snapshots read from dump files do not match the specified output frequency.

If more than one dump file is specified, the dump files are read one after the other. It is assumed that snapshot timesteps will be in ascending order. If a snapshot is encountered that is not in ascending order, it will skip the snapshot until it reads one that is. This allows skipping of a duplicate snapshot (same timestep), e.g. that appeared at the end of one file and beginning of the next. However if you specify a series of dump files in an incorrect order (with respect to the timesteps they contain), you may skip large numbers of snapshots.

Note that the dump files specified as part of the dump keyword can be parallel files, i.e. written as multiple files either per processor and/or per snapshot. If that is the case they will also be read in parallel which can make the rerun command operate dramatically faster for large systems. See the doc page for the read_dump and dump commands which describe how to read and write parallel dump files.

The first, last, every, skip keywords determine which snapshots are read from the dump file(s). Snapshots are skipped until they have a timestamp >= Nfirst. When a snapshot with a timestamp > Nlast is encountered, the rerun command finishes. Note below that the defaults for first and last are to read all snapshots. If the every keyword is set to a value > 0, then only snapshots with timestamps that are a multiple of Nevery are read (the first snapshot is always read). If Nevery = 0, then this criterion is ignored, i.e. every snapshot is read that meets the other criteria. If the skip keyword is used, then after the first snapshot is read, every Nth snapshot is read, where N = Nskip. E.g. if Nskip = 3, then only 1 out of every 3 snapshots is read, assuming the snapshot timestamp is also consistent with the other criteria.

The start and stop keywords do not affect which snapshots are read from the dump file(s). Rather, they have the same meaning that they do for the run command. They only need to be defined if (a) you are using a fix command that changes some value over time, and (b) you want the reference point for elapsed time (from start to stop) to be different...
than the first and last settings. See the doc page for individual fixes to see which ones can be used with the start/stop keywords. Note that if you define neither of the start/stop or first/last keywords, then LAMMPS treats the pseudo run as going from 0 to a huge value (effectively infinity). This means that any quantity that a fix scales as a fraction of elapsed time in the run, will essentially remain at its initial value. Also note that an error will occur if you read a snapshot from the dump file with a timestep value larger than the stop setting you have specified.

The dump keyword is required and must be the last keyword specified. Its arguments are passed internally to the read_dump command. The first argument following the dump keyword should be the field argument of the read_dump command. See the read_dump doc page for details on the various options it allows for extracting information from the dump file snapshots, and for using that information to alter the LAMMPS simulation.

In general, a LAMMPS input script that uses a rerun command can include and perform all the usual operations of an input script that uses the run command. There are a few exceptions and points to consider, as discussed here.

Fixes that perform time integration, such as fix nve or fix npt are not invoked, since no time integration is performed. Fixes that perturb or constrain the forces on atoms will be invoked, just as they would during a normal run. Examples are fix indent and fix langevin. So you should think carefully as to whether that makes sense for the manner in which you are reprocessing the dump snapshots.

If you only want the rerun script to perform an analysis that does not involve pair interactions, such as use compute msd to calculated displacements over time, you do not need to define a pair style, which may also mean neighbor lists will not need to be calculated which saves time. The comm_modify cutoff command can also be used to insure ghost atoms are acquired from far enough away for operations like bond and angle evaluations, if no pair style is being used.

Every time a snapshot is read, the timestep for the simulation is reset, as if the reset_timestep command were used. This command has some restrictions as to what fixes can be defined. See its doc page for details. For example, the fix deposit and fix dt/reset fixes are in this category. They also make no sense to use with a rerun command.

If time-averaging fixes like fix ave/time are used, they are invoked on timesteps that are a function of their Nevery, Nrepeat, and Nfreq settings. As an example, see the fix ave/time doc page for details. You must insure those settings are consistent with the snapshot timestamps that are read from the dump file(s). If an averaging fix is not invoked on a timestep it expects to be, LAMMPS will flag an error.

The various forms of LAMMPS output, as defined by the thermo_style, thermo, dump, and restart commands occur with specified frequency, e.g. every N steps. If the timestep for a dump snapshot is not a multiple of N, then it will be read and processed, but no output will be produced. If you want output for every dump snapshot, you can simply use N=1 for an output frequency, e.g. for thermodynamic output or new dump file output.

17.103.4 Restrictions

To read gzipped dump files, you must compile LAMMPS with the -DLAMMPS_GZIP option. See the Build settings doc page for details.

17.103.5 Related commands

read_dump
17.103.6 Default

The option defaults are first = 0, last = a huge value (effectively infinity), start = same as first, stop = same as last, every = 0, skip = 1;

17.104 reset_atom_ids command

17.104.1 Syntax

```
reset_atom_ids keyword values ...
+ zero or more keyword/value pairs may be appended
  + keyword = "sort"

sort value = yes or no
```

17.104.2 Examples

```
reset_atom_ids
reset_atom_ids sort yes
```

17.104.3 Description

Reset atom IDs for the system, including all the global IDs stored for bond, angle, dihedral, improper topology data. This will create a set of IDs that are numbered contiguously from 1 to N for a N atoms system.

This can be useful to do after performing a “delete_atoms” command for a molecular system. The delete_atoms compress yes option will not perform this operation due to the existence of bond topology. It can also be useful to do after any simulation which has lost atoms, e.g. due to atoms moving outside a simulation box with fixed boundaries (see the “boundary command”), or due to evaporation (see the “fix evaporate” command).

If the sort keyword is used with a setting of yes, then the assignment of new atom IDs will be the same no matter how many processors LAMMPS is running on. This is done by first doing a spatial sort of all the atoms into bins and sorting them within each bin. Because the set of bins is independent of the number of processors, this enables a consistent assignment of new IDs to each atom.

This can be useful to do after using the “create_atoms” command and/or “replicate” command. In general those commands do not guarantee assignment of the same atom ID to the same physical atom when LAMMPS is run on different numbers of processors. Enforcing consistent IDs can be useful for debugging or comparing output from two different runs.

Note that the spatial sort requires communication of atom IDs and coordinates between processors in an all-to-all manner. This is done efficiently in LAMMPS, but it is more expensive than how atom IDs are reset without sorting.

Note that whether sorting or not, the resetting of IDs is not a compression, where gaps in atom IDs are removed by decrementing atom IDs that are larger. Instead the IDs for all atoms are erased, and new IDs are assigned so that the atoms owned by an individual processor have consecutive IDs, as the create_atoms command explains.

Note: If this command is used before a pair style is defined, an error about bond topology atom IDs not being found may result. This is because the cutoff distance for ghost atom communication was not sufficient to find atoms in bonds, angles, etc that are owned by other processors. The comm_modify cutoff command can be used to correct this issue.
Or you can define a pair style before using this command. If you do the former, you should unset the comm_modify
cutoff after using reset_atom_ids so that subsequent communication is not inefficient.

17.104.4 Restrictions

none

17.104.5 Related commands

delete_atoms

17.104.6 Default

By default, sort is no.

17.105 reset_mol_ids command

17.105.1 Syntax

reset_mol_ids group-ID keyword value ...

- group-ID = ID of group of atoms whose molecule IDs will be reset
- zero or more keyword/value pairs may be appended
- keyword = compress or offset or single
  - compress value = yes or no
  - offset value = Noffset >= -1
  - single value = yes or no to treat single atoms (no bonds) as molecules

17.105.2 Examples

reset_mol_ids all
reset_mol_ids all offset 10 single yes
reset_mol_ids solvent compress yes offset 100
reset_mol_ids solvent compress no

17.105.3 Description

Reset molecule IDs for a group of atoms based on current bond connectivity. This will typically create a new set of
molecule IDs for atoms in the group. Only molecule IDs for atoms in the specified group are reset; molecule IDs for
atoms not in the group are not changed.

For purposes of this operation, molecules are identified by the current bond connectivity in the system, which may
or may not be consistent with the current molecule IDs. A molecule in this context is a set of atoms connected to
each other with explicit bonds. The specific algorithm used is the one of compute fragment/atom Once the molecules
are identified and a new molecule ID computed for each, this command will update the current molecule ID for all
atoms in the group with the new molecule ID. Note that if the group excludes atoms within molecules, one (physical) molecule may become two or more (logical) molecules. For example if the group excludes atoms in the middle of a linear chain, then each end of the chain is considered an independent molecule and will be assigned a different molecule ID.

This can be a useful operation to perform after running reactive molecular dynamics run with `fix bond/react`, `fix bond/create`, or `fix bond/break`, all of which can change molecule topologies. It can also be useful after molecules have been deleted with the `delete_atoms` command or after a simulation which has lost molecules, e.g. via the `fix evaporate` command.

The `compress` keyword determines how new molecule IDs are computed. If the setting is `yes` (the default) and there are \( N \) molecules in the group, the new molecule IDs will be a set of \( N \) contiguous values. See the `offset` keyword for details on selecting the range of these values. If the setting is `no`, the molecule ID of every atom in the molecule will be set to the smallest atom ID of any atom in the molecule.

The `single` keyword determines whether single atoms (not bonded to another atom) are treated as one-atom molecules or not, based on the `yes` or `no` setting. If the setting is `no` (the default), their molecule IDs are set to 0. This setting can be important if the new molecule IDs will be used as input to other commands such as `compute chunk/atom molecule` or `fix rigid molecule`.

The `offset` keyword is only used if the `compress` setting is `yes`. Its default value is \( N_{offset} = -1 \). In that case, if the specified group is `all`, then the new compressed molecule IDs will range from 1 to \( N \). If the specified group is not `all` and the largest molecule ID of atoms outside that group is \( M \), then the new compressed molecule IDs will range from \( M+1 \) to \( M+N \), to avoid collision with existing molecule IDs. If an `N_{offset} >= 0` is specified, then the new compressed molecule IDs will range from \( N_{offset}+1 \) to \( N_{offset}+N \). If the group is not `all` there may be collisions with the molecule IDs of other atoms.

**Note:** The same as explained for the `compute fragment/atom` command, molecules are identified using the current bond topology. This will not account for bonds broken by the `bond_style quartic` command because it does not perform a full update of the bond topology data structures within LAMMPS.

### 17.105.4 Restrictions

none

### 17.105.5 Related commands

`reset_atom_ids, fix bond/react, fix bond/create, fix bond/break, fix evaporate, delete_atoms, compute fragment/atom`

### 17.105.6 Default

The default keyword settings are `compress = yes`, `single = no`, and `offset = -1`. 
17.106 reset_timestep command

17.106.1 Syntax

\[\text{reset\_timestep } N\]

- \(N = \) timestep number

17.106.2 Examples

```
reset_timestep 0
reset_timestep 400000
```

17.106.3 Description

Set the timestep counter to the specified value. This command normally comes after the timestep has been set by reading a restart file via the `read_restart` command, or a previous simulation advanced the timestep.

The `read_data` and `create_box` commands set the timestep to 0; the `read_restart` command sets the timestep to the value it had when the restart file was written.

17.106.4 Restrictions

none

This command cannot be used when any fixes are defined that keep track of elapsed time to perform certain kinds of time-dependent operations. Examples are the `fix deposit` and `fix dt/reset` commands. The former adds atoms on specific timesteps. The latter keeps track of accumulated time.

Various fixes use the current timestep to calculate related quantities. If the timestep is reset, this may produce unexpected behavior, but LAMMPS allows the fixes to be defined even if the timestep is reset. For example, commands which thermostat the system, e.g. `fix nvt`, allow you to specify a target temperature which ramps from Tstart to Tstop which may persist over several runs. If you change the timestep, you may induce an instantaneous change in the target temperature.

Resetting the timestep clears flags for `computes` that may have calculated some quantity from a previous run. This means these quantity cannot be accessed by a variable in between runs until a new run is performed. See the `variable` command for more details.

17.106.5 Related commands

`rerun`
17.106.6 Default

none

17.107 restart command

17.107.1 Syntax

restart 0
restart N root keyword value ...
restart N file1 file2 keyword value ...

- N = write a restart file every this many timesteps
- N can be a variable (see below)
- root = filename to which timestep # is appended
- file1,file2 = two full filenames, toggle between them when writing file
- zero or more keyword/value pairs may be appended
- keyword = fileper or nfile
  
  fileper arg = Np
  Np = write one file for every this many processors
  nfile arg = Nf
  Nf = write this many files, one from each of Nf processors

17.107.2 Examples

restart 0
restart 1000 poly.restart
restart 1000 poly.restart.mpiio
restart 1000 restart.%.1 equil
restart 10000 poly.%.1 poly.%.2 nfile 10
restart v_mystep poly.restart

17.107.3 Description

Write out a binary restart file with the current state of the simulation every so many timesteps, in either or both of two modes, as a run proceeds. A value of 0 means do not write out any restart files. The two modes are as follows. If one filename is specified, a series of filenames will be created which include the timestep in the filename. If two filenames are specified, only 2 restart files will be created, with those names. LAMMPS will toggle between the 2 names as it writes successive restart files.

Note that you can specify the restart command twice, once with a single filename and once with two filenames. This would allow you, for example, to write out archival restart files every 100000 steps using a single filename, and more frequent temporary restart files every 1000 steps, using two filenames. Using restart 0 will turn off both modes of output.

Similar to dump files, the restart filename(s) can contain two wild-card characters.
If a “*” appears in the single filename, it is replaced with the current timestep value. This is only recognized when a single filename is used (not when toggling back and forth). Thus, the third example above creates restart files as follows: restart.1000.equil, restart.2000.equil, etc. If a single filename is used with no “*”, then the timestep value is appended. E.g. the second example above creates restart files as follows: poly.restart.1000, poly.restart.2000, etc.

If a “%” character appears in the restart filename(s), then one file is written for each processor and the “%” character is replaced with the processor ID from 0 to P-1. An additional file with the “%” replaced by “base” is also written, which contains global information. For example, the files written on step 1000 for filename restart.% would be restart.base.1000, restart.0.1000, restart.1.1000, ..., restart.P-1.1000. This creates smaller files and can be a fast mode of output and subsequent input on parallel machines that support parallel I/O. The optional fileper and nfile keywords discussed below can alter the number of files written.

The restart file can also be written in parallel as one large binary file via the MPI-IO library, which is part of the MPI standard for versions 2.0 and above. Using MPI-IO requires two steps. First, build LAMMPS with its MPIIO package installed, e.g.

```
make yes-mpiio  # installs the MPIIO package
make mpi        # build LAMMPS for your platform
```

Second, use a restart filename which contains “.mpiio”. Note that it does not have to end in “.mpiio”, just contain those characters. Unlike MPI-IO dump files, a particular restart file must be both written and read using MPI-IO.

Restart files are written on timesteps that are a multiple of N but not on the first timestep of a run or minimization. You can use the write_restart command to write a restart file before a run begins. A restart file is not written on the last timestep of a run unless it is a multiple of N. A restart file is written on the last timestep of a minimization if N > 0 and the minimization converges.

Instead of a numeric value, N can be specified as an equal-style variable, which should be specified as v_name, where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which a restart file will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the stagger() and logfreq() and stride() math functions for equal-style variables, as examples of useful functions to use in this context. Other similar math functions could easily be added as options for equal-style variables.

For example, the following commands will write restart files every step from 1100 to 1200, and could be useful for debugging a simulation where something goes wrong at step 1163:

```
variable s equal stride(1100,1200,1)
restart v_s tmp.restart
```

See the read_restart command for information about what is stored in a restart file.

Restart files can be read by a read_restart command to restart a simulation from a particular state. Because the file is binary (to enable exact restarts), it may not be readable on another machine. In this case, you can use the -r command-line switch to convert a restart file to a data file.

**Note:** Although the purpose of restart files is to enable restarting a simulation from where it left off, not all information about a simulation is stored in the file. For example, the list of fixes that were specified during the initial run is not stored, which means the new input script must specify any fixes you want to use. Even when restart information is stored in the file, as it is for some fixes, commands may need to be re-specified in the new input script, in order to re-use that information. See the read_restart command for information about what is stored in a restart file.

The optional nfile or fileper keywords can be used in conjunction with the “%” wildcard character in the specified restart file name(s). As explained above, the “%” character causes the restart file to be written in pieces, one piece
for each of \( P \) processors. By default \( P = \) the number of processors the simulation is running on. The \textit{nfile} or \textit{fileper} keyword can be used to set \( P \) to a smaller value, which can be more efficient when running on a large number of processors.

The \textit{nfile} keyword sets \( P \) to the specified \( N_f \) value. For example, if \( N_f = 4 \), and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a restart file.

For the \textit{fileper} keyword, the specified value of \( N_p \) means write one file for every \( N_p \) processors. For example, if \( N_p = 4 \), every fourth processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a restart file.

\section*{17.107.4 Restrictions}

To write and read restart files in parallel with MPI-IO, the MPIIO package must be installed.

17.108.3 Description

Run or continue dynamics for a specified number of timesteps.

When the run style is respa, N refers to outer loop (largest) timesteps.

A value of N = 0 is acceptable; only the thermodynamics of the system are computed and printed without taking a timestep.

The upto keyword means to perform a run starting at the current timestep up to the specified timestep. E.g. if the current timestep is 10,000 and “run 100000 upto” is used, then an additional 90,000 timesteps will be run. This can be useful for very long runs on a machine that allocates chunks of time and terminate your job when time is exceeded. If you need to restart your script multiple times (reading in the last restart file), you can keep restarting your script with the same run command until the simulation finally completes.

The start or stop keywords can be used if multiple runs are being performed and you want a fix command that changes some value over time (e.g. temperature) to make the change across the entire set of runs and not just a single run. See the doc page for individual fixes to see which ones can be used with the start/stop keywords.

For example, consider this fix followed by 10 run commands:

```
fix 1 all nvt 200.0 300.0 1.0
run 1000 start 0 stop 10000
run 1000 start 0 stop 10000
...
run 1000 start 0 stop 10000
```

The NVT fix ramps the target temperature from 200.0 to 300.0 during a run. If the run commands did not have the start/stop keywords (just “run 1000”), then the temperature would ramp from 200.0 to 300.0 during the 1000 steps of each run. With the start/stop keywords, the ramping takes place over the 10000 steps of all runs together.

The pre and post keywords can be used to streamline the setup, clean-up, and associated output to the screen that happens before and after a run. This can be useful if you wish to do many short runs in succession (e.g. LAMMPS is being called as a library which is doing other computations between successive short LAMMPS runs).

By default (pre and post = yes), LAMMPS creates neighbor lists, computes forces, and imposes fix constraints before every run. And after every run it gathers and prints timings statistics. If a run is just a continuation of a previous run (i.e. no settings are changed), the initial computation is not necessary; the old neighbor list is still valid as are the forces. So if pre is specified as “no” then the initial setup is skipped, except for printing thermodynamic info. Note that if pre is set to “no” for the very first run LAMMPS performs, then it is overridden, since the initial setup computations must be done.

Note: If your input script changes the system between 2 runs, then the initial setup must be performed to insure the change is recognized by all parts of the code that are affected. Examples are adding a fix or dump or compute, changing a neighbor list parameter, or writing restart file which can migrate atoms between processors. LAMMPS has no easy way to check if this has happened, but it is an error to use the pre no option in this case.
If \textit{post} is specified as “no”, the full timing summary is skipped; only a one-line summary timing is printed.

The \textit{every} keyword provides a means of breaking a LAMMPS run into a series of shorter runs. Optionally, one or more LAMMPS commands (c1, c2, …, cN) will be executed in between the short runs. If used, the \textit{every} keyword must be the last keyword, since it has a variable number of arguments. Each of the trailing arguments is a single LAMMPS command, and each command should be enclosed in quotes, so that the entire command will be treated as a single argument. This will also prevent any variables in the command from being evaluated until it is executed multiple times during the run. Note that if a command itself needs one of its arguments quoted (e.g. the \textit{print} command), then you can use a combination of single and double quotes, as in the example above or below.

The \textit{every} keyword is a means to avoid listing a long series of runs and interleaving commands in your input script. For example, a \textit{print} command could be invoked or a \textit{fix} could be redefined, e.g. to reset a thermostat temperature. Or this could be useful for invoking a command you have added to LAMMPS that wraps some other code (e.g. as a library) to perform a computation periodically during a long LAMMPS run. See the \textit{Modify} doc page for info about how to add new commands to LAMMPS. See the \textit{Howto couple} doc page for ideas about how to couple LAMMPS to other codes.

With the \textit{every} option, N total steps are simulated, in shorter runs of M steps each. After each M-length run, the specified commands are invoked. If only a single command is specified as NULL, then no command is invoked. Thus these lines:

\begin{verbatim}
variable q equal x[100]
run 6000 every 2000 "print 'Coord = $q'"
\end{verbatim}

are the equivalent of:

\begin{verbatim}
variable q equal x[100]
run 2000
print "Coord = $q"
run 2000
print "Coord = $q"
run 2000
print "Coord = $q"
\end{verbatim}

which does 3 runs of 2000 steps and prints the x-coordinate of a particular atom between runs. Note that the variable “$q” will be evaluated afresh each time the print command is executed.

Note that by using the line continuation character “&”, the run every command can be spread across many lines, though it is still a single command:

\begin{verbatim}
run 100000 every 1000 &
"print 'Minimum value = $a'" &
"print 'Maximum value = $b'" &
"print 'Temp = $c'" &
"print 'Press = $d'"
\end{verbatim}

If the \textit{pre} and \textit{post} options are set to “no” when used with the \textit{every} keyword, then the first run will do the full setup and the last run will print the full timing summary, but these operations will be skipped for intermediate runs.

\textbf{Note:} You might wish to specify a command that exits the run by jumping out of the loop, e.g.

\begin{verbatim}
variable t equal temp
run 10000 every 100 "if '$t < 300.0' then 'jump SELF afterrun'"
\end{verbatim}

However, this will not work. The run command simply executes each command one at a time each time it pauses, then continues the run.
Instead, you should use the \texttt{fix halt} command, which has additional options for how to exit the run.

### 17.108.4 Restrictions

When not using the \texttt{upto} keyword, the number of specified timesteps \( N \) must fit in a signed 32-bit integer, so you are limited to slightly more than 2 billion steps \((2^{31})\) in a single run. When using \texttt{upto}, \( N \) can be larger than a signed 32-bit integer, however the difference between \( N \) and the current timestep must still be no larger than \( 2^{31} \) steps.

However, with or without the \texttt{upto} keyword, you can perform successive runs to run a simulation for any number of steps (ok, up to \( 2^{63} \) total steps). I.e. the timestep counter within LAMMPS is a 64-bit signed integer.

### 17.108.5 Related commands

\texttt{minimize, run_style, temper, fix halt}

### 17.108.6 Default

The option defaults are start = the current timestep, stop = current timestep + \( N \), pre = yes, and post = yes.

run_style respa 4 2 2 bond 1 dihedral 2 inner 3 5.0 6.0 outer 4 kspace 4
run_style respa 3 4 2 bond 1 hybrid 2 2 1 kspace 3
```

17.109.3 Description

Choose the style of time integrator used for molecular dynamics simulations performed by LAMMPS.

The `verlet` style is a standard velocity-Verlet integrator.

The `verlet/split` style is also a velocity-Verlet integrator, but it splits the force calculation within each timestep over 2 partitions of processors. See the `-partition command-line switch` for info on how to run LAMMPS with multiple partitions.

Specifically, this style performs all computation except the `kspace_style` portion of the force field on the first partition. This include the `pair style`, `bond style`, `neighbor list building`, `fixes` including time integration, and output. The `kspace_style` portion of the calculation is performed on the second partition.

This is most useful for the PPPM `kspace_style` when its performance on a large number of processors degrades due to the cost of communication in its 3d FFTs. In this scenario, splitting your P total processors into 2 subsets of processors, P1 in the first partition and P2 in the second partition, can enable your simulation to run faster. This is because the long-range forces in PPPM can be calculated at the same time as pair-wise and bonded forces are being calculated, and the FFTs can actually speed up when running on fewer processors.

To use this style, you must define 2 partitions where P1 is a multiple of P2. Typically having P1 be 3x larger than P2 is a good choice. The 3d processor layouts in each partition must overlay in the following sense. If P1 is a Px1 by Py1 by Pz1 grid, and P2 = Px2 by Py2 by Pz2, then Px1 must be an integer multiple of Px2, and similarly for Py1 a multiple of Py2, and Pz1 a multiple of Pz2.

Typically the best way to do this is to let the first partition choose its own optimal layout, then require the second partition’s layout to match the integer multiple constraint. See the `processors` command with its `part` keyword for a way to control this, e.g.
You can also use the `partition` command to explicitly specify the processor layout on each partition. E.g. for 2 partitions of 60 and 15 processors each:

```plaintext
partition yes 1 processors 3 4 5
partition yes 2 processors 3 1 5
```

When you run in 2-partition mode with the `verlet/split` style, the thermodynamic data for the entire simulation will be output to the log and screen file of the first partition, which are `log.lammps.0` and `screen.0` by default; see the `-plog` and `-pscreen` command-line switches to change this. The log and screen file for the second partition will not contain thermodynamic output beyond the first timestep of the run.

See the Speed packages doc page for performance details of the speed-up offered by the `verlet/split` style. One important performance consideration is the assignment of logical processors in the 2 partitions to the physical cores of a parallel machine. The `processors` command has options to support this, and strategies are discussed in Section 5 of the manual.

The `respa` style implements the rRESPA multi-timescale integrator (Tuckerman) with N hierarchical levels, where level 1 is the innermost loop (shortest timestep) and level N is the outermost loop (largest timestep). The loop factor arguments specify what the looping factor is between levels. N1 specifies the number of iterations of level 1 for a single iteration of level 2, N2 is the iterations of level 2 per iteration of level 3, etc. N-1 looping parameters must be specified.

Thus with a 4-level respa setting of “2 2 2” for the 3 loop factors, you could choose to have bond interactions computed 8x per large timestep, angle interactions computed 4x, pair interactions computed 2x, and long-range interactions once per large timestep.

The `timestep` command sets the large timestep for the outermost rRESPA level. Thus if the 3 loop factors are “2 2 2” for 4-level rRESPA, and the outer timestep is set to 4.0 fs, then the inner timestep would be 8x smaller or 0.5 fs. All other LAMMPS commands that specify number of timesteps (e.g. `thermo` for thermo output every N steps, `neigh_modify delay/every` parameters, `dump` every N steps, etc) refer to the outermost timesteps.

The rRESPA keywords enable you to specify at what level of the hierarchy various forces will be computed. If not specified, the defaults are that bond forces are computed at level 1 (innermost loop), angle forces are computed where bond forces are, dihedral forces are computed where angle forces are, improper forces are computed where dihedral forces are, pair forces are computed at the outermost level, and kspace forces are computed where pair forces are. The inner, middle, outer forces have no defaults.

For fixes that support it, the rRESPA level at which a given fix is active, can be selected through the `fix_modify` command.

The `inner` and `middle` keywords take additional arguments for cutoffs that are used by the pairwise force computations. If the 2 cutoffs for `inner` are 5.0 and 6.0, this means that all pairs up to 6.0 apart are computed by the inner force. Those between 5.0 and 6.0 have their force go ramped to 0.0 so the overlap with the next regime (middle or outer) is smooth. The next regime (middle or outer) will compute forces for all pairs from 5.0 outward, with those from 5.0 to 6.0 having their value ramped in an inverse manner.

Note that you can use `inner` and `outer` without using `middle` to split the pairwise computations into two portions instead of three. Unless you are using a very long pairwise cutoff, a 2-way split is often faster than a 3-way split, since it avoids too much duplicate computation of pairwise interactions near the intermediate cutoffs.

Also note that only a few pair potentials support the use of the `inner` and `middle` and `outer` keywords. If not, only the `pair` keyword can be used with that pair style, meaning all pairwise forces are computed at the same rRESPA level. See the doc pages for individual pair styles for details.

Another option for using pair potentials with rRESPA is with the `hybrid` keyword, which requires the use of the `pair_style hybrid` or `hybrid/overlay` command. In this scenario, different sub-styles of the hybrid pair style are
evaluated at different rRESPA levels. This can be useful, for example, to set different timesteps for hybrid coarse-grained/all-atom models. The `hybrid` keyword requires as many level assignments as there are hybrid sub-styles, which assigns each sub-style to a rRESPA level, following their order of definition in the `pair_style` command. Since the `hybrid` keyword operates on pair style computations, it is mutually exclusive with either the `pair` or the `inner/middle/outer` keywords.

When using rRESPA (or for any MD simulation) care must be taken to choose a timestep size(s) that insures the Hamiltonian for the chosen ensemble is conserved. For the constant NVE ensemble, total energy must be conserved. Unfortunately, it is difficult to know a priori how well energy will be conserved, and a fairly long test simulation (~10 ps) is usually necessary in order to verify that no long-term drift in energy occurs with the trial set of parameters.

With that caveat, a few rules-of-thumb may be useful in selecting respa settings. The following applies mostly to biomolecular simulations using the CHARMM or a similar all-atom force field, but the concepts are adaptable to other problems. Without SHAKE, bonds involving hydrogen atoms exhibit high-frequency vibrations and require a timestep on the order of 0.5 fs in order to conserve energy. The relatively inexpensive force computations for the bonds, angles, impropers, and dihedrals can be computed on this innermost 0.5 fs step. The outermost timestep cannot be greater than 4.0 fs without risking energy drift. Smooth switching of forces between the levels of the rRESPA hierarchy is also necessary to avoid drift, and a 1-2 angstrom “healing distance” (the distance between the outer and inner cutoffs) works reasonably well. We thus recommend the following settings for use of the `respa` style without SHAKE in biomolecular simulations:

```
  timestep 4.0
  run_style respa 4 2 2 inner 2 4.5 6.0 middle 3 8.0 10.0 outer 4
```

With these settings, users can expect good energy conservation and roughly a 2.5 fold speedup over the `verlet` style with a 0.5 fs timestep.

If SHAKE is used with the `respa` style, time reversibility is lost, but substantially longer time steps can be achieved. For biomolecular simulations using the CHARMM or similar all-atom force field, bonds involving hydrogen atoms exhibit high frequency vibrations and require a time step on the order of 0.5 fs in order to conserve energy. These high frequency modes also limit the outer time step sizes since the modes are coupled. It is therefore desirable to use SHAKE with respa in order to freeze out these high frequency motions and increase the size of the time steps in the respa hierarchy. The following settings can be used for biomolecular simulations with SHAKE and rRESPA:

```
  fix 2 all shake 0.000001 500 0 m 1.0 a 1
  timestep 4.0
  run_style respa 2 2 inner 1 4.0 5.0 outer 2
```

With these settings, users can expect good energy conservation and roughly a 1.5 fold speedup over the `verlet` style with SHAKE and a 2.0 fs timestep.

For non-biomolecular simulations, the `respa` style can be advantageous if there is a clear separation of time scales - fast and slow modes in the simulation. For example, a system of slowly-moving charged polymer chains could be setup as follows:

```
  timestep 4.0
  run_style respa 2 8
```

This is two-level rRESPA with an 8x difference between the short and long timesteps. The bonds, angles, dihedrals will be computed every 0.5 fs (assuming real units), while the pair and kspace interactions will be computed once every 4 fs. These are the default settings for each kind of interaction, so no additional keywords are necessary.

Even a LJ system can benefit from rRESPA if the interactions are divided by the inner, middle and outer keywords. A 2-fold or more speedup can be obtained while maintaining good energy conservation. In real units, for a pure LJ fluid at liquid density, with a sigma of 3.0 angstroms, and epsilon of 0.1 Kcal/mol, the following settings seem to work well:
The *respa/omp* style is a variant of *respa* adapted for use with pair, bond, angle, dihedral, improper, or kspace styles with an *omp* suffix. It is functionally equivalent to *respa* but performs additional operations required for managing *omp* styles. For more on *omp* styles see the *Speed omp* doc page. Accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

You can specify *respa/omp* explicitly in your input script, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

### 17.109.4 Restrictions

The *verlet/split* style can only be used if LAMMPS was built with the REPLICA package. Correspondingly the *respa/omp* style is available only if the USER-OMP package was included. See the *Build package* doc page for more info.

Whenever using rRESPA, the user should experiment with trade-offs in speed and accuracy for their system, and verify that they are conserving energy to adequate precision.

### 17.109.5 Related commands

*timestep, run*

### 17.109.6 Default

**run_style** *verlet*

For *run_style respa*, the default assignment of interactions to rRESPA levels is as follows:

- bond forces = level 1 (innermost loop)
- angle forces = same level as bond forces
- dihedral forces = same level as angle forces
- improper forces = same level as dihedral forces
- pair forces = level N (outermost level)
- kspace forces = same level as pair forces
- inner, middle, outer forces = no default

17.110 server command

17.110.1 Syntax

server protocol

• protocol = md or mc

17.110.2 Examples

server md

17.110.3 Description

This command starts LAMMPS running in “server” mode, where it receives messages from a separate “client” code and responds by sending a reply message back to the client. The specified protocol determines the format and content of messages LAMMPS expects to receive and how it responds.

The Howto client/server doc page gives an overview of client/server coupling of LAMMPS with another code where one code is the “client” and sends request messages to a “server” code. The server responds to each request with a reply message. This enables the two codes to work in tandem to perform a simulation.

When this command is invoked, LAMMPS will run in server mode in an endless loop, waiting for messages from the client code. The client signals when it is done sending messages to LAMMPS, at which point the loop will exit, and the remainder of the LAMMPS input script will be processed.

The protocol argument defines the format and content of messages that will be exchanged between the two codes. The current options are:

• md = run dynamics with another code
• mc = perform Monte Carlo moves with another code

For protocol md, LAMMPS can be either a client (via the fix client/md command) or server. See the server md doc page for details on the protocol.

For protocol mc, LAMMPS can be the server. See the server mc doc page for details on the protocol.

17.110.4 Restrictions

This command is part of the MESSAGE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

A script that uses this command must also use the message command to setup the messaging protocol with the other client code.

17.111 server mc command

17.111.1 Syntax
server mc

mc = the protocol argument to the server command

17.111.2 Examples

server mc

17.111.3 Description

This command starts LAMMPS running in “server” mode, where it will expect messages from a separate “client” code that match the mc protocol for format and content explained below. For each message LAMMPS receives it will send a message back to the client.

The Howto client/server doc page gives an overview of client/server coupling of LAMMPS with another code where one code is the “client” and sends request messages to a “server” code. The server responds to each request with a reply message. This enables the two codes to work in tandem to perform a simulation.

When this command is invoked, LAMMPS will run in server mode in an endless loop, waiting for messages from the client code. The client signals when it is done sending messages to LAMMPS, at which point the loop will exit, and the remainder of the LAMMPS script will be processed.

The server doc page gives other options for using LAMMPS See an example of how this command is used in examples/COUPLE/lammps_mc/in.server.

When using this command, LAMMPS (as the server code) receives instructions from a Monte Carlo (MC) driver to displace random atoms, compute the energy before and after displacement, and run dynamics to equilibrate the system.

The MC driver performs the random displacements on random atoms, accepts or rejects the move in an MC sense, and orchestrates the MD runs.

The format and content of the exchanged messages are explained here in a conceptual sense. Python-style pseudo code for the library calls to the CSlib is shown, which performs the actual message exchange between the two codes. See the CSlib website doc pages for more details on the actual library syntax. The “cs” object in this pseudo code is a pointer to an instance of the CSlib.

See the src/MESSAGE/server_mc.cpp file for details on how LAMMPS uses these messages. See the examples/COUPLE/lammps_mc/mc.cpp file for an example of how an MC driver code can use these messages.
Define NATOMS=1, EINIT=2, DISPLACE=3, ACCEPT=4, RUN=5.

**Client sends one of these kinds of message:**

<table>
<thead>
<tr>
<th>Message ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

17.112 server md command

17.112.1 Syntax

server md

md = the protocol argument to the server command

17.112.2 Examples

server md

17.112.3 Description

This command starts LAMMPS running in “server” mode, where it will expect messages from a separate “client” code that match the md protocol for format and content explained below. For each message LAMMPS receives it will send a message back to the client.

The Howto client/server doc page gives an overview of client/server coupling of LAMMPS with another code where one code is the “client” and sends request messages to a “server” code. The server responds to each request with a reply message. This enables the two codes to work in tandem to perform a simulation.

When this command is invoked, LAMMPS will run in server mode in an endless loop, waiting for messages from the client code. The client signals when it is done sending messages to LAMMPS, at which point the loop will exit, and the remainder of the LAMMPS script will be processed.

The server doc page gives other options for using LAMMPS in server mode. See an example of how this command is used in examples/message/in.message.server.

When using this command, LAMMPS (as the server code) receives the current coordinates of all particles from the client code each timestep, computes their interaction, and returns the energy, forces, and pressure for the interacting particles to the client code, so it can complete the timestep. This command could also be used with a client code that performs energy minimization, using the server to compute forces and energy each iteration of its minimizer.

When using the fix client/md command, LAMMPS (as the client code) does the timestepping and receives needed energy, forces, and pressure values from the server code.

The format and content of the exchanged messages are explained here in a conceptual sense. Python-style pseudo code for the library calls to the CSlib is shown, which performs the actual message exchange between the two codes. See the CSlib website doc pages for more details on the actual library syntax. The “cs” object in this pseudo code is a pointer to an instance of the CSlib.

See the src/MESSAGE/server_md.cpp and src/MESSAGE/fix_client_md.cpp files for details on how LAMMPS uses these messages. See the examples/COUPLE/lammps_vasp/vasp_wrap.py or examples/COUPLE/lammps_nwchem/nwchem_wrap.py files for examples of how a quantum code (VASP or NWChem) can use these messages.

The following pseudo-code uses these values, defined as enums.
Define:

```
SETUP=1, STEP=2
DIM=1, PERIODICITY=2, ORIGIN=3, BOX=4, NATOMS=5, NTYPES=6, TYPES=7, COORDS=8, UNITS=9,
     CHARGE=10
FORCES=1, ENERGY=2, PRESSURE=3, ERROR=4
```

Client sends 2 kinds of messages:

# required fields: DIM, PERIODICITY, ORIGIN, BOX, NATOMS, NTYPES, TYPES, COORDS
# optional fields: UNITS, CHARGE

```c
cs->send(SETUP,nfields) # msgID with nfields
cs->pack_int(DIM,dim) # dimension (2,3) of simulation
cs->pack(PERIODICITY,3,xyz) # periodicity flags in 3 dims
cs->pack(ORIGIN,3,origin) # lower-left corner of simulation box
cs->pack(BOX,9,box) # 3 edge vectors of simulation box
cs->pack_int(NATOMS,natoms) # total number of atoms
cs->pack_int(NTYPES,ntypes) # number of atom types
cs->pack(TYPES,natoms,type) # vector of per-atom types
cs->pack(COORDS,3*natoms,x) # vector of 3N atom coords
```

# required fields: COORDS
# optional fields: ORIGIN, BOX

```c
cs->send(STEP,nfields) # msgID with nfields
cs->pack(COORDS,3*natoms,x) # vector of 3N atom coords
cs->pack(ORIGIN,3,origin) # lower-left corner of simulation box
cs->pack(BOX,9,box) # 3 edge vectors of simulation box
```

Server replies to either kind of message:

# required fields: FORCES, ENERGY, PRESSURE
# optional fields: ERROR

```c
cs->send(msgID,nfields) # msgID with nfields
cs->pack(FORCES,3*Natoms,f) # vector of 3N forces on atoms
cs->pack(ENERGY,1,poteng) # total potential energy of system
```

The units for various quantities that are sent and received via messages are defined for atomic-scale simulations in the table below. The client and server codes (including LAMMPS) can use internal units different than these (e.g. real units in LAMMPS), so long as they convert to these units for messaging.

- **COORDS, ORIGIN, BOX** = Angstroms
- **CHARGE** = multiple of electron charge (1.0 is a proton)
- **ENERGY** = eV
- **FORCES** = eV/Angstrom
- **PRESSURE** = bars
Note that these are metal units in LAMMPS.

If you wish to run LAMMPS in another its non-atomic units, e.g. lj units, then the client and server should exchange a UNITS message as indicated above, and both the client and server should agree on the units for the data they exchange.

17.112.4 Restrictions

This command is part of the MESSAGE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

value can be an atom-style variable (see below)

dipole values = x y z
x, y, z = orientation of dipole moment vector
any of x, y, z can be an atom-style variable (see below)

dipole/random value = seed Dlen
seed = random # seed (positive integer) for dipole moment orientations
Dlen = magnitude of dipole moment (dipole units)

spin values = g x y z
g = magnitude of magnetic spin vector (in Bohr magneton's unit)

x, y, z = orientation of magnetic spin vector
any of x, y, z can be an atom-style variable (see below)

spin/random value = seed Dlen
seed = random # seed (positive integer) for magnetic spin orientations
Dlen = magnitude of magnetic spin vector (in Bohr magneton's unit)

quat values = a b c theta
a, b, c = unit vector to rotate particle around via right-hand rule
theta = rotation angle (degrees)

any of a, b, c, theta can be an atom-style variable (see below)

quat/random value = seed
seed = random # seed (positive integer) for quaternion orientations

shape value = Sx Sy Sz
Sx, Sy, Sz = 3 diameters of ellipsoid (distance units)

length value = len
len = length of line segment (distance units)
len can be an atom-style variable (see below)

tri value = side
side = side length of equilateral triangle (distance units)
side can be an atom-style variable (see below)

theta value = angle (degrees)
angle = orientation of line segment with respect to x-axis
angle can be an atom-style variable (see below)

theta/random value = seed
seed = random # seed (positive integer) for line segment orientations

angmom values = Lx Ly Lz
Lx, Ly, Lz = components of angular momentum vector (distance-mass-velocity units)
any of Lx, Ly, Lz can be an atom-style variable (see below)

omega values = Wx Wy Wz
Wx, Wy, Wz = components of angular velocity vector (radians/time units)
any of Wx, Wy, Wz can be an atom-style variable (see below)

mass value = per-atom mass (mass units)
value can be an atom-style variable (see below)

density value = particle density for a sphere or ellipsoid (mass/distance^3 units),
or for a triangle (mass/distance^2 units) or line

17.113. set command 835

LAMMPS Documentation
(mass/distance units) particle
density/disc value = particle density for a 2d disc or ellipse (mass/
distance^2 units)
 volume value = particle volume for Peridynamic particle (distance^3 units)
 image nx, ny, nz = which periodic image of the simulation box the atom is in
 any of nx, ny, nz can be an atom-style variable (see below)
bond value = bond type for all bonds between selected atoms
 angle value = angle type for all angles between selected atoms
dihedral value = dihedral type for all dihedrals between selected atoms
 improper value = improper type for all impropers between selected atoms
 sph/e value = energy of SPH particles (need units)
 sph/cv value = heat capacity of SPH particles (need units)
 sph/rho value = density of SPH particles (need units)
 smd/contact/radius = radius for short range interactions, i.e. contact and friction
 value can be an atom-style variable (see below)
 smd/mass/density = set particle mass based on volume by providing a mass/density
 value can be an atom-style variable (see below)
 dpd/theta value = internal temperature of DPD particles (temperature units)
 value can be an atom-style variable (see below)
 edpd/temp value = temperature of eDPD particles (temperature units)
 value can be an atom-style variable (see below)
 edpd/cv value = volumetric heat capacity of eDPD particles (energy/temperature/volume units)
 value can be an atom-style variable (see below)
 cc values = index cc
 index = index of a chemical species (1 to Nspecies)
 cc = chemical concentration of tDPD particles for a species (mole/volume units)
i_name value = value for custom integer vector with name
d_name value = value for custom floating-point vector with name

```

(continues on next page)
17.113.3 Description

Set one or more properties of one or more atoms. Since atom properties are initially assigned by the `read_data`, `read_restart` or `create_atoms` commands, this command changes those assignments. This can be useful for overriding the default values assigned by the `create_atoms` command (e.g. charge = 0.0). It can be useful for altering pairwise and molecular force interactions, since force-field coefficients are defined in terms of types. It can be used to change the labeling of atoms by atom type or molecule ID when they are output in `dump` files. It can also be useful for debugging purposes; i.e. positioning an atom at a precise location to compute subsequent forces or energy.

Note that the `style` and `ID` arguments determine which atoms have their properties reset. The remaining keywords specify which properties to reset and what the new values are. Some strings like `type` or `mol` can be used as a style and/or a keyword.

This section describes how to select which atoms to change the properties of, via the `style` and `ID` arguments.

The style `atom` selects all the atoms in a range of atom IDs. The style `type` selects all the atoms in a range of types. The style `mol` selects all the atoms in a range of molecule IDs.

In each of the range cases, the range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form “*” or “*n” or “n*” or “m*n”. For example, for the style `type`, if \( N \) = the number of atom types, then an asterisk with no numeric values means all types from 1 to \( N \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( N \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive). For all the styles except `mol`, the lowest value for the wildcard is 1; for `mol` it is 0.

The style `group` selects all the atoms in the specified group. The style `region` selects all the atoms in the specified geometric region. See the `group` and `region` commands for details of how to specify a group or region.

This section describes the keyword options for which properties to change, for the selected atoms.

Note that except where explicitly prohibited below, all of the keywords allow an atom-style or atomfile-style variable to be used as the specified value(s). If the value is a variable, it should be specified as `v_name`, where name is the variable name. In this case, the variable will be evaluated, and its resulting per-atom value used to determine the value assigned to each selected atom. Note that the per-atom value from the variable will be ignored for atoms that are not selected via the `style` and `ID` settings explained above. A simple way to use per-atom values from the variable to reset a property for all atoms is to use style `atom` with `ID = "*"`; this selects all atom IDs.

Atom-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. They can also include per-atom values, such as atom coordinates. Thus it is easy to specify a time-dependent or spatially-dependent set of per-atom values. As explained on the `variable` doc page, atomfile-style variables can be used in place of atom-style variables, and thus as arguments to the set command. Atomfile-style variables read their per-atoms values from a file.

Note: Atom-style and atomfile-style variables return floating point per-atom values. If the values are assigned to an integer variable, such as the molecule ID, then the floating point value is truncated to its integer portion, e.g. a value of 2.6 would become 2.

Keyword `type` sets the atom type for all selected atoms. The specified value must be from 1 to `ntypes`, where `ntypes` was set by the `create_box` command or the `atom types` field in the header of the data file read by the `read_data` command.
Keyword type/fraction sets the atom type for a fraction of the selected atoms. The actual number of atoms changed is not guaranteed to be exactly the specified fraction (0 <= fraction <= 1), but should be statistically close. Random numbers are used in such a way that a particular atom is changed or not changed, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keywords type/ratio and type/subset also set the atom type for a fraction of the selected atoms. The actual number of atoms changed will be exactly the requested number. For type/ratio the specified fraction (0 <= fraction <= 1) determines the number. For type/subset, the specified Nsubset is the number. An iterative algorithm is used which insures the correct number of atoms are selected, in a perfectly random fashion. Which atoms are selected will change with the number of processors used. These keywords do not allow use of an atom-style variable.

Keyword mol sets the molecule ID for all selected atoms. The atom style being used must support the use of molecule IDs.

Keywords x, y, z, and charge set the coordinates or charge of all selected atoms. For charge, the atom style being used must support the use of atomic charge. Keywords vx, vy, and vz set the velocities of all selected atoms.

Keyword dipole uses the specified x,y,z values as components of a vector to set as the orientation of the dipole moment vectors of the selected atoms. The magnitude of the dipole moment is set by the length of this orientation vector.

Keyword dipole/random randomizes the orientation of the dipole moment vectors for the selected atoms and sets the magnitude of each to the specified Dlen value. For 2d systems, the z component of the orientation is set to 0.0. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keyword spin uses the specified g value to set the magnitude of the magnetic spin vectors, and the x,y,z values as components of a vector to set as the orientation of the magnetic spin vectors of the selected atoms.

Keyword spin/random randomizes the orientation of the magnetic spin vectors for the selected atoms and sets the magnitude of each to the specified Dlen value.

Keyword quat uses the specified values to create a quaternion (4-vector) that represents the orientation of the selected atoms. The particles must define a quaternion for their orientation (e.g. ellipsoids, triangles, body particles) as defined by the atom_style command. Note that particles defined by atom_style ellipsoid have 3 shape parameters. The 3 values must be non-zero for each particle set by this command. They are used to specify the aspect ratios of an ellipsoidal particle, which is oriented by default with its x-axis along the simulation box’s x-axis, and similarly for y and z. If this body is rotated (via the right-hand rule) by an angle theta around a unit rotation vector (a,b,c), then the quaternion that represents its new orientation is given by (cos(theta/2), a*sin(theta/2), b*sin(theta/2), c*sin(theta/2)). The theta and a,b,c values are the arguments to the quat keyword. LAMMPS normalizes the quaternion in case (a,b,c) was not specified as a unit vector. For 2d systems, the a,b,c values are ignored, since a rotation vector of (0,0,1) is the only valid choice.

Keyword quat/random randomizes the orientation of the quaternion for the selected atoms. The particles must define a quaternion for their orientation (e.g. ellipsoids, triangles, body particles) as defined by the atom_style command. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. For 2d systems, only orientations in the xy plane are generated. As with keyword quat, for ellipsoidal particles, the 3 shape values must be non-zero for each particle set by this command. This keyword does not allow use of an atom-style variable.

Keyword diameter sets the size of the selected atoms. The particles must be finite-size spheres as defined by the atom_style sphere command. The diameter of a particle can be set to 0.0, which means they will be treated as point particles. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the read_data command.

Keyword shape sets the size and shape of the selected atoms. The particles must be ellipsoids as defined by the atom_style ellipsoid command. The Sx, Sy, Sz settings are the 3 diameters of the ellipsoid in each direction. All 3 can be set to the same value, which means the ellipsoid is effectively a sphere. They can also all be set to 0.0 which means the particle will be treated as a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the read_data command.
Keyword **length** sets the length of selected atoms. The particles must be line segments as defined by the **atom_style line** command. If the specified value is non-zero the line segment is (re)set to a length = the specified value, centered around the particle position, with an orientation along the x-axis. If the specified value is 0.0, the particle will become a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the **read_data** command.

Keyword **tri** sets the size of selected atoms. The particles must be triangles as defined by the **atom_style tri** command. If the specified value is non-zero the triangle is (re)set to be an equilateral triangle in the xy plane with side length = the specified value, with a centroid at the particle position, with its base parallel to the x axis, and the y-axis running from the center of the base to the top point of the triangle. If the specified value is 0.0, the particle will become a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the **read_data** command.

Keyword **theta** sets the orientation of selected atoms. The particles must be line segments as defined by the **atom_style line** command. The specified value is used to set the orientation angle of the line segments with respect to the x-axis.

Keyword **theta/random** randomizes the orientation of theta for the selected atoms. The particles must be line segments as defined by the **atom_style line** command. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keyword **angmom** sets the angular momentum of selected atoms. The particles must be ellipsoids as defined by the **atom_style ellipsoid** command or triangles as defined by the **atom_style tri** command. The angular momentum vector of the particles is set to the 3 specified components.

Keyword **omega** sets the angular velocity of selected atoms. The particles must be spheres as defined by the **atom_style sphere** command. The angular velocity vector of the particles is set to the 3 specified components.

Keyword **mass** sets the mass of all selected particles. The particles must have a per-atom mass attribute, as defined by the **atom_style** command. See the “mass” command for how to set mass values on a per-type basis.

Keyword **density** or **density/disc** also sets the mass of all selected particles, but in a different way. The particles must have a per-atom mass attribute, as defined by the **atom_style** command. If the atom has a radius attribute (see **atom_style sphere**) and its radius is non-zero, its mass is set from the density and particle volume for 3d systems (the input density is assumed to be in mass/distance^3 units). For 2d, the default is for LAMMPS to model particles with a radius attribute as spheres. However, if the **density/disc** keyword is used, then they can be modeled as 2d discs (circles). Their mass is set from the density and particle area (the input density is assumed to be in mass/distance^2 units).

If the atom has a shape attribute (see **atom_style ellipsoid**) and its 3 shape parameters are non-zero, then its mass is set from the density and particle volume (the input density is assumed to be in mass/distance^3 units). The **density/disc** keyword has no effect; it does not (yet) treat 3d ellipsoids as 2d ellipses.

If the atom has a length attribute (see **atom_style line**) and its length is non-zero, then its mass is set from the density and line segment length (the input density is assumed to be in mass/distance units). If the atom has an area attribute (see **atom_style tri**) and its area is non-zero, then its mass is set from the density and triangle area (the input density is assumed to be in mass/distance^2 units).

If none of these cases are valid, then the mass is set to the density value directly (the input density is assumed to be in mass units).

Keyword **volume** sets the volume of all selected particles. Currently, only the **atom_style peri** command defines particles with a volume attribute. Note that this command does not adjust the particle mass.

Keyword **image** sets which image of the simulation box the atom is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation. The flags can be output with atom snapshots via the **dump** command. If a value of NULL is specified for any of nx,ny,nz, then the current image value for that dimension is unchanged. For non-periodic dimensions only a value of 0 can be specified. This command can be useful after a system has been equilibrated and atoms have
diffused one or more box lengths in various directions. This command can then reset the image values for atoms so that they are effectively inside the simulation box, e.g. if a diffusion coefficient is about to be measured via the compute msd command. Care should be taken not to reset the image flags of two atoms in a bond to the same value if the bond straddles a periodic boundary (rather they should be different by +/- 1). This will not affect the dynamics of a simulation, but may mess up analysis of the trajectories if a LAMMPS diagnostic or your own analysis relies on the image flags to unwrap a molecule which straddles the periodic box.

Keywords `bond`, `angle`, `dihedral`, and `improper`, set the bond type (angle type, etc) of all bonds (angles, etc) of selected atoms to the specified value from 1 to nbondtypes (nangletypes, etc). All atoms in a particular bond (angle, etc) must be selected atoms in order for the change to be made. The value of nbondtype (nangletypes, etc) was set by the `bond types` (angle types, etc) field in the header of the data file read by the `read_data` command. These keywords do not allow use of an atom-style variable.

Keywords `sph/e`, `sph/cv`, and `sph/rho` set the energy, heat capacity, and density of smoothed particle hydrodynamics (SPH) particles. See this PDF guide to using SPH in LAMMPS.

Keyword `smd/mass/density` sets the mass of all selected particles, but it is only applicable to the Smooth Mach Dynamics package USER-SMD. It assumes that the particle volume has already been correctly set and calculates particle mass from the provided mass density value.

Keyword `smd/contact/radius` only applies to simulations with the Smooth Mach Dynamics package USER-SMD. It sets an interaction radius for computing short-range interactions, e.g. repulsive forces to prevent different individual physical bodies from penetrating each other. Note that the SPH smoothing kernel diameter used for computing long range, nonlocal interactions, is set using the `diameter` keyword.

Keyword `dpd/theta` sets the internal temperature of a DPD particle as defined by the USER-DPD package. If the specified value is a number it must be >= 0.0. If the specified value is NULL, then the kinetic temperature $T_{kin}$ of each particle is computed as $3/2 \times k \times T_{kin} = KE = \frac{1}{2} m \times v^2 = \frac{1}{2} m \times (v_x^2+v_y^2+v_z^2)$. Each particle’s internal temperature is set to $T_{kin}$. If the specified value is an atom-style variable, then the variable is evaluated for each particle. If a value >= 0.0, the internal temperature is set to that value. If it is < 0.0, the computation of $T_{kin}$ is performed and the internal temperature is set to that value.

Keywords `edpd/temp` and `edpd/cv` set the temperature and volumetric heat capacity of an eDPD particle as defined by the USER-MESODPD package. Currently, only `atom_style edpd` defines particles with these attributes. The values for the temperature and heat capacity must be positive.

Keyword `cc` sets the chemical concentration of a tDPD particle for a specified species as defined by the USER-MESODPD package. Currently, only `atom_style tdpd` defines particles with this attribute. An integer for “index” selects a chemical species (1 to Nspecies) where Nspecies is set by the `atom_style` command. The value for the chemical concentration must be >= 0.0.

Keywords `i_name` and `d_name` refer to custom integer and floating-point properties that have been added to each atom via the `fix property/atom` command. When that command is used specific names are given to each attribute which are what is specified as the “name” portion of `i_name` or `d_name`.

17.113.4 Restrictions

You cannot set an atom attribute (e.g. `mol` or `q` or `volume`) if the `atom_style` does not have that attribute.

This command requires inter-processor communication to coordinate the setting of bond types (angle types, etc). This means that your system must be ready to perform a simulation before using one of these keywords (force fields set, atom mass set, etc). This is not necessary for other keywords.

Using the `region` style with the bond (angle, etc) keywords can give unpredictable results if there are bonds (angles, etc) that straddle periodic boundaries. This is because the region may only extend up to the boundary and partner atoms in the bond (angle, etc) may have coordinates outside the simulation box if they are ghost atoms.

17.114 shell command

17.114.1 Syntax

shell command args

- command = cd or mkdir or mv or rm or rmdir or putenv or arbitrary command

  cd arg = dir
  dir = directory to change to

  mkdir args = dir1 dir2 ...
  dir1,dir2 = one or more directories to create

  mv args = old new
  old = old filename
  new = new filename

  rm args = file1 file2 ...
  file1,file2 = one or more filenames to delete

  rmdir args = dir1 dir2 ...
  dir1,dir2 = one or more directories to delete

  putenv args = var1=value1 var2=value2
  var=value = one of more definitions of environment variables

  anything else is passed as a command to the shell for direct execution

17.114.2 Examples

```
shell cd sub1
shell cd..
shell mkdir tmp1 tmp2 tmp3
shell rmdir tmp1
shell mv log.lammps hold/log.1
shell rm TMP/file1 TMP/file2
shell putenv LAMMPS_POTENTIALS=../../potentials
shell my_setup file1 10 file2
shell my_post_process 100 dump.out
```
17.114.3 Description

Execute a shell command. A few simple file-based shell commands are supported directly, in Unix-style syntax. Any command not listed above is passed as-is to the C-library system() call, which invokes the command in a shell.

This is means to invoke other commands from your input script. For example, you can move files around in preparation for the next section of the input script. Or you can run a program that pre-processes data for input into LAMMPS. Or you can run a program that post-processes LAMMPS output data.

With the exception of `cd`, all commands, including ones invoked via a system() call, are executed by only a single processor, so that files/directories are not being manipulated by multiple processors.

The `cd` command executes the Unix “cd” command to change the working directory. All subsequent LAMMPS commands that read/write files will use the new directory. All processors execute this command.

The `mkdir` command executes the Unix “mkdir” command to create one or more directories.

The `mv` command executes the Unix “mv” command to rename a file and/or move it to a new directory.

The `rm` command executes the Unix “rm” command to remove one or more files.

The `rmdir` command executes the Unix “rmdir” command to remove one or more directories. A directory must be empty to be successfully removed.

The `putenv` command defines or updates an environment variable directly. Since this command does not pass through the shell, no shell variable expansion or globbing is performed, only the usual substitution for LAMMPS variables defined with the `variable` command is performed. The resulting string is then used literally.

Any other command is passed as-is to the shell along with its arguments as one string, invoked by the C-library system() call. For example, these lines in your input script:

```
variable n equal 10
variable foo string file2
shell my_setup file1 $n ${foo[]}
```

would be the same as invoking

```
$ my_setup file1 10 file2
```

from a command-line prompt. The executable program “my_setup” is run with 3 arguments: file1 10 file2.

17.114.4 Restrictions

LAMMPS does not detect errors or print warnings when any of these commands execute. E.g. if the specified directory does not exist, executing the `cd` command will silently do nothing.

special_bonds lj/coul 0.0 0.0 0.5 angle yes dihedral yes
special_bonds lj 0.0 0.0 0.5 coul 0.0 0.0 0.0 dihedral yes
```

17.115.3 Description

Set weighting coefficients for pairwise energy and force contributions between pairs of atoms that are also permanently bonded to each other, either directly or via one or two intermediate bonds. These weighting factors are used by nearly all pair styles in LAMMPS that compute simple pairwise interactions. Permanent bonds between atoms are specified by defining the bond topology in the data file read by the read_data command. Typically a bond_style command is also used to define a bond potential. The rationale for using these weighting factors is that the interaction between a pair of bonded atoms is all (or mostly) specified by the bond, angle, dihedral potentials, and thus the non-bonded Lennard-Jones or Coulombic interaction between the pair of atoms should be excluded (or reduced by a weighting factor).

Note: These weighting factors are NOT used by pair styles that compute many-body interactions, since the “bonds” that result from such interactions are not permanent, but are created and broken dynamically as atom conformations change. Examples of pair styles in this category are EAM, MEAM, Stillinger-Weber, Tersoff, COMB, AIREBO, and
ReaxFF. In fact, it generally makes no sense to define permanent bonds between atoms that interact via these potentials, though such bonds may exist elsewhere in your system, e.g. when using the \texttt{pair\_style hybrid} command. Thus LAMMPS ignores special\_bonds settings when many-body potentials are calculated. Please note, that the existence of explicit bonds for atoms that are described by a many-body potential will alter the neighbor list and thus can render the computation of those interactions invalid, since those pairs are not only used to determine direct pairwise interactions but also neighbors of neighbors and more. The recommended course of action is to remove such bonds, or - if that is not possible - use a special bonds setting of 1.0 1.0 1.0.

\textbf{Note:} Unlike some commands in LAMMPS, you cannot use this command multiple times in an incremental fashion: e.g. to first set the LJ settings and then the Coulombic ones. Each time you use this command it sets all the coefficients to default values and only overrides the one you specify, so you should set all the options you need each time you use it. See more details at the bottom of this page.

The Coulomb factors are applied to any Coulomb (charge interaction) term that the potential calculates. The LJ factors are applied to the remaining terms that the potential calculates, whether they represent LJ interactions or not. The weighting factors are a scaling pre-factor on the energy and force between the pair of atoms. A value of 1.0 means include the full interaction; a value of 0.0 means exclude it completely.

The first of the 3 coefficients (LJ or Coulombic) is the weighting factor on 1-2 atom pairs, which are pairs of atoms directly bonded to each other. The second coefficient is the weighting factor on 1-3 atom pairs which are those separated by 2 bonds (e.g. the two H atoms in a water molecule). The third coefficient is the weighting factor on 1-4 atom pairs which are those separated by 3 bonds (e.g. the first and fourth atoms in a dihedral interaction). Thus if the 1-2 coefficient is set to 0.0, then the pairwise interaction is effectively turned off for all pairs of atoms bonded to each other. If it is set to 1.0, then that interaction will be at full strength.

\textbf{Note:} For purposes of computing weighted pairwise interactions, 1-3 and 1-4 interactions are not defined from the list of angles or dihedrals used by the simulation. Rather, they are inferred topologically from the set of bonds specified when the simulation is defined from a data or restart file (see \texttt{read\_data} or \texttt{read\_restart} commands). Thus the set of 1-2,1-3,1-4 interactions that the weights apply to is the same whether angle and dihedral potentials are computed or not, and remains the same even if bonds are constrained, or turned off, or removed during a simulation.

The two exceptions to this rule are (a) if the \texttt{angle} or \texttt{dihedral} keywords are set to \texttt{yes} (see below), or (b) if the \texttt{delete\_bonds} command is used with the \texttt{special} option that re-computes the 1-2,1-3,1-4 topologies after bonds are deleted; see the \texttt{delete\_bonds} command for more details.

The \texttt{amber} keyword sets the 3 coefficients to 0.0, 0.0, 0.5 for LJ interactions and to 0.0, 0.0, 0.8333 for Coulombic interactions, which is the default for a commonly used version of the AMBER force field, where the last value is really 5/6. See (Cornell) for a description of the AMBER force field.

The \texttt{charmm} keyword sets the 3 coefficients to 0.0, 0.0, 0.0 for both LJ and Coulombic interactions, which is the default for a commonly used version of the CHARMM force field. Note that in pair styles \texttt{lj/charmm/coul/charmm} and \texttt{lj/charmm/coul/long} the 1-4 coefficients are defined explicitly, and these pairwise contributions are computed as part of the charmm dihedral style - see the \texttt{pair\_coeff} and \texttt{dihedral\_style} commands for more information. See (MacKerell) for a description of the CHARMM force field.

The \texttt{dreiding} keyword sets the 3 coefficients to 0.0, 0.0, 1.0 for both LJ and Coulombic interactions, which is the default for the Dreiding force field, as discussed in (Mayo).

The \texttt{fene} keyword sets the 3 coefficients to 0.0, 1.0, 1.0 for both LJ and Coulombic interactions, which is consistent with a coarse-grained polymer model with \texttt{FENE bonds}. See (Kremer) for a description of FENE bonds.

The \texttt{lj/coul}, \texttt{lj}, and \texttt{coul} keywords allow the 3 coefficients to be set explicitly. The \texttt{lj/coul} keyword sets both the LJ and Coulombic coefficients to the same 3 values. The \texttt{lj} and \texttt{coul} keywords only set either the LJ or Coulombic coefficients. Use both of them if you wish to set the LJ coefficients to different values than the Coulombic coefficients.
The *angle* keyword allows the 1-3 weighting factor to be ignored for individual atom pairs if they are not listed as the first and last atoms in any angle defined in the simulation or as 1,3 or 2,4 atoms in any dihedral defined in the simulation. For example, imagine the 1-3 weighting factor is set to 0.5 and you have a linear molecule with 4 atoms and bonds as follows: 1-2-3-4. If your data file defines 1-2-3 as an angle, but does not define 2-3-4 as an angle or 1-2-3-4 as a dihedral, then the pairwise interaction between atoms 1 and 3 will always be weighted by 0.5, but different force fields use different rules for weighting the pairwise interaction between atoms 2 and 4. If the *angle* keyword is specified as yes, then the pairwise interaction between atoms 2 and 4 will be unaffected (full weighting of 1.0). If the *angle* keyword is specified as no which is the default, then the 2,4 interaction will also be weighted by 0.5.

The *dihedral* keyword allows the 1-4 weighting factor to be ignored for individual atom pairs if they are not listed as the first and last atoms in any dihedral defined in the simulation. For example, imagine the 1-4 weighting factor is set to 0.5 and you have a linear molecule with 5 atoms and bonds as follows: 1-2-3-4-5. If your data file defines 1-2-3-4 as a dihedral, but does not define 2-3-4-5 as a dihedral, then the pairwise interaction between atoms 1 and 4 will always be weighted by 0.5, but different force fields use different rules for weighting the pairwise interaction between atoms 2 and 5. If the *dihedral* keyword is specified as yes, then the pairwise interaction between atoms 2 and 5 will be unaffected (full weighting of 1.0). If the *dihedral* keyword is specified as no which is the default, then the 2,5 interaction will also be weighted by 0.5.

**Note:** LAMMPS stores and maintains a data structure with a list of the first, second, and third neighbors of each atom (within the bond topology of the system). If new bonds are created (or molecules added containing atoms with more special neighbors), the size of this list needs to grow. Note that adding a single bond always adds a new first neighbor but may also induce *many* new second and third neighbors, depending on the molecular topology of your system. Using the *extra/special/per/atom* keyword to either read_data or create_box reserves empty space in the list for this N additional first, second, or third neighbors to be added. If you do not do this, you may get an error when bonds (or molecules) are added.

**Note:** If you reuse this command in an input script, you should set all the options you need each time. This command cannot be used a second time incrementally. E.g. these two commands:

```
sicpecial_bonds lj 0.0 1.0 1.0
special_bonds coul 0.0 0.0 1.0
```

are not the same as

```
sicpecial_bonds lj 0.0 1.0 1.0 coul 0.0 0.0 1.0
```

In the first case you end up with (after the second command):

<table>
<thead>
<tr>
<th>LJ</th>
<th>Coul</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0 0.0 0.0</td>
<td>0.0 0.0 1.0</td>
</tr>
</tbody>
</table>

while only in the second case, you get the desired settings of:

<table>
<thead>
<tr>
<th>LJ</th>
<th>Coul</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0 1.0 1.0</td>
<td>0.0 0.0 1.0</td>
</tr>
</tbody>
</table>

This happens because the LJ (and Coul) settings are reset to their default values before modifying them, each time the *special_bonds* command is issued.

17.116 suffix command

17.116.1 Syntax

suffix style args

- style = off or on or gpu or intel or kk or omp or opt or hybrid
- args = for hybrid style, default suffix to be used and alternative suffix

17.116.2 Examples

suffix off
suffix on
suffix gpu
suffix intel
suffix hybrid intel omp
suffix kk
This command allows you to use variants of various styles if they exist. In that respect it operates the same as the `-suffix command-line switch`. It also has options to turn off or back on any suffix setting made via the command line.

The specified style can be `gpu`, `intel`, `kk`, `omp`, `opt` or `hybrid`. These refer to optional packages that LAMMPS can be built with, as described on the `Build package` doc page. The “gpu” style corresponds to the GPU package, the “intel” style to the USER-INTEL package, the “kk” style to the KOKKOS package, the “omp” style to the USER-OMP package, and the “opt” style to the OPT package.

These are the variants these packages provide:

- **GPU** = a handful of pair styles and the PPPM kspace_style, optimized to run on one or more GPUs or multicore CPU/GPU nodes
- **USER-INTEL** = a collection of pair styles and neighbor routines optimized to run in single, mixed, or double precision on CPUs and Intel(R) Xeon Phi(TM) co-processors.
- **KOKKOS** = a collection of atom, pair, and fix styles optimized to run using the Kokkos library on various kinds of hardware, including GPUs via CUDA and many-core chips via OpenMP or threading.
- **USER-OMP** = a collection of pair, bond, angle, dihedral, improper, kspace, compute, and fix styles with support for OpenMP multi-threading
- **OPT** = a handful of pair styles, cache-optimized for faster CPU performance
- **HYBRID** = a combination of two packages can be specified (see below)

As an example, all of the packages provide a `pair_style lj/cut` variant, with style names `lj/cut/opt`, `lj/cut/omp`, `lj/cut/gpu`, `lj/cut/intel`, or `lj/cut/kk`. A variant styles can be specified explicitly in your input script, e.g. `pair_style lj/cut/gpu`. If the suffix command is used with the appropriate style, you do not need to modify your input script. The specified suffix (`opt,omp,gpu,intel,kk`) is automatically appended whenever your input script command creates a new `atom`, `pair`, `bond`, `angle`, `dihedral`, `improper`, `kspace`, `fix`, `compute`, or `run` style. If the variant version does not exist, the standard version is created.

For “hybrid”, two packages are specified. The first is used whenever available. If a style with the first suffix is not available, the style with the suffix for the second package will be used if available. For example, “hybrid intel omp” will use styles from the USER-INTEL package as a first choice and styles from the USER-OMP package as a second choice if no USER-INTEL variant is available.

If the specified style is `off`, then any previously specified suffix is temporarily disabled, whether it was specified by a command-line switch or a previous suffix command. If the specified style is `on`, a disabled suffix is turned back on.

The use of these 2 commands lets your input script use a standard LAMMPS style (i.e. a non-accelerated variant), which can be useful for testing or benchmarking purposes. Of course this is also possible by not using any suffix commands, and explicitly appending or not appending the suffix to the relevant commands in your input script.

**Note:** The default `run_style` verlet is invoked prior to reading the input script and is therefore not affected by a suffix command in the input script. The KOKKOS package requires “run_style verlet/kk”, so when using the KOKKOS package it is necessary to either use the command line “-sf kk” command or add an explicit “run_style verlet” command to the input script.

17.117.3 Description

Run a temperature accelerated dynamics (TAD) simulation. This method requires two or more partitions to perform NEB transition state searches.

TAD is described in this paper by Art Voter. It is a method that uses accelerated dynamics at an elevated temperature to generate results at a specified lower temperature. A good overview of accelerated dynamics methods (AMD) for such systems is given in this review paper from the same group. To quote from the review paper: “The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by \( p(t) = k \exp(-kt) \) where \( k \) is the rate constant.”

TAD is a suitable AMD method for infrequent-event systems, where in addition, the transition kinetics are well-approximated by harmonic transition state theory (hTST). In hTST, the temperature dependence of transition rates follows the Arrhenius relation. As a consequence a set of event times generated in a high-temperature simulation can be mapped to a set of much longer estimated times in the low-temperature system. However, because this mapping involves the energy barrier of the transition event, which is different for each event, the first event at the high temperature may not be the earliest event at the low temperature. TAD handles this by first generating a set of possible events from the current basin. After each event, the simulation is reflected backwards into the current basin. This is repeated until the stopping criterion is satisfied, at which point the event with the earliest low-temperature occurrence time is selected. The stopping criterion is that the confidence measure be greater than \( 1 - \delta \). The confidence measure is the probability that no earlier low-temperature event will occur at some later time in the high-temperature simulation. hTST provides an lower bound for this probability, based on the user-specified minimum pre-exponential factor (reciprocal of \( t_{max} \)).

In order to estimate the energy barrier for each event, the TAD method invokes the NEB method. Each NEB replica runs on a partition of processors. The current NEB implementation in LAMMPS restricts you to having exactly one processor per replica. For more information, see the documentation for the neb command. In the current LAMMPS implementation of TAD, all the non-NEB TAD operations are performed on the first partition, while the other partitions remain idle. See the Howto replica doc page for further discussion of multi-replica simulations.

A TAD run has several stages, which are repeated each time an event is performed. The logic for a TAD run is as follows:

```
while (time remains):
    while (time < tstop):
        until (event occurs):
            run dynamics for t_event steps
            quench
            run neb calculation using all replicas
            compute tlo from energy barrier
            update earliest event
            update tstop
            reflect back into current basin
            execute earliest event
```
Before this outer loop begins, the initial potential energy basin is identified by quenching (an energy minimization, see below) the initial state and storing the resulting coordinates for reference.

Inside the inner loop, dynamics is run continuously according to whatever integrator has been specified by the user, stopping every \( t_{\text{event}} \) steps to check if a transition event has occurred. This check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the \texttt{min_style} command; its default is the CG minimizer. The tolerances and limits for each quench can be set by the \texttt{min} keyword. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event.

The event check is performed by a compute with the specified \texttt{compute-ID}. Currently there is only one compute that works with the TAD command, which is the \texttt{compute event/displace} command. Other event-checking computes may be added. \texttt{Compute event/displace} checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an “event” has occurred.

The NEB calculation is similar to that invoked by the \texttt{neb} command, except that the final state is generated internally, instead of being read in from a file. The style of minimization performed by NEB is determined by the \texttt{neb_style} keyword and must be a damped dynamics minimizer. The tolerances and limits for each NEB calculation can be set by the \texttt{neb} keyword. As discussed on the \texttt{neb}, it is often advantageous to use a larger timestep for NEB than for normal dynamics. Since the size of the timestep set by the \texttt{timestep} command is used by TAD for performing dynamics, there is a \texttt{neb_step} keyword which can be used to set a larger timestep for each NEB calculation if desired.

A key aspect of the TAD method is setting the stopping criterion appropriately. If this criterion is too conservative, then many events must be generated before one is finally executed. Conversely, if this criterion is too aggressive, high-entropy high-barrier events will be over-sampled, while low-entropy low-barrier events will be under-sampled. If the lowest pre-exponential factor is known fairly accurately, then it can be used to estimate \( t_{\text{max}} \), and the value of \texttt{delta} can be set to the desired confidence level e.g. \( \delta = 0.05 \) corresponds to 95% confidence. However, for systems where the dynamics are not well characterized (the most common case), it will be necessary to experiment with the values of \texttt{delta} and \texttt{tmax} to get a good trade-off between accuracy and performance.

A second key aspect is the choice of \( t_{\text{hi}} \). A larger value greatly increases the rate at which new events are generated. However, too large a value introduces errors due to anharmonicity (not accounted for within hTST). Once again, for any given system, experimentation is necessary to determine the best value of \( t_{\text{hi}} \).

Five kinds of output can be generated during a TAD run: event statistics, NEB statistics, thermodynamic output by each replica, dump files, and restart files.

Event statistics are printed to the screen and master \texttt{log.lammps} file each time an event is executed. The quantities are the timestep, CPU time, global event number \( N \), local event number \( M \), event status, energy barrier, time margin, \( t_{\text{lo}} \) and \( \text{delt}_{\text{lo}} \). The timestep is the usual LAMMPS timestep, which corresponds to the high-temperature time at which the event was detected, in units of timestep. The CPU time is the total processor time since the start of the TAD run. The global event number \( N \) is a counter that increments with each executed event. The local event number \( M \) is a counter that resets to zero upon entering each new basin. The event status is \( E \) when an event is executed, and is \( D \) for an event that is detected, while \( DF \) is for a detected event that is also the earliest (first) event at the low temperature.

The time margin is the ratio of the high temperature time in the current basin to the stopping time. This last number can be used to judge whether the stopping time is too short or too long (see above).

\( t_{\text{lo}} \) is the low-temperature event time when the current basin was entered, in units of timestep. \( \text{delt}_{\text{lo}} \) is equal to the high-temperature time since entering the current basin, scaled by an exponential factor that depends on the hi/lo temperature ratio and the energy barrier for that event.

On lines for executed events, with status \( E \), the global event number is incremented by one, the local event number and time margin are reset to zero, while the global event number, energy barrier, and \( \text{delt}_{\text{lo}} \) match the last event with
status $DF$ in the immediately preceding block of detected events. The low-temperature event time $t_{lo}$ is incremented by $\Delta t_{lo}$.

NEB statistics are written to the file specified by the $neb\_log$ keyword. If the keyword value is “none”, then no NEB statistics are printed out. The statistics are written every $N_{every}$ timesteps. See the $neb$ command for a full description of the NEB statistics. When invoked from TAD, NEB statistics are never printed to the screen.

Because the NEB calculation must run on multiple partitions, LAMMPS produces additional screen and log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For the TAD command, these contain the thermodynamic output of each NEB replica. In addition, the log file for the first partition, log.lammps.0, will contain thermodynamic output from short runs and minimizations corresponding to the dynamics and quench operations, as well as a line for each new detected event, as described above.

After the TAD command completes, timing statistics for the TAD run are printed in each replica’s log file, giving a breakdown of how much CPU time was spent in each stage (NEB, dynamics, quenching, etc).

Any $dump$ files defined in the input script will be written to during a TAD run at timesteps when an event is executed. This means the requested dump frequency in the $dump$ command is ignored. There will be one dump file (per dump command) created for all partitions. The atom coordinates of the dump snapshot are those of the minimum energy configuration resulting from quenching following the executed event. The timesteps written into the dump files correspond to the timestep at which the event occurred and NOT the clock. A dump snapshot corresponding to the initial minimum state used for event detection is written to the dump file at the beginning of each TAD run.

If the $restart$ command is used, a single restart file for all the partitions is generated, which allows a TAD run to be continued by a new input script in the usual manner. The restart file is generated after an event is executed. The restart file contains a snapshot of the system in the new quenched state, including the event number and the low-temperature time. The restart frequency specified in the $restart$ command is interpreted differently when performing a TAD run. It does not mean the timestep interval between restart files. Instead it means an event interval for executed events. Thus a frequency of 1 means write a restart file every time an event is executed. A frequency of 10 means write a restart file every 10th executed event. When an input script reads a restart file from a previous TAD run, the new script can be run on a different number of replicas or processors.

Note that within a single state, the dynamics will typically temporarily continue beyond the event that is ultimately chosen, until the stopping criterion is satisfied. When the event is eventually executed, the timestep counter is reset to the value when the event was detected. Similarly, after each quench and NEB minimization, the timestep counter is reset to the value at the start of the minimization. This means that the timesteps listed in the replica log files do not always increase monotonically. However, the timestep values printed to the master log file, dump files, and restart files are always monotonically increasing.

### 17.117.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the $Build\ package$ doc page for more info.

$N$ setting must be integer multiple of $t_{event}$.

Runs restarted from restart files written during a TAD run will only produce identical results if the user-specified integrator supports exact restarts. So $fix\ nvt$ will produce an exact restart, but $fix\ langevin$ will not.

This command cannot be used when any fixes are defined that keep track of elapsed time to perform time-dependent operations. Examples include the “ave” fixes such as $fix\ ave/chunk$. Also $fix\ dt/reset$ and $fix\ deposit$.

17.117.5 Related commands

*compute event/displace, min_modify, min_style, run_style, minimize, temper, neb, prd*

17.117.6 Default

The option defaults are \texttt{min} = 0.1 0.1 40 50, \texttt{neb} = 0.01 100 100 10, \texttt{neb\_style} = \texttt{quickmin}, \texttt{neb\_step} = the same timestep set by the \texttt{timestep} command, and \texttt{neb\_log} = “none”.

17.118 temper command

17.118.1 Syntax

\begin{verbatim}
  temper N M temp fix-ID seed1 seed2 index
\end{verbatim}

- \texttt{N} = total \# of timesteps to run
- \texttt{M} = attempt a tempering swap every this many steps
- \texttt{temp} = initial temperature for this ensemble
- \texttt{fix-ID} = ID of the fix that will control temperature during the run
- \texttt{seed1} = random \# seed used to decide on adjacent temperature to partner with
- \texttt{seed2} = random \# seed for Boltzmann factor in Metropolis swap
- \texttt{index} = which temperature (0 to \texttt{N}-1) I am simulating (optional)

17.118.2 Examples

\begin{verbatim}
  temper 100000 100 $t\ tempfix 0 58728
  temper 40000 100 $t\ tempfix 0 32285 $w
\end{verbatim}

17.118.3 Description

Run a parallel tempering or replica exchange simulation using multiple replicas (ensembles) of a system. Two or more replicas must be used.

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the \texttt{-partition} command-line switch. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g. you can run a 10-replica simulation on one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See the \textit{Howto replica} doc page for further discussion.

Each replica’s temperature is controlled at a different value by a fix with \texttt{fix-ID} that controls temperature. Most thermostat fix styles (with and without included time integration) are supported. The command will print an error message and abort, if the chosen fix is unsupported. The desired temperature is specified by \texttt{temp}, which is typically
a variable previously set in the input script, so that each partition is assigned a different temperature. See the `variable` command for more details. For example:

```plaintext
variable t world 300.0 310.0 320.0 330.0
fix myfix all nvt temp $t $t 100.0
temper 100000 100 $t myfix 3847 58382
```

would define 4 temperatures, and assign one of them to the thermostat used by each replica, and to the temper command.

As the tempering simulation runs for \(N\) timesteps, a temperature swap between adjacent ensembles will be attempted every \(M\) timesteps. If `seed1` is 0, then the swap attempts will alternate between odd and even pairings. If `seed1` is non-zero then it is used as a seed in a random number generator to randomly choose an odd or even pairing each time. Each attempted swap of temperatures is either accepted or rejected based on a Boltzmann-weighted Metropolis criterion which uses `seed2` in the random number generator.

As a tempering run proceeds, multiple log files and screen output files are created, one per replica. By default these files are named log.lammps.M and screen.M where \(M\) is the replica number from 0 to \(N-1\), with \(N = \#\) of replicas. See the `-log and -screen command-line switches` for info on how to change these names.

The main screen and log file (log.lammps) will list information about which temperature is assigned to each replica at each thermodynamic output timestep. E.g. for a simulation with 16 replicas:

```
Running on 16 partitions of processors
Step T0 T1 T2 T3 T4 T5 T6 T7 T8 T9 T10 T11 T12 T13 T14 T15
 0  0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
500 1 0 3 2 5 4 6 7 8 9 10 11 12 13 14 15
1000 2 0 4 1 5 3 6 7 8 9 10 11 12 14 13 15
1500 2 1 4 0 5 3 6 7 9 8 10 11 12 14 13 15
2000 2 1 3 0 6 4 5 7 10 8 9 11 12 14 13 15
2500 2 1 3 0 6 4 5 7 11 8 9 10 12 14 13 15
...
```

The column headings T0 to TN-1 mean which temperature is currently assigned to the replica 0 to N-1. Thus the columns represent replicas and the value in each column is its temperature (also numbered 0 to N-1). For example, a 0 in the fourth column (column T3, step 2500) means that the fourth replica is assigned temperature 0, i.e. the lowest temperature. You can verify this time sequence of temperature assignments for the Nth replica by comparing the Nth column of screen output to the thermodynamic data in the corresponding log.lammps.N or screen.N files as time proceeds.

You can have each replica create its own dump file in the following manner:

```plaintext
variable rep world 0 1 2 3 4 5 6 7
dump 1 all atom 1000 dump.temper.${rep}
```

**Note:** Each replica’s dump file will contain a continuous trajectory for its atoms where the temperature varies over time as swaps take place involving that replica. If you want a series of dump files, each with snapshots (from all replicas) that are all at a single temperature, then you will need to post-process the dump files using the information from the log.lammps file. E.g. you could produce one dump file with snapshots at 300K (from all replicas), another with snapshots at 310K, etc. Note that these new dump files will not contain “continuous trajectories” for individual atoms, because two successive snapshots (in time) may be from different replicas. The reorder_remd_traj python script can do the reordering for you (and additionally also calculated configurational log-weights of trajectory snapshots in the canonical ensemble). The script can be found in the tools/replica directory while instructions on how to use it is available in doc/Tools (in brief) and as a README file in tools/replica (in detail).

The last argument `index` in the temper command is optional and is used when restarting a tempering run from a set of
restart files (one for each replica) which had previously swapped to new temperatures. The index value (from 0 to N-1, where N is the # of replicas) identifies which temperature the replica was simulating on the timestep the restart files were written. Obviously, this argument must be a variable so that each partition has the correct value. Set the variable to the N values listed in the log file for the previous run for the replica temperatures at that timestep. For example if the log file listed the following for a simulation with 5 replicas:

```
500000 2 4 0 1 3
```

then a setting of

```
variable w world 2 4 0 1 3
```

would be used to restart the run with a tempering command like the example above with $w$ as the last argument.

### 17.118.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

### 17.118.5 Related commands

`variable, prd, neb`

### 17.118.6 Default

none

### 17.119 temper/grem command

#### 17.119.1 Syntax

```
temper/grem N M lambda fix-ID thermostat-ID seed1 seed2 index
```

- N = total # of timesteps to run
- M = attempt a tempering swap every this many steps
- lambda = initial lambda for this ensemble
- fix-ID = ID of `fix grem`
- thermostat-ID = ID of the thermostat that controls kinetic temperature
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- index = which temperature (0 to N-1) I am simulating (optional)
17.119.2 Examples

```
temper/grem 100000 1000 $\{\text{lambda}\}$ fxgREM fxnvt 0 58728
temper/grem 40000 100 $\{\text{lambda}\}$ fxgREM fxnpt 0 32285 $\{\text{walkers}\}$
```

17.119.3 Description

Run a parallel tempering or replica exchange simulation in LAMMPS partition mode using multiple generalized replicas (ensembles) of a system defined by `fix grem`, which stands for the generalized replica exchange method (gREM) originally developed by (Kim). It uses non-Boltzmann ensembles to sample over first order phase transitions. The is done by defining replicas with an enthalpy dependent effective temperature.

Two or more replicas must be used. See the `temper` command for an explanation of how to run replicas on multiple partitions of one or more processors.

This command is a modification of the `temper` command and has the same dependencies, restraints, and input variables which are discussed there in greater detail.

Instead of temperature, this command performs replica exchanges in lambda as per the generalized ensemble enforced by `fix grem`. The desired lambda is specified by `lambda`, which is typically a variable previously set in the input script, so that each partition is assigned a different temperature. See the `variable` command for more details. For example:

```
variable lambda world 400 420 440 460
fix fxnvt all nvt temp 300.0 300.0 100.0
fix fxgREM all grem $\{\text{lambda}\}$ -0.05 -50000 fxnvt
temper/grem 100000 100 $\{\text{lambda}\}$ fxgREM fxnvt 3847 58382
```

would define 4 lambdas with constant kinetic temperature but unique generalized temperature, and assign one of them to `fix grem` used by each replica, and to the grem command.

As the gREM simulation runs for $N$ timesteps, a swap between adjacent ensembles will be attempted every $M$ timesteps. If `seed1` is 0, then the swap attempts will alternate between odd and even pairings. If `seed1` is non-zero then it is used as a seed in a random number generator to randomly choose an odd or even pairing each time. Each attempted swap of temperatures is either accepted or rejected based on a Metropolis criterion, derived for gREM by (Kim), which uses `seed2` in the random number generator.

File management works identical to the `temper` command. Dump files created by this fix contain continuous trajectories and require post-processing to obtain per-replica information.

The last argument `index` in the grem command is optional and is used when restarting a run from a set of restart files (one for each replica) which had previously swapped to new lambda. This is done using a variable. For example if the log file listed the following for a simulation with 5 replicas:

```
500000 2 4 0 1 3
```

then a setting of

```
variable walkers world 2 4 0 1 3
```

would be used to restart the run with a grem command like the example above with `$\{\text{walkers}\}$` as the last argument. This functionality is identical to `temper`.

17.119. `temper/grem command`
17.119.4 Restrictions

This command can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

This command must be used with fix grem.

17.119.5 Related commands

fix grem, temper, variable

17.119.6 Default

temper/npt 2500000 1000 300 nptfix 0 32285 $p
temper/npt 5000000 2000 $t nptfix 0 12523 1 $w
```
17.120.3 Description

Run a parallel tempering or replica exchange simulation using multiple replicas (ensembles) of a system in the isothermal-isobaric (NPT) ensemble. The command temper/npt works like `temper` but requires running replicas in the NPT ensemble instead of the canonical (NVT) ensemble and allows for pressure to be set in the ensembles. These multiple ensembles can run in parallel at different temperatures or different pressures. The acceptance criteria for temper/npt is specific to the NPT ensemble and can be found in references (Okabe) and (Mori).

Apart from the difference in acceptance criteria and the specification of pressure, this command works much like the `temper` command. See the documentation on `temper` for information on how the parallel tempering is handled in general.

17.120.4 Restrictions

This command can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

This command should be used with a fix that maintains the isothermal-isobaric (NPT) ensemble.

17.121 thermo command

17.121.1 Syntax

```
thermo N
```

- N = output thermodynamics every N timesteps
- N can be a variable (see below)
17.121.2 Examples

```plaintext
thermo 100
```

17.121.3 Description

Compute and print thermodynamic info (e.g. temperature, energy, pressure) on timesteps that are a multiple of \( N \) and at the beginning and end of a simulation. A value of 0 will only print thermodynamics at the beginning and end.

The content and format of what is printed is controlled by the `thermo_style` and `thermo_modify` commands.

Instead of a numeric value, \( N \) can be specified as an `equal-style variable`, which should be specified as `v_name`, where `name` is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which thermodynamic info will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the `stagger()` and `logfreq()` and `stride()` math functions for `equal-style variables`, as examples of useful functions to use in this context. Other similar math functions could easily be added as options for `equal-style variables`.

For example, the following commands will output thermodynamic info at timesteps 0,10,20,30,100,200,300,1000,2000,etc:

```plaintext
variable s equal logfreq(10,3,10)
thermo v_s
```

```

17.122 thermo_modify command

17.122.1 Syntax

```plaintext
thermo_modify keyword value ...
```

- one or more keyword/value pairs may be listed
  - keyword = `lost` or `lost/bond` or `norm` or `flush` or `line` or `format` or `temp` or `press`
  - `lost` value = `error` or `warn` or `ignore`
  - `lost/bond` value = `error` or `warn` or `ignore`
  - `norm` value = `yes` or `no`
flush value = yes or no
line value = one or multi
format values = line string, int string, float string, M string, or none
    string = C-style format string
    M = integer from 1 to N, where N = # of quantities being output
temp value = compute ID that calculates a temperature
press value = compute ID that calculates a pressure

17.122.2 Examples

thermo_modify lost ignore flush yes
thermo_modify temp myTemp format 3 %15.8g
thermo_modify temp myTemp format line "%ld %g %g %15.8g"
thermo_modify line multi format float %g

17.122.3 Description

Set options for how thermodynamic information is computed and printed by LAMMPS.

Note: These options apply to the currently defined thermo style. When you specify a thermo_style command, all thermodynamic settings are restored to their default values, including those previously reset by a thermo_modify command. Thus if your input script specifies a thermo_style command, you should use the thermo_modify command after it.

The lost keyword determines whether LAMMPS checks for lost atoms each time it computes thermodynamics and what it does if atoms are lost. An atom can be “lost” if it moves across a non-periodic simulation box boundary or if it moves more than a box length outside the simulation domain (or more than a processor sub-domain length) before reneighboring occurs. The latter case is typically due to bad dynamics, e.g. too large a timestep or huge forces and velocities. If the value is ignore, LAMMPS does not check for lost atoms. If the value is error or warn, LAMMPS checks and either issues an error or warning. The code will exit with an error and continue with a warning. A warning will only be issued once, the first time an atom is lost. This can be a useful debugging option.

The lost/bond keyword determines whether LAMMPS throws an error or not if an atom in a bonded interaction (bond, angle, etc) cannot be found when it creates bonded neighbor lists. By default this is a fatal error. However in some scenarios it may be desirable to only issue a warning or ignore it and skip the computation of the missing bond, angle, etc. An example would be when gas molecules in a vapor are drifting out of the box through a fixed boundary condition (see the boundary command). In this case one atom may be deleted before the rest of the molecule is, on a later timestep.

The norm keyword determines whether various thermodynamic output values are normalized by the number of atoms or not, depending on whether it is set to yes or no. Different unit styles have different defaults for this setting (see below). Even if norm is set to yes, a value is only normalized if it is an “extensive” quantity, meaning that it scales with the number of atoms in the system. For the thermo keywords described by the doc page for the thermo_style command, all energy-related keywords are extensive, such as pe or ebond or enthalpy. Other keywords such as temp or press are “intensive” meaning their value is independent (in a statistical sense) of the number of atoms in the system and thus are never normalized. For thermodynamic output values extracted from fixes and computes in a thermo_style custom command, the doc page for the individual fix or compute lists whether the value is “extensive” or “intensive” and thus whether it is normalized. Thermodynamic output values calculated by a variable formula are assumed to be “intensive” and thus are never normalized. You can always include a divide by the number of atoms in the variable formula if this is not the case.

17.122. thermo_modify command
The **flush** keyword invokes a flush operation after thermodynamic info is written to the log file. This insures the output in that file is current (no buffering by the OS), even if LAMMPS halts before the simulation completes.

The **line** keyword determines whether thermodynamics will be output as a series of numeric values on one line or in a multi-line format with 3 quantities with text strings per line and a dashed-line header containing the timestep and CPU time. This modify option overrides the one and multi thermo_style settings.

The **format** keyword can be used to change the default numeric format of any of quantities the thermo_style command outputs. All the specified format strings are C-style formats, e.g. as used by the C/C++ printf() command. The **line** keyword takes a single argument which is the format string for the entire line of thermo output, with N fields, which you must enclose in quotes if it is more than one field. The **int** and **float** keywords take a single format argument and are applied to all integer or floating-point quantities output. The setting for **M string** also takes a single format argument which is used for the Mth value output in each line, e.g. the fifth column is output in high precision for “format 5 %20.15g”.

The **format** keyword can be used multiple times. The precedence is that for each value in a line of output, the **M** format (if specified) is used, else the **int** or **float** setting (if specified) is used, else the **line** setting (if specified) for that value is used, else the default setting is used. A setting of none clears all previous settings, reverting all values to their default format.

**Note:** The thermo output values **step** and **atoms** are stored internally as 8-byte signed integers, rather than the usual 4-byte signed integers. When specifying the **format int** option you can use a “%d”-style format identifier in the format string and LAMMPS will convert this to the corresponding 8-byte form when it is applied to those keywords. However, when specifying the **line** option or **format M string** option for **step** and **natoms**, you should specify a format string appropriate for an 8-byte signed integer, e.g. one with “%ld”.

The **temp** keyword is used to determine how thermodynamic temperature is calculated, which is used by all thermo quantities that require a temperature (“temp”, “press”, “ke”, “etotal”, “enthalpy”, “pxx”, etc). The specified compute ID must have been previously defined by the user via the compute command and it must be a style of compute that calculates a temperature. As described in the thermo_style command, thermo output uses a default compute for temperature with ID = thermo_temp. This option allows the user to override the default.

The **press** keyword is used to determine how thermodynamic pressure is calculated, which is used by all thermo quantities that require a pressure (“press”, “enthalpy”, “pxx”, etc). The specified compute ID must have been previously defined by the user via the compute command and it must be a style of compute that calculates a pressure. As described in the thermo_style command, thermo output uses a default compute for pressure with ID = thermo_press. This option allows the user to override the default.

**Note:** If both the **temp** and **press** keywords are used in a single thermo_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a pressure compute defines its own temperature compute as an argument when it is specified. The **temp** keyword will override this (for the pressure compute being used by thermodynamics), but only if the **temp** keyword comes after the **press** keyword. If the **temp** keyword comes before the **press** keyword, then the new pressure compute specified by the **press** keyword will be unaffected by the **temp** setting.
17.122.4 Restrictions
none

17.122.5 Related commands
thermo, thermo_style

17.122.6 Default
The option defaults are lost = error, norm = yes for unit style of lj, norm = no for unit style of real and metal, flush = no, and temp/press = compute IDs defined by thermo_style.
The defaults for the line and format options depend on the thermo style. For styles “one” and “custom”, the line and format defaults are “one”, “%8d”, and “%12.8g”. For style “multi”, the line and format defaults are “multi”, “%8d”, and “%14.4f”.

17.123 thermo_style command

17.123.1 Syntax
thermo_style style args

- style = one or multi or custom
- args = list of arguments for a particular style
  - one args = none
  - multi args = none
  - custom args = list of keywords

possible keywords = step, elapsed, elaplong, dt, time,

17.123. thermo_style command
tpcpu = time per CPU second
spcpu = timesteps per CPU second
cpuremain = estimated CPU time remaining in run
part = which partition (0 to Npartition-1) this is
timeremain = remaining time in seconds on timer timeout.
atoms = # of atoms
temp = temperature
press = pressure
pe = total potential energy
ke = kinetic energy
etotal = total energy (pe + ke)
enthalpy = enthalpy (etotal + press*vol)
evdl = van der Waals pairwise energy (includes etail)
ecoul = Coulombic pairwise energy
epair = pairwise energy (evdl + ecoul + elong)
ebond = bond energy
eangle = angle energy
edihed = dihedral energy
eimp = improper energy
emol = molecular energy (ebond + eangle + edihed + eimp)
elong = long-range kspace energy
etal = van der Waals energy long-range tail correction
vol = volume
density = mass density of system
lx,ly,lz = box lengths in x,y,z
xlo,xhi,ylo,yhi,zlo,zhi = box boundaries
xy,xz,yz = box tilt for triclinic (non-orthogonal) simulation boxes
xlat,ylat,zlat = lattice spacings as calculated by lattice command
bonds,angles,dihedrals,impropers = # of these interactions defined
pxx,pyy,pzz,pxy,pxz,pyz = 6 components of pressure tensor
fmax = max component of force on any atom in any dimension
fnorm = length of force vector for all atoms
nbuild = # of neighbor list builds
ndanger = # of dangerous neighbor list builds
cella,cellb,cellc = periodic cell lattice constants a,b,c
cellalpha, cellbeta, cellgamma = periodic cell angles alpha,beta,gamma
c_ID = global scalar value calculated by a compute with ID
c_ID[I] = Ith component of global vector calculated by a compute with
- ID, I can include wildcard (see below)
c_ID[I][J] = I,J component of global array calculated by a compute
- with ID
  f_ID = global scalar value calculated by a fix with ID
  f_ID[I] = Ith component of global vector calculated by a fix with ID,
- I can include wildcard (see below)
  f_ID[I][J] = I,J component of global array calculated by a fix with ID
v_name = value calculated by an equal-style variable with name
v_name[I] = value calculated by a vector-style variable with name
17.123.2 Examples

```
thermo_style multi
thermo_style custom step temp etotal press vol
thermo_style custom step temp etotal c_myTemp v_abc
thermo_style custom step temp etotal c_myTemp[*] v_abc
```

17.123.3 Description

Set the style and content for printing thermodynamic data to the screen and log file.

Style `one` prints a one-line summary of thermodynamic info that is the equivalent of “thermo_style custom step temp epair emol etotal press”. The line contains only numeric values.

Style `multi` prints a multiple-line listing of thermodynamic info that is the equivalent of “thermo_style custom etotal ke temp pe bond eangle edihed eimp evdwl ecoul elong press”. The listing contains numeric values and a string ID for each quantity.

Style `custom` is the most general setting and allows you to specify which of the keywords listed above you want printed on each thermodynamic timestep. Note that the keywords c_ID, f_ID, v_name are references to computes, fixes, and equal-style variables that have been defined elsewhere in the input script or can even be new styles which users have added to LAMMPS. See the Modify doc page for details on the latter. Thus the custom style provides a flexible means of outputting essentially any desired quantity as a simulation proceeds.

All styles except custom have vol appended to their list of outputs if the simulation box volume changes during the simulation.

The values printed by the various keywords are instantaneous values, calculated on the current timestep. Time-averaged quantities, which include values from previous timesteps, can be output by using the f_ID keyword and accessing a fix that does time-averaging such as the fix ave/time command.

Options invoked by the thermo_modify command can be used to set the one- or multi-line format of the print-out, the normalization of thermodynamic output (total values versus per-atom values for extensive quantities (ones which scale with the number of atoms in the system), and the numeric precision of each printed value.

**Note:** When you use a “thermo_style” command, all thermodynamic settings are restored to their default values, including those previously set by a thermo_modify command. Thus if your input script specifies a thermo_style command, you should use the thermo_modify command after it.

Several of the thermodynamic quantities require a temperature to be computed: “temp”, “press”, “ke”, “etotal”, “enthalpy”, “pxx”, etc. By default this is done by using a temperature compute which is created when LAMMPS starts up, as if this command had been issued:

```
compute thermo_temp all temp
```

See the compute temp command for details. Note that the ID of this compute is thermo_temp and the group is all. You can change the attributes of this temperature (e.g. its degrees-of-freedom) via the compute_modify command. Alternatively, you can directly assign a new compute (that calculates temperature) which you have defined, to be used for calculating any thermodynamic quantity that requires a temperature. This is done via the thermo_modify command.

Several of the thermodynamic quantities require a pressure to be computed: “press”, “enthalpy”, “pxx”, etc. By default this is done by using a pressure compute which is created when LAMMPS starts up, as if this command had been issued:
**compute thermo_press all pressure thermo_temp**

See the `compute pressure` command for details. Note that the ID of this compute is `thermo_press` and the group is `all`. You can change the attributes of this pressure via the `compute_modify` command. Alternatively, you can directly assign a new compute (that calculates pressure) which you have defined, to be used for calculating any thermodynamic quantity that requires a pressure. This is done via the `thermo_modify` command.

Several of the thermodynamic quantities require a potential energy to be computed: “pe”, “etotal”, “ebond”, etc. This is done by using a `pe` compute which is created when LAMMPS starts up, as if this command had been issued:

**compute thermo_pe all pe**

See the `compute pe` command for details. Note that the ID of this compute is `thermo_pe` and the group is `all`. You can change the attributes of this potential energy via the `compute_modify` command.

The kinetic energy of the system $ke$ is inferred from the temperature of the system with $\frac{1}{2} k_B T$ of energy for each degree of freedom. Thus, using different `compute commands` for calculating temperature, via the `thermo_modify temp` command, may yield different kinetic energies, since different computes that calculate temperature can subtract out different non-thermal components of velocity and/or include different degrees of freedom (translational, rotational, etc).

The potential energy of the system $pe$ will include contributions from fixes if the `fix_modify thermo` option is set for a fix that calculates such a contribution. For example, the `fix wall/lj93` fix calculates the energy of atoms interacting with the wall. See the doc pages for “individual fixes” to see which ones contribute.

A long-range tail correction $etail$ for the van der Waals pairwise energy will be non-zero only if the `pair_modify tail` option is turned on. The $etail$ contribution is included in $evdwl$, $epair$, $pe$, and $etotal$, and the corresponding tail correction to the pressure is included in $press$ and $pxx$, $pyy$, etc.

The `step`, `elapsed`, and `elaplong` keywords refer to timestep count. `Step` is the current timestep, or iteration count when a `minimization` is being performed. `Elapsed` is the number of timesteps elapsed since the beginning of this run. `Elaplong` is the number of timesteps elapsed since the beginning of an initial run in a series of runs. See the `start` and `stop` keywords for the `run` for info on how to invoke a series of runs that keep track of an initial starting time. If these keywords are not used, then `elapsed` and `elaplong` are the same value.

The `dt` keyword is the current timestep size in time `units`. The `time` keyword is the current elapsed simulation time, also in time `units`, which is simply (`step`*`dt`) if the timestep size has not changed and the timestep has not been reset. If the timestep has changed (e.g. via `fix dt/reset`) or the timestep has been reset (e.g. via the “reset_timestep” command), then the simulation time is effectively a cumulative value up to the current point.

The `cpu` keyword is elapsed CPU seconds since the beginning of this run. The `tpcpu` and `spcpu` keywords are measures of how fast your simulation is currently running. The `tpcpu` keyword is simulation time per CPU second, where simulation time is in `time units`. E.g. for metal units, the `tpcpu` value would be picoseconds per CPU second. The `spcpu` keyword is the number of timesteps per CPU second. Both quantities are on-the-fly metrics, measured relative to the last time they were invoked. Thus if you are printing out thermodynamic output every 100 timesteps, the two keywords will continually output the time and timestep rate for the last 100 steps. The `tpcpu` keyword does not attempt to track any changes in timestep size, e.g. due to using the `fix dt/reset` command.

The `cpuremain` keyword estimates the CPU time remaining in the current run, based on the time elapsed thus far. It will only be a good estimate if the CPU time/timestep for the rest of the run is similar to the preceding timesteps. On the initial timestep the value will be 0.0 since there is no history to estimate from. For a minimization run performed by the “minimize” command, the estimate is based on the `maxiter` parameter, assuming the minimization will proceed for the maximum number of allowed iterations.
The `part` keyword is useful for multi-replica or multi-partition simulations to indicate which partition this output and this file corresponds to, or for use in a variable to append to a filename for output specific to this partition. See discussion of the `-partition command-line switch` for details on running in multi-partition mode.

The `timeremain` keyword returns the remaining seconds when a timeout has been configured via the `timer timeout` command. If the timeout timer is inactive, the value of this keyword is 0.0 and if the timer is expired, it is negative. This allows for example to exit loops cleanly, if the timeout is expired with:

```bash
if "$\{timeremain\} < 0.0" then "quit 0"
```

The `fmax` and `fnorm` keywords are useful for monitoring the progress of an energy minimization. The `fmax` keyword calculates the maximum force in any dimension on any atom in the system, or the infinity-norm of the force vector for the system. The `fnorm` keyword calculates the 2-norm or length of the force vector.

The `nbuild` and `ndanger` keywords are useful for monitoring neighbor list builds during a run. Note that both these values are also printed with the end-of-run statistics. The `nbuild` keyword is the number of re-builds during the current run. The `ndanger` keyword is the number of re-builds that LAMMPS considered potentially “dangerous”. If atom movement triggered neighbor list rebuilding (see the `neigh_modify` command), then dangerous reneighborings are those that were triggered on the first timestep atom movement was checked for. If this count is non-zero you may wish to reduce the delay factor to insure no force interactions are missed by atoms moving beyond the neighbor skin distance before a rebuild takes place.

The keywords `cella`, `cellb`, `cellc`, `cellalpha`, `cellbeta`, `cellgamma`, correspond to the usual crystallographic quantities that define the periodic unit cell of a crystal. See the `Howto triclinic` doc page for a geometric description of triclinic periodic cells, including a precise definition of these quantities in terms of the internal LAMMPS cell dimensions `lx`, `ly`, `lz`, `yz`, `xz`, `xy`.

For output values from a compute or fix, the bracketed index I used to index a vector, as in `c_ID[I]` or `f_ID[I]`, can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “n*” or “*n” or “m*n”. If N = the size of the vector (for `mode = scalar`) or the number of columns in the array (for `mode = vector`), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual elements of the vector had been listed one by one. E.g. these 2 thermo_style commands are equivalent, since the compute temp command creates a global vector with 6 values.

```bash
compute myTemp all temp
thermo_style custom step temp etotal c_myTemp[*]
thermo_style custom step temp etotal &
```

The `c_ID` and `c_ID[I]` and `c_ID[I][J]` keywords allow global values calculated by a compute to be output. As discussed on the `compute` doc page, computes can calculate global, per-atom, or local values. Only global values can be referenced by this command. However, per-atom compute values for an individual atom can be referenced in a variable and the variable referenced by thermo_style custom, as discussed below. See the discussion above for how the I in `c_ID[I]` can be specified with a wildcard asterisk to effectively specify multiple values from a global compute vector.

The ID in the keyword should be replaced by the actual ID of a compute that has been defined elsewhere in the input script. See the `compute` command for details. If the compute calculates a global scalar, vector, or array, then the keyword formats with 0, 1, or 2 brackets will reference a scalar value from the compute.

Note that some computes calculate “intensive” global quantities like temperature; others calculate “extensive” global quantities like kinetic energy that are summed over all atoms in the compute group. Intensive quantities are printed
directly without normalization by thermo_style custom. Extensive quantities may be normalized by the total number of atoms in the simulation (NOT the number of atoms in the compute group) when output, depending on the thermo_modify norm option being used.

The \texttt{f\_ID} and \texttt{f\_ID[I]} and \texttt{f\_ID[I][J]} keywords allow global values calculated by a fix to be output. As discussed on the \texttt{fix} doc page, fixes can calculate global, per-atom, or local values. Only global values can be referenced by this command. However, per-atom fix values can be referenced for an individual atom in a \texttt{variable} and the variable referenced by thermo_style custom, as discussed below. See the discussion above for how the \texttt{I} in \texttt{f\_ID[I]} can be specified with a wildcard asterisk to effectively specify multiple values from a global fix vector.

The \texttt{ID} in the keyword should be replaced by the actual ID of a fix that has been defined elsewhere in the input script. See the \texttt{fix} command for details. If the fix calculates a global scalar, vector, or array, then the keyword formats with 0, 1, or 2 brackets will reference a scalar value from the fix.

Note that some fixes calculate “intensive” global quantities like timestep size; others calculate “extensive” global quantities like energy that are summed over all atoms in the fix group. Intensive quantities are printed directly without normalization by thermo_style custom. Extensive quantities may be normalized by the total number of atoms in the simulation (NOT the number of atoms in the fix group) when output, depending on the thermo_modify norm option being used.

The \texttt{v\_name} keyword allow the current value of a variable to be output. The name in the keyword should be replaced by the variable name that has been defined elsewhere in the input script. Only equal-style and vector-style variables can be referenced; the latter requires a bracketed term to specify the Ith element of the vector calculated by the variable. However, an atom-style variable can be referenced for an individual atom by an equal-style variable and that variable referenced. See the \texttt{variable} command for details. Variables of style \texttt{equal} and \texttt{vector} and \texttt{atom} define a formula which can reference per-atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when evaluated, so this is a very general means of creating thermodynamic output.

Note that equal-style and vector-style variables are assumed to produce “intensive” global quantities, which are thus printed as-is, without normalization by thermo_style custom. You can include a division by “natoms” in the variable formula if this is not the case.

17.123.4 Restrictions

This command must come after the simulation box is defined by a \texttt{read_data}, \texttt{read_restart}, or \texttt{create_box} command.

17.123.5 Related commands

thermo, thermo_modify, fix_modify, compute temp, compute pressure

17.123.6 Default

thermo_style one
17.124  third_order command

17.124.1 Syntax

third_order  group-ID  style  delta  args  keyword  value  ...

- group-ID = ID of group of atoms to displace
- style = regular or eskm
- delta = finite different displacement length (distance units)
- one or more keyword/arg pairs may be appended

  keyword = file or binary
  file name = name of output file for the third order tensor
  binary arg = yes or no or gzip

17.124.2 Examples

third_order  1  regular  0.000001
third_order  1  eskm  0.000001
third_order  3  regular  0.000004  file  third_order.dat
third_order  5  eskm  0.00000001  file  third_order.dat  binary  yes

17.124.3 Description

Calculate the third order force constant tensor by finite difference of the selected group,

\[ \Phi_{ijk}^{\alpha\beta\gamma} = \frac{\partial^3 U}{\partial x_i,\alpha \partial x_j,\beta \partial x_k,\gamma} \]

where Phi is the third order force constant tensor.

The output of the command is the tensor, three elements at a time. The three elements correspond to the three gamma elements for a specific i/alpha/j/beta/k. The initial five numbers are i, alpha, j, beta, and k respectively.

If the style eskm is selected, the tensor will be using energy units of 10 J/mol. These units conform to eskm style from the dynamical_matrix command, which will simplify operations using dynamical matrices with third order tensors.
17.124.4 Restrictions

The command collects a 9 times the number of atoms in the group on every single MPI rank, so the memory requirements can be very significant for large systems.

This command is part of the USER-PHONON package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

17.124.5 Related commands

fix phonon dynamical_matrix

17.124.6 Default

The default settings are file = “third_order.dat”, binary = no

17.125 timer command

17.125.1 Syntax

```
timer args
```

- args = one or more of off or loop or normal or full or sync or nosync or timeout or every

off = do not collect or print any timing information
loop = collect only the total time for the simulation loop
normal = collect timer information broken down by sections (default)
full = like normal but also include CPU and thread utilization
sync = explicitly synchronize MPI tasks between sections
nosync = do not synchronize MPI tasks between sections (default)
timeout elapse = set wall time limit to elapse
every Ncheck = perform timeout check every Ncheck steps

17.125.2 Examples

```
timer full sync
timer timeout 200 every 100
```

17.125.3 Description

Select the level of detail at which LAMMPS performs its CPU timings. Multiple keywords can be specified with the timer command. For keywords that are mutually exclusive, the last one specified takes precedence.

During a simulation run LAMMPS collects information about how much time is spent in different sections of the code and thus can provide information for determining performance and load imbalance problems. This can be done at different levels of detail and accuracy. For more information about the timing output, see the Run output doc page.

The off setting will turn all time measurements off. The loop setting will only measure the total time for a run and not collect any detailed per section information. With the normal setting, timing information for portions of the
timestep (pairwise calculations, neighbor list construction, output, etc) are collected as well as information about load imbalances for those sections across processors. The full setting adds information about CPU utilization and thread utilization, when multi-threading is enabled.

With the sync setting, all MPI tasks are synchronized at each timer call which measures load imbalance for each section more accurately, though it can also slow down the simulation by prohibiting overlapping independent computations on different MPI ranks Using the nosync setting (which is the default) turns this synchronization off.

With the timeout keyword a wall time limit can be imposed, that affects the run and minimize commands. This can be convenient when calculations have to comply with execution time limits, e.g. when running under a batch system when you want to maximize the utilization of the batch time slot, especially for runs where the time per timestep varies much and thus it becomes difficult to predict how many steps a simulation can perform for a given wall time limit. This also applies for difficult to converge minimizations. The timeout elapse value should be somewhat smaller than the maximum wall time requested from the batch system, as there is usually some overhead to launch jobs, and it is advisable to write out a restart after terminating a run due to a timeout.

The timeout timer starts when the command is issued. When the time limit is reached, the run or energy minimization will exit on the next step or iteration that is a multiple of the Ncheck value which can be set with the every keyword. Default is checking every 10 steps. After the timer timeout has expired all subsequent run or minimize commands in the input script will be skipped. The remaining time or timer status can be accessed with the thermo variable timeremain, which will be zero, if the timeout is inactive (default setting), it will be negative, if the timeout time is expired and positive if there is time remaining and in this case the value of the variable are the number of seconds remaining.

When the timeout key word is used a second time, the timer is restarted with a new time limit. The timeout elapse value can be specified as off or unlimited to impose a no timeout condition (which is the default). The elapse setting can be specified as a single number for seconds, two numbers separated by a colon (MM:SS) for minutes and seconds, or as three numbers separated by colons for hours, minutes, and seconds (H:MM:SS).

The every keyword sets how frequently during a run or energy minimization the wall clock will be checked. This check count applies to the outer iterations or time steps during minimizations or r-RESPA runs, respectively. Checking for timeout too often, can slow a calculation down. Checking too infrequently can make the timeout measurement less accurate, with the run being stopped later than desired.

Note: Using the full and sync options provides the most detailed and accurate timing information, but can also have a negative performance impact due to the overhead of the many required system calls. It is thus recommended to use these settings only when testing tests to identify performance bottlenecks. For calculations with few atoms or a very large number of processors, even the normal setting can have a measurable negative performance impact. In those cases you can just use the loop or off setting.

17.126 timestep command

17.126.1 Syntax

```
timestep dt
```

- dt = timestep size (time units)

17.126.2 Examples

```
timestep 2.0

timestep 0.003
```

17.126.3 Description

Set the timestep size for subsequent molecular dynamics simulations. See the `units` command for the time units associated with each choice of units that LAMMPS supports.

The default value for the timestep size also depends on the choice of units for the simulation; see the default values below.

When the `run style` is `respa`, dt is the timestep for the outer loop (largest) timestep.

17.130.1  Syntax

\[ \text{units style} \]

- style = lj or real or metal or si or cgs or electron or micro or nano
17.130.2 Examples

```
units metal
units lj
```

17.130.3 Description

This command sets the style of units used for a simulation. It determines the units of all quantities specified in the input script and data file, as well as quantities output to the screen, log file, and dump files. Typically, this command is used at the very beginning of an input script.

For all units except \(lj\), LAMMPS uses physical constants from www.physics.nist.gov. For the definition of Kcal in real units, LAMMPS uses the thermochemical calorie = 4.184 J.

The choice you make for units simply sets some internal conversion factors within LAMMPS. This means that any simulation you perform for one choice of units can be duplicated with any other unit setting LAMMPS supports. In this context “duplicate” means the particles will have identical trajectories and all output generated by the simulation will be identical. This will be the case for some number of timesteps until round-off effects accumulate, since the conversion factors for two different unit systems are not identical to infinite precision.

To perform the same simulation in a different set of units you must change all the unit-based input parameters in your input script and other input files (data file, potential files, etc) correctly to the new units. And you must correctly convert all output from the new units to the old units when comparing to the original results. That is often not simple to do.

Potential or table files may have a `UNITS:` tag included in the first line indicating the unit style those files were created for. If the tag exists, its value will be compared to the chosen unit style and LAMMPS will stop with an error message if there is a mismatch. In some select cases and for specific combinations of unit styles, LAMMPS is capable of automatically converting potential parameters from a file. In those cases, a warning message signaling that an automatic conversion has happened is printed to the screen.

For style \(lj\), all quantities are unitless. Without loss of generality, LAMMPS sets the fundamental quantities mass, \(\sigma\), \(\epsilon\), and the Boltzmann constant \(k_B = 1\). The masses, distances, energies you specify are multiples of these fundamental values. The formulas relating the reduced or unitless quantity (with an asterisk) to the same quantity with units is also given. Thus you can use the mass \& \(\sigma\) \& \(\epsilon\) values for a specific material and convert the results from a unitless LJ simulation into physical quantities.

- mass = \(m\) or \(m^* = \frac{m}{\sigma}\)
- distance = \(\sigma\), where \(x^* = \frac{x}{\sigma}\)
- time = \(\tau\), where \(\tau^* = \tau \sqrt{m\sigma^2}\)
- energy = \(\epsilon\), where \(E^* = \frac{E}{\epsilon}\)
- velocity = \(\sqrt{\frac{\epsilon}{\sigma}}\), where \(v^* = v\sqrt{\frac{\epsilon}{\sigma}}\)
- force = \(\frac{\epsilon}{\sigma}\), where \(f^* = f\frac{\sigma}{\epsilon}\)
- torque = \(\epsilon\), where \(t^* = \frac{t}{\epsilon}\)
- temperature = reduced LJ temperature, where \(T^* = \frac{Tk_B}{\epsilon}\)
- pressure = reduced LJ pressure, where \(p^* = p\frac{\sigma^3}{\epsilon}\)
- dynamic viscosity = reduced LJ viscosity, where \(\eta^* = \eta\frac{\sigma^3}{\epsilon\tau}\)
- charge = reduced LJ charge, where \(q^* = q\sqrt{\frac{4\pi\epsilon_0}{\sigma\epsilon}}\)
• dipole = reduced LJ dipole, moment where $\mu^* = \mu \sqrt{\frac{1}{4\pi\varepsilon_0\sigma^3}}$

• electric field = force/charge, where $E^* = E \sqrt{\frac{4\pi\varepsilon_0\sigma^3}{\varepsilon}}$

• density = mass/volume, where $\rho^* = \rho \sigma^{dim}$

Note that for LJ units, the default mode of thermodynamic output via the `thermo_style` command is to normalize all extensive quantities by the number of atoms. E.g. potential energy is extensive because it is summed over atoms, so it is output as energy/atom. Temperature is intensive since it is already normalized by the number of atoms, so it is output as-is. This behavior can be changed via the `thermo_modify norm` command.

For style *real*, these are the units:

• mass = grams/mole
• distance = Angstroms
• time = femtoseconds
• energy = Kcal/mole
• velocity = Angstroms/femtosecond
• force = Kcal/mole-Angstrom
• torque = Kcal/mole
• temperature = Kelvin
• pressure = atmospheres
• dynamic viscosity = Poise
• charge = multiple of electron charge (1.0 is a proton)
• dipole = charge*Angstroms
• electric field = volts/Angstrom
• density = gram/cm$^{dim}$

For style *metal*, these are the units:

• mass = grams/mole
• distance = Angstroms
• time = picoseconds
• energy = eV
• velocity = Angstroms/picosecond
• force = eV/Angstrom
• torque = eV
• temperature = Kelvin
• pressure = bars
• dynamic viscosity = Poise
• charge = multiple of electron charge (1.0 is a proton)
• dipole = charge*Angstroms
• electric field = volts/Angstrom
• density = gram/cm$^{dim}$
For style *si*, these are the units:

- mass = kilograms
- distance = meters
- time = seconds
- energy = Joules
- velocity = meters/second
- force = Newtons
- torque = Newton-meters
- temperature = Kelvin
- pressure = Pascals
- dynamic viscosity = Pascal*second
- charge = Coulombs (1.6021765e-19 is a proton)
- dipole = Coulombs*meters
- electric field = volts/meter
- density = kilograms/meter^dim

For style *cgs*, these are the units:

- mass = grams
- distance = centimeters
- time = seconds
- energy = ergs
- velocity = centimeters/second
- force = dynes
- torque = dyne-centimeters
- temperature = Kelvin
- pressure = dyne/cm^2 or barye = 1.0e-6 bars
- dynamic viscosity = Poise
- charge = statcoulombs or esu (4.8032044e-10 is a proton)
- dipole = statcoul-cm = 10^18 debye
- electric field = statvolt/cm or dyne/esu
- density = grams/cm^dim

For style *electron*, these are the units:

- mass = atomic mass units
- distance = Bohr
- time = femtoseconds
- energy = Hartrees
- velocity = Bohr/atomic time units [1.03275e-15 seconds]
• force = Hartrees/Bohr
• temperature = Kelvin
• pressure = Pascals
• charge = multiple of electron charge (1.0 is a proton)
• dipole moment = Debye
• electric field = volts/cm

For style micro, these are the units:
• mass = picograms
• distance = micrometers
• time = microseconds
• energy = picogram-micrometer^2/microsecond^2
• velocity = micrometers/microsecond
• force = picogram-micrometer/microsecond^2
• torque = picogram-micrometer^2/microsecond^2
• temperature = Kelvin
• pressure = picogram/(micrometer-microsecond^2)
• dynamic viscosity = picogram/(micrometer-microsecond)
• charge = picocoulombs (1.6021765e-7 is a proton)
• dipole = picocoulomb-micrometer
• electric field = volt/micrometer
• density = picograms/micrometer^dim

For style nano, these are the units:
• mass = attograms
• distance = nanometers
• time = nanoseconds
• energy = attogram-nanometer^2/nanosecond^2
• velocity = nanometers/nanosecond
• force = attogram-nanometer/nanosecond^2
• torque = attogram-nanometer^2/nanosecond^2
• temperature = Kelvin
• pressure = attogram/(nanometer-nanosecond^2)
• dynamic viscosity = attogram/(nanometer-nanosecond)
• charge = multiple of electron charge (1.0 is a proton)
• dipole = charge-nanometer
• electric field = volt/nanometer
• density = attograms/nanometer^dim
The units command also sets the timestep size and neighbor skin distance to default values for each style:

- For style `lj` these are $dt = 0.005 \tau$ and $\text{skin} = 0.3 \sigma$.
- For style `real` these are $dt = 1.0$ femtoseconds and $\text{skin} = 2.0$ Angstroms.
- For style `metal` these are $dt = 0.001$ picoseconds and $\text{skin} = 2.0$ Angstroms.
- For style `si` these are $dt = 1.0e-8$ seconds and $\text{skin} = 0.001$ meters.
- For style `cgs` these are $dt = 1.0e-8$ seconds and $\text{skin} = 0.1$ centimeters.
- For style `electron` these are $dt = 0.001$ femtoseconds and $\text{skin} = 2.0$ Bohr.
- For style `micro` these are $dt = 2.0$ microseconds and $\text{skin} = 0.1$ micrometers.
- For style `nano` these are $dt = 0.00045$ nanoseconds and $\text{skin} = 0.1$ nanometers.

### 17.130.4 Restrictions

17.131.3 Description

This command assigns one or more strings to a variable name for evaluation later in the input script or during a simulation.

Variables can thus be useful in several contexts. A variable can be defined and then referenced elsewhere in an input script to become part of a new input command. For variable styles that store multiple strings, the next command can be used to increment which string is assigned to the variable. Variables of style equal store a formula which when evaluated produces a single numeric value which can be output either directly (see the print, fix print, and run every commands) or as part of thermodynamic output (see the thermo_style command), or used as input to an averaging fix (see the fix ave/time command). Variables of style vector store a formula which produces a vector of such values which can be used as input to various averaging fixes, or elements of which can be part of thermodynamic output. Variables of style atom store a formula which when evaluated produces one numeric value per atom which can be output to a dump file (see the dump custom command) or used as input to an averaging fix (see the fix ave/chunk and fix ave/atom commands). Variables of style atomfile can be used anywhere in an input script that atom-style variables are used; they get their per-atom values from a file rather than from a formula. Variables of style python can be hooked to Python functions using code you provide, so that the variable gets its value from the evaluation of the Python code. Variables of style internal are used by a few commands which set their value directly.

Note: As discussed on the Commands parse doc page, an input script can use “immediate” variables, specified as $(formula) with parenthesis, where the formula has the same syntax as equal-style variables described on this page. This is a convenient way to evaluate a formula immediately without using the variable command to define a named variable and then evaluate that variable. See below for a more detailed discussion of this feature.

In the discussion that follows, the “name” of the variable is the arbitrary string that is the first argument in the variable command. This name can only contain alphanumeric characters and underscores. The “string” is one or more of the subsequent arguments. The “string” can be simple text as in the first example above, it can contain other variables as in the second example, or it can be a formula as in the third example. The “value” is the numeric quantity resulting
from evaluation of the string. Note that the same string can generate different values when it is evaluated at different times during a simulation.

**Note:** When an input script line is encountered that defines a variable of style *equal* or *vector* or *atom* or *python* that contains a formula or Python code, the formula is NOT immediately evaluated. It will be evaluated every time when the variable is used instead. If you simply want to evaluate a formula in place you can use as so-called. See the section below about “Immediate Evaluation of Variables” for more details on the topic. This is also true of a *format* style variable since it evaluates another variable when it is invoked.

Variables of style *equal* and *vector* and *atom* can be used as inputs to various other commands which evaluate their formulas as needed, e.g. at different timesteps during a run.

Variables of style *internal* can be used in place of an equal-style variable, except by commands that set the value stored by the internal-style variable. Thus any command that states it can use an equal-style variable as an argument, can also use an internal-style variable. This means that when the command evaluates the variable, it will use the value set (internally) by another command.

Variables of style *python* can be used in place of an equal-style variable so long as the associated Python function, as defined by the *python* command, returns a numeric value. Thus any command that states it can use an equal-style variable as an argument, can also use such a python-style variable. This means that when the LAMMPS command evaluates the variable, the Python function will be executed.

**Note:** When a variable command is encountered in the input script and the variable name has already been specified, the command is ignored. This means variables can NOT be re-defined in an input script (with two exceptions, read further). This is to allow an input script to be processed multiple times without resetting the variables; see the *jump* or *include* commands. It also means that using the command-line switch -var will override a corresponding index variable setting in the input script.

There are two exceptions to this rule. First, variables of style *string*, *getenv*, *internal*, *equal*, *vector*, *atom*, and *python* ARE redefined each time the command is encountered. This allows these style of variables to be redefined multiple times in an input script. In a loop, this means the formula associated with an *equal* or *atom* style variable can change if it contains a substitution for another variable, e.g. $x$ or $v_x$.

Second, as described below, if a variable is iterated on to the end of its list of strings via the *next* command, it is removed from the list of active variables, and is thus available to be re-defined in a subsequent variable command. The delete style does the same thing.

The *Commands parse* doc page explains how occurrences of a variable name in an input script line are replaced by the variable’s string. The variable name can be referenced as $x$ if the name “$x$” is a single character, or as $\{\text{LoopVar}\}$ if the name “LoopVar” is one or more characters.

As described below, for variable styles *index*, *loop*, *file*, *universe*, and *uloop*, which string is assigned to a variable can be incremented via the *next* command. When there are no more strings to assign, the variable is exhausted and a flag is set that causes the next *jump* command encountered in the input script to be skipped. This enables the construction of simple loops in the input script that are iterated over and then exited from.

As explained above, an exhausted variable can be re-used in an input script. The delete style also removes the variable, the same as if it were exhausted, allowing it to be redefined later in the input script or when the input script is looped over. This can be useful when breaking out of a loop via the *if* and *jump* commands before the variable would become exhausted. For example,

```
label loop
variable a loop 5
```

(continues on next page)
This section describes how all the various variable styles are defined and what they store. Except for the `equal` and `vector` and `atom` styles, which are explained in the next section.

Many of the styles store one or more strings. Note that a single string can contain spaces (multiple words), if it is enclosed in quotes in the variable command. When the variable is substituted for in another input script command, its returned string will then be interpreted as multiple arguments in the expanded command.

For the `index` style, one or more strings are specified. Initially, the first string is assigned to the variable. Each time a `next` command is used with the variable name, the next string is assigned. All processors assign the same string to the variable.

Index style variables with a single string value can also be set by using the `command-line switch -var`.

The `loop` style is identical to the `index` style except that the strings are the integers from 1 to N inclusive, if only one argument N is specified. This allows generation of a long list of runs (e.g. 1000) without having to list N strings in the input script. Initially, the string “1” is assigned to the variable. Each time a `next` command is used with the variable name, the next string (“2”, “3”, etc) is assigned. All processors assign the same string to the variable. The `loop` style can also be specified with two arguments N1 and N2. In this case the loop runs from N1 to N2 inclusive, and the string N1 is initially assigned to the variable. N1 <= N2 and N2 >= 0 is required.

For the `world` style, one or more strings are specified. There must be one string for each processor partition or “world”. LAMMPS can be run with multiple partitions via the `-partition command-line switch`. This variable command assigns one string to each world. All processors in the world are assigned the same string. The next command cannot be used with `equal` style variables, since there is only one value per world. This style of variable is useful when you wish to run different simulations on different partitions, or when performing a parallel tempering simulation (see the `temper` command), to assign different temperatures to different partitions.

For the `universe` style, one or more strings are specified. There must be at least as many strings as there are processor partitions or “worlds”. LAMMPS can be run with multiple partitions via the `-partition command-line switch`. This variable command initially assigns one string to each world. When a `next` command is encountered using this variable, the first processor partition to encounter it, is assigned the next available string. This continues until all the variable strings are consumed. Thus, this command can be used to run 50 simulations on 8 processor partitions. The simulations will be run one after the other on whatever partition becomes available, until they are all finished. Universe style variables are incremented using the files “tmp.lammps.variable” and “tmp.lammps.variable.lock” which you will see in your directory during such a LAMMPS run.

The `uloop` style is identical to the `universe` style except that the strings are the integers from 1 to N. This allows generation of long list of runs (e.g. 1000) without having to list N strings in the input script.

For the `string` style, a single string is assigned to the variable. Two differences between this style and using the `index` style exist: a variable with `string` style can be redefined, e.g. by another command later in the input script, or if the script is read again in a loop. The other difference is that `string` performs variable substitution even if the string parameter is quoted.

For the `format` style, an equal-style variable is specified along with a C-style format string, e.g. “%f” or “%.10g”, which must be appropriate for formatting a double-precision floating-point value. The default format is “%.15g”. This variable style allows an equal-style variable to be formatted precisely when it is evaluated.
If you simply wish to print a variable value with desired precision to the screen or logfile via the `print` or `fix print` commands, you can also do this by specifying an “immediate” variable with a trailing colon and format string, as part of the string argument of those commands. This is explained on the `Commands parse` doc page.

For the `getenv` style, a single string is assigned to the variable which should be the name of an environment variable. When the variable is evaluated, it returns the value of the environment variable, or an empty string if it is not defined. This style of variable can be used to adapt the behavior of LAMMPS input scripts via environment variable settings, or to retrieve information that has been previously stored with the `shell putenv` command. Note that because environment variable settings are stored by the operating systems, they persist beyond a `clear` command.

For the `file` style, a filename is provided which contains a list of strings to assign to the variable, one per line. The strings can be numeric values if desired. See the discussion of the `next()` function below for equal-style variables, which will convert the string of a file-style variable into a numeric value in a formula.

When a file-style variable is defined, the file is opened and the string on the first line is read and stored with the variable. This means the variable can then be evaluated as many times as desired and will return that string. There are two ways to cause the next string from the file to be read: use the `next` command or the `next()` function in an equal- or atom-style variable, as discussed below.

The rules for formatting the file are as follows. A comment character “#” can be used anywhere on a line; text starting with the comment character is stripped. Blank lines are skipped. The first “word” of a non-blank line, delimited by white-space, is the “string” assigned to the variable.

For the `atomfile` style, a filename is provided which contains one or more sets of values, to assign on a per-atom basis to the variable. The format of the file is described below.

When an atomfile-style variable is defined, the file is opened and the first set of per-atom values are read and stored with the variable. This means the variable can then be evaluated as many times as desired and will return those values. There are two ways to cause the next set of per-atom values from the file to be read: use the `next` command or the `next()` function in an atom-style variable, as discussed below.

The rules for formatting the file are as follows. Each time a set of per-atom values is read, a non-blank line is searched for in the file. A comment character “#” can be used anywhere on a line; text starting with the comment character is stripped. Blank lines are skipped. The first “word” of a non-blank line, delimited by white-space, is read as the count N of per-atom lines to immediately follow. N can be the total number of atoms in the system, or only a subset. The next N lines have the following format

```
ID value
```

where ID is an atom ID and value is the per-atom numeric value that will be assigned to that atom. IDs can be listed in any order.

Note: Every time a set of per-atom lines is read, the value for all atoms is first set to 0.0. Thus values for atoms whose ID does not appear in the set, will remain 0.0.

For the `python` style a Python function name is provided. This needs to match a function name specified in a `python` command which returns a value to this variable as defined by its `return` keyword. For example these two commands would be self-consistent:

```
variable foo python myMultiply
python myMultiply return v_foo format f file funcs.py
```

The two commands can appear in either order so long as both are specified before the Python function is invoked for the first time.

Each time the variable is evaluated, the associated Python function is invoked, and the value it returns is also returned by the variable. Since the Python function can use other LAMMPS variables as input, or query internal LAMMPS quantities to perform its computation, this means the variable can return a different value each time it is evaluated.
The type of value stored in the variable is determined by the *format* keyword of the *python* command. It can be an integer (i), floating point (f), or string (s) value. As mentioned above, if it is a numeric value (integer or floating point), then the python-style variable can be used in place of an equal-style variable anywhere in an input script, e.g. as an argument to another command that allows for equal-style variables.

For the *internal* style a numeric value is provided. This value will be assigned to the variable until a LAMMPS command sets it to a new value. There are currently only two LAMMPS commands that require *internal* variables as inputs, because they reset them: *create_atoms* and *fix controller*. As mentioned above, an internal-style variable can be used in place of an equal-style variable anywhere else in an input script, e.g. as an argument to another command that allows for equal-style variables.

For the *equal* and *vector* and *atom* styles, a single string is specified which represents a formula that will be evaluated afresh each time the variable is used. If you want spaces in the string, enclose it in double quotes so the parser will treat it as a single argument. For *equal*-style variables the formula computes a scalar quantity, which becomes the value of the variable whenever it is evaluated. For *vector*-style variables the formula must compute a vector of quantities, which becomes the value of the variable whenever it is evaluated. The calculated vector can be on length one, but it cannot be a simple scalar value like that produced by an equal-style compute. I.e. the formula for a vector-style variable must have at least one quantity in it that refers to a global vector produced by a compute, fix, or other vector-style variable. For *atom*-style variables the formula computes one quantity for each atom whenever it is evaluated.

Note that *equal*, *vector*, and *atom* variables can produce different values at different stages of the input script or at different times during a run. For example, if an *equal* variable is used in a *fix print* command, different values could be printed each timestep it was invoked. If you want a variable to be evaluated immediately, so that the result is stored by the variable instead of the string, see the section below on “Immediate Evaluation of Variables”.

The next command cannot be used with *equal* or *vector* or *atom* style variables, since there is only one string.

The formula for an *equal*, *vector*, or *atom* variable can contain a variety of quantities. The syntax for each kind of quantity is simple, but multiple quantities can be nested and combined in various ways to build up formulas of arbitrary complexity. For example, this is a valid (though strange) variable formula:

```
variable x equal "pe + c_MyTemp / vol^(1/3)"
```

Specifically, a formula can contain numbers, constants, thermo keywords, math operators, math functions, group functions, region functions, atom values, atom vectors, compute references, fix references, and references to other variables.

Most of the formula elements produce a scalar value. Some produce a global or per-atom vector of values. Global vectors can be produced by computes or fixes or by other vector-style variables. Per-atom vectors are produced by atom vectors, compute references that represent a per-atom vector, fix references that represent a per-atom vector, and variables that are atom-style variables. Math functions that operate on scalar values produce a scalar value; math function that operate on global or per-atom vectors do so element-by-element and produce a global or per-atom vector.

A formula for equal-style variables cannot use any formula element that produces a global or per-atom vector. A formula for a vector-style variable can use formula elements that produce either a scalar value or a global vector value, but cannot use a formula element that produces a per-atom vector. A formula for an atom-style variable can use formula elements that produce either a scalar value or a per-atom vector, but not one that produces a global vector. Atom-style variables are evaluated by other commands that define a group on which they operate, e.g. a dump or compute or fix command. When they invoke the atom-style variable, only atoms in the group are included in the formula evaluation.
The variable evaluates to 0.0 for atoms not in the group.

**Numbers, constants, and thermo keywords**

Numbers can contain digits, scientific notation (3.0e20,3.0e-20,3.0E20,3.0E-20), and leading minus signs.

Constants are set at compile time and cannot be changed. \( PI \) will return the number 3.14159265358979323846; \( on \), \( true \) or \( yes \) will return 1.0; \( off \), \( false \) or \( no \) will return 0.0; \( version \) will return a numeric version code of the current LAMMPS version (e.g. version 2 Sep 2015 will return the number 20150902). The corresponding value for newer versions of LAMMPS will be larger, for older versions of LAMMPS will be smaller. This can be used to have input scripts adapt automatically to LAMMPS versions, when non-backwards compatible syntax changes are introduced. Here is an illustrative example (which will not work, since the \( version \) has been introduced more recently):

\[
\text{if } $(\text{version}<20140513) \text{ then "communicate vel yes" else "comm_modify vel yes"}$
\]

The thermo keywords allowed in a formula are those defined by the \texttt{thermo_style custom} command. Thermo keywords that require a \texttt{compute} to calculate their values such as \texttt{"temp"} or \texttt{"press"}, use computes stored and invoked by the \texttt{thermo_style} command. This means that you can only use those keywords in a variable if the style you are using with the \texttt{thermo_style} command (and the thermo keywords associated with that style) also define and use the needed compute. Note that some thermo keywords use a compute indirectly to calculate their value (e.g. the enthalpy keyword uses temp, pe, and pressure). If a variable is evaluated directly in an input script (not during a run), then the values accessed by the thermo keyword must be current. See the discussion below about “Variable Accuracy”.

**Math Operators**

Math operators are written in the usual way, where the “\(x\)” and “\(y\)” in the examples can themselves be arbitrarily complex formulas, as in the examples above. In this syntax, “\(x\)” and “\(y\)” can be scalar values or per-atom vectors. For example, “\(ke/natoms\)” is the division of two scalars, where “\(vy+vz\)” is the element-by-element sum of two per-atom vectors of y and z velocities.

Operators are evaluated left to right and have the usual C-style precedence: unary minus and unary logical NOT operator “!” have the highest precedence, exponentiation “^” is next; multiplication and division and the modulo operator “\%” are next; addition and subtraction are next; the 4 relational operators “<”, “<=”, “>”, and “>=” are next; the two remaining relational operators “==” and “!=” are next; then the logical AND operator “&&”; and finally the logical OR operator (“||” and logical XOR (exclusive or) operator “\(^\wedge\)” have the lowest precedence. Parenthesis can be used to group one or more portions of a formula and/or enforce a different order of evaluation than what would occur with the default precedence.

**Note:** Because a unary minus is higher precedence than exponentiation, the formula “\(-2^2\)” will evaluate to 4, not -4. This convention is compatible with some programming languages, but not others. As mentioned, this behavior can be easily overridden with parenthesis; the formula “\(-桃花(2^2)\)” will evaluate to -4.

The 6 relational operators return either a 1.0 or 0.0 depending on whether the relationship between \(x\) and \(y\) is TRUE or FALSE. For example the expression \(x<10.0\) in an atom-style variable formula will return 1.0 for all atoms whose \(x\)-coordinate is less than 10.0, and 0.0 for the others. The logical AND operator will return 1.0 if both its arguments are non-zero, else it returns 0.0. The logical OR operator will return 1.0 if either of its arguments is non-zero, else it returns 0.0. The logical XOR operator will return 1.0 if one of its arguments is zero and the other non-zero, else it returns 0.0. The logical NOT operator returns 1.0 if its argument is 0.0, else it returns 0.0.
These relational and logical operators can be used as a masking or selection operation in a formula. For example, the number of atoms whose properties satisfy one or more criteria could be calculated by taking the returned per-atom vector of ones and zeroes and passing it to the `compute reduce` command.

**Math Functions**

Math functions are specified as keywords followed by one or more parenthesized arguments “x”, “y”, “z”, each of which can themselves be arbitrarily complex formulas. In this syntax, the arguments can represent scalar values or global vectors or per-atom vectors. In the latter case, the math operation is performed on each element of the vector. For example, “sqrt(natoms)” is the sqrt() of a scalar, where “sqrt(y*z)” yields a per-atom vector with each element being the sqrt() of the product of one atom’s y and z coordinates.

Most of the math functions perform obvious operations. The ln() is the natural log; log() is the base 10 log.

The `random(x,y,z)` function takes 3 arguments: x = lo, y = hi, and z = seed. It generates a uniform random number between lo and hi. The `normal(x,y,z)` function also takes 3 arguments: x = mu, y = sigma, and z = seed. It generates a Gaussian variate centered on mu with variance sigma^2. In both cases the seed is used the first time the internal random number generator is invoked, to initialize it. For equal-style and vector-style variables, every processor uses the same seed so that they each generate the same sequence of random numbers. For atom-style variables, a unique seed is created for each processor, based on the specified seed. This effectively generates a different random number for each atom being looped over in the atom-style variable.

**Note:** Internally, there is just one random number generator for all equal-style and vector-style variables and another one for all atom-style variables. If you define multiple variables (of each style) which use the random() or normal() math functions, then the internal random number generators will only be initialized once, which means only one of the specified seeds will determine the sequence of generated random numbers.

The ceil(), floor(), and round() functions are those in the C math library. Ceil() is the smallest integer not less than its argument. Floor() if the largest integer not greater than its argument. Round() is the nearest integer to its argument.

The `ramp(x,y)` function uses the current timestep to generate a value linearly interpolated between the specified x,y values over the course of a run, according to this formula:

\[
\text{value} = x + (y-x) \times \frac{\text{timestep-startstep}}{\text{stopstep-startstep}}
\]

The run begins on startstep and ends on stopstep. Startstep and stopstep can span multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

The `stagger(x,y)` function uses the current timestep to generate a new timestep. X,y > 0 and x > y are required. The generated timesteps increase in a staggered fashion, as the sequence x,x+y,2x,2x+y,3x,3x+y,etc. For any current timestep, the next timestep in the sequence is returned. Thus if stagger(1000,100) is used in a variable by the `dump_modify every` command, it will generate the sequence of output timesteps:

\[100,1000,1100,2000,2100,3000,\text{etc}\]

The `logfreq(x,y,z)` function uses the current timestep to generate a new timestep. X,y,z > 0 and y < z are required. The generated timesteps are on a base-z logarithmic scale, starting with x, and the y value is how many of the z-1 possible timesteps within one logarithmic interval are generated. I.e. the timesteps follow the sequence x,2x,3x,...y*x,x*z,2x*z,3x*z,...y*x*z,x*z^2,2x*z^2,etc. For any current timestep, the next timestep in the sequence is returned. Thus if logfreq(100,4,10) is used in a variable by the `dump_modify every` command, it will generate this sequence of output timesteps:

\[100,200,300,400,1000,2000,3000,4000,10000,20000,\text{etc}\]
The logfreq2(x,y,z) function is similar to logfreq, except a single logarithmic interval is divided into y equally-spaced timesteps and all of them are output. Y < z is not required. Thus, if logfreq2(100,18,10) is used in a variable by the dump_modify every command, then the interval between 100 and 1000 is divided as 900/18 = 50 steps, and it will generate the sequence of output timesteps:

100,150,200,...950,1000,1500,2000,...9500,10000,15000,etc

The logfreq3(x,y,z) function generates y points between x and z (inclusive), that are separated by a multiplicative ratio: \((z/x)^{1/(y-1)}\). Constraints are: x,z > 0, y > 1, z-x >= y-1. For eg., if logfreq3(10,25,1000) is used in a variable by the fix print command, then the interval between 10 and 1000 is divided into 24 parts with a multiplicative separation of ~1.21, and it will generate the following sequence of output timesteps:

10, 13, 15, 18, 22, 27, 32,...384, 465, 563, 682, 826, 1000

The stride(x,y,z) function uses the current timestep to generate a new timestep. X,y >= 0 and z > 0 and x <= y are required. The generated timesteps increase in increments of z, from x to y, i.e. it generates the sequence x,x+z,x+2z,...,y. If y-x is not a multiple of z, then similar to the way a for loop operates, the last value will be one that does not exceed y. For any current timestep, the next timestep in the sequence is returned. Thus if stride(1000,2000,100) is used in a variable by the dump_modify every command, it will generate the sequence of output timesteps:

1000,1100,1200, ... ,1900,2000

The stride2(x,y,z,a,b,c) function is similar to the stride() function except it generates two sets of strided timesteps, one at a coarser level and one at a finer level. Thus it is useful for debugging, e.g. to produce output every timestep at the point in simulation when a problem occurs. X,y >= 0 and z > 0 and x <= y are required, as are a,b >= 0 and c > 0 and a < b. Also, a >= x and b <= y are required so that the second stride is inside the first. The generated timesteps increase in increments of z, starting at x, until a is reached. At that point the timestep increases in increments of c, from a to b, then after b, increments by z are resumed until y is reached. For any current timestep, the next timestep in the sequence is returned. Thus if stride2(1000,2000,100,1350,1360,1) is used in a variable by the dump_modify every command, it will generate the sequence of output timesteps:

1000,1100,1200,1300,1350,1351,1352, ... 1359,1360,1400,1500, ... ,2000

The vdisplace(x,y) function takes 2 arguments: x = value0 and y = velocity, and uses the elapsed time to change the value by a linear displacement due to the applied velocity over the course of a run, according to this formula:

\[ \text{value} = \text{value0 + velocity} \times (\text{timestep-startstep}) \times \text{dt} \]

where dt = the timestep size.

The run begins on startstep. Startstep can span multiple runs, using the start keyword of the run command. See the run command for details of how to do this. Note that the thermo_style keyword elaplong = timestep-startstep.

The swiggle(x,y,z) and cwiggle(x,y,z) functions each take 3 arguments: x = value0, y = amplitude, z = period. They use the elapsed time to oscillate the value by a sin() or cos() function over the course of a run, according to one of these formulas, where omega = 2 PI / period:

\[ \text{value} = \text{value0 + Amplitude} \times \sin(\omega \times (\text{timestep-startstep}) \times \text{dt}) \]
\[ \text{value} = \text{value0 + Amplitude} \times (1 - \cos(\omega \times (\text{timestep-startstep}) \times \text{dt})) \]

where dt = the timestep size.

The run begins on startstep. Startstep can span multiple runs, using the start keyword of the run command. See the run command for details of how to do this. Note that the thermo_style keyword elaplong = timestep-startstep.
Group and Region Functions

Group functions are specified as keywords followed by one or two parenthesized arguments. The first argument $ID$ is the group-ID. The $dim$ argument, if it exists, is $x$ or $y$ or $z$. The $dir$ argument, if it exists, is $xmin$, $xmax$, $ymin$, $ymax$, $zmin$, or $zmax$. The $dimdim$ argument, if it exists, is $xx$ or $yy$ or $zz$ or $xy$ or $yz$ or $xz$.

The group function count() is the number of atoms in the group. The group functions mass() and charge() are the total mass and charge of the group. Xcm() and vcm() return components of the position and velocity of the center of mass of the group. Fcm() returns a component of the total force on the group of atoms. Bound() returns the min/max of a particular coordinate for all atoms in the group. Gyration() computes the radius-of-gyration of the group of atoms. See the compute gyration command for a definition of the formula. Angmom() returns components of the angular momentum of the group of atoms around its center of mass. Torque() returns components of the torque on the group of atoms around its center of mass, based on current forces on the atoms. Inertia() returns one of 6 components of the symmetric inertia tensor of the group of atoms around its center of mass, ordered as $I_{xx}, I_{yy}, I_{zz}, I_{xy}, I_{yz}, I_{xz}$. Omega() returns components of the angular velocity of the group of atoms around its center of mass.

Region functions are specified exactly the same way as group functions except they take an extra final argument $IDR$ which is the region ID. The function is computed for all atoms that are in both the group and the region. If the group is “all”, then the only criteria for atom inclusion is that it be in the region.

Special Functions

Special functions take specific kinds of arguments, meaning their arguments cannot be formulas themselves.

The $sum(x)$, $min(x)$, $max(x)$, $ave(x)$, $trap(x)$, and $slope(x)$ functions each take 1 argument which is of the form “c_ID” or “c_ID[N]” or “f_ID” or “f_ID[N]” or “v_name”. The first two are computes and the second two are fixes; the ID in the reference should be replaced by the ID of a compute or fix defined elsewhere in the input script. The compute or fix must produce either a global vector or array. If it produces a global vector, then the notation without “[N]” should be used. If it produces a global array, then the notation with “[N]” should be used, when $N$ is an integer, to specify which column of the global array is being referenced. The last form of argument “v_name” is for a vector-style variable where “name” is replaced by the name of the variable.

These functions operate on a global vector of inputs and reduce it to a single scalar value. This is analogous to the operation of the compute reduce command, which performs similar operations on per-atom and local vectors.

The sum() function calculates the sum of all the vector elements. The min() and max() functions find the minimum and maximum element respectively. The ave() function is the same as sum() except that it divides the result by the length of the vector.

The trap() function is the same as sum() except the first and last elements are multiplied by a weighting factor of 1/2 when performing the sum. This effectively implements an integration via the trapezoidal rule on the global vector of data. I.e. consider a set of points, equally spaced by 1 in their x coordinate: $(1, V_1), (2, V_2), \ldots, (N, V_N)$, where the $V_i$ are the values in the global vector of length $N$. The integral from 1 to $N$ of these points is trap(). When appropriately normalized by the timestep size, this function is useful for calculating integrals of time-series data, like that generated by the fix ave/correlate command.

The slope() function uses linear regression to fit a line to the set of points, equally spaced by 1 in their x coordinate: $(1, V_1), (2, V_2), \ldots, (N, V_N)$, where the $V_i$ are the values in the global vector of length $N$. The returned value is the slope of the line. If the line has a single point or is vertical, it returns 1.0e20.

The gmask(x) function takes 1 argument which is a group ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in the group, and a 0 for atoms that are not.

The rmask(x) function takes 1 argument which is a region ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in the geometric region, and a 0 for atoms that are not.
The `grmask(x,y)` function takes 2 arguments. The first is a group ID, and the second is a region ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in both the group and region, and a 0 for atoms that are not in both.

The `next(x)` function takes 1 argument which is a variable ID (not “v_foo”, just “foo”). It must be for a file-style or atomfile-style variable. Each time the `next()` function is invoked (i.e. each time the equal-style or atom-style variable is evaluated), the following steps occur.

For file-style variables, the current string value stored by the file-style variable is converted to a numeric value and returned by the function. And the next string value in the file is read and stored. Note that if the line previously read from the file was not a numeric string, then it will typically evaluate to 0.0, which is likely not what you want.

For atomfile-style variables, the current per-atom values stored by the atomfile-style variable are returned by the function. And the next set of per-atom values in the file is read and stored.

Since file-style and atomfile-style variables read and store the first line of the file or first set of per-atoms values when they are defined in the input script, these are the value(s) that will be returned the first time the `next()` function is invoked. If `next()` is invoked more times than there are lines or sets of lines in the file, the variable is deleted, similar to how the `next` command operates.

**Feature Functions**

Feature functions allow to probe the running LAMMPS executable for whether specific features are either active, defined, or available. The functions take two arguments, a category and a corresponding argument. The arguments are strings thus cannot be formulas themselves (only $-style immediate variable expansion is possible). Return value is either 1.0 or 0.0 depending on whether the function evaluates to true or false, respectively.

The `is_active()` function allows to query for active settings which are grouped by categories. Currently supported categories and arguments are:

- `package` (argument = `gpu` or `intel` or `kokkos` or `omp`)
- `newton` (argument = `pair` or `bond` or `any`)
- `pair` (argument = `single` or `respa` or `manybody` or `tail` or `shift`)
- `comm_style` (argument = `brick` or `tiled`)
- `min_style` (argument = any of the compiled in minimizer styles)
- `run_style` (argument = any of the compiled in run styles)
- `atom_style` (argument = any of the compiled in atom styles)
- `pair_style` (argument = any of the compiled in pair styles)
- `bond_style` (argument = any of the compiled in bond styles)
- `angle_style` (argument = any of the compiled in angle styles)
- `dihedral_style` (argument = any of the compiled in dihedral styles)
- `improper_style` (argument = any of the compiled in improper styles)
- `kspace_style` (argument = any of the compiled in kspace styles)

Most of the settings are self-explanatory, the `single` argument in the `pair` category allows to check whether a pair style supports a Pair::single() function as needed by compute group/group and others features or LAMMPS, `respa` allows to check whether the inner/middle/outer mode of r-RESPA is supported. In the various style categories, the checking is also done using suffix flags, if available and enabled.
Example 1: disable use of suffix for ppm when using GPU package (i.e. run it on the CPU concurrently to running the pair style on the GPU), but do use the suffix otherwise (e.g. with USER-OMP).

```
pair_style lj/cut/coul/long 14.0
if $(is_active(package,gpu)) then "suffix off"
kspace_style ppm
```

Example 2: use $r$-RESPA with inner/outer cutoff, if supported by pair style, otherwise fall back to using pair and reducing the outer time step.

```
timestep $(2.0*(1.0+2.0*is_active(pair,respa))
if $(is_active(pair,respa)) then "run_style respa 4 3 2 2 improper 1 inner 2 5.5 7.0
    outer 3 kspace 4" else "run_style respa 3 3 2 improper 1 pair 2 kspace 3"
```

The `is_defined()` function allows to query categories like `compute`, `dump`, `fix`, `group`, `region`, and `variable` whether an entry with the provided name or id is defined.

The `is_available(category,name)` function allows to query whether a specific optional feature is available, i.e. compiled in. This currently works for the following categories: command, compute, fix, pair_style and feature. For all categories except command and feature also appending active suffixes is tried before reporting failure.

The `feature` category is used to check the availability of compiled in features such as GZIP support, PNG support, JPEG support, FFmpeg support, and C++ exceptions for error handling. Corresponding values for name are `gzip`, `png`, `jpeg`, `ffmpeg` and `exceptions`.

This enables writing input scripts which only dump using a given format if the compiled binary supports it.

```
if "$(is_available(feature,png))" then "print 'PNG supported'" else "print 'PNG not supported'"
if "$(is_available(feature,ffmpeg)" then "dump 3 all movie 25 movie.mp4 type type
    zoom 1.6 adiam 1.0"
```

Atom Values and Vectors

Atom values take an integer argument I from 1 to N, where I is the atom-ID, e.g. x[243], which means use the x coordinate of the atom with ID = 243. Or they can take a variable name, specified as v_name, where name is the name of the variable, like x[v_myIndex]. The variable can be of any style except vector or atom or atomfile variables. The variable is evaluated and the result is expected to be numeric and is cast to an integer (i.e. 3.4 becomes 3), to use an index, which must be a value from 1 to N. Note that a “formula” cannot be used as the argument between the brackets, e.g. x[243+10] or x[v_myIndex+1] are not allowed. To do this a single variable can be defined that contains the needed formula.

Note that the 0 < atom-ID <= N, where N is the largest atom ID in the system. If an ID is specified for an atom that does not currently exist, then the generated value is 0.0.

Atom vectors generate one value per atom, so that a reference like “vx” means the x-component of each atom’s velocity will be used when evaluating the variable.

The meaning of the different atom values and vectors is mostly self-explanatory. Mol refers to the molecule ID of an atom, and is only defined if an atom_style is being used that defines molecule IDs.

Note that many other atom attributes can be used as inputs to a variable by using the compute property/atom command and then specifying a quantity from that compute.
Compute References

Compute references access quantities calculated by a `compute`. The ID in the reference should be replaced by the ID of a compute defined elsewhere in the input script. As discussed in the doc page for the `compute` command, computes can produce global, per-atom, or local values. Only global and per-atom values can be used in a variable. Computes can also produce a scalar, vector, or array.

An equal-style variable can only use scalar values, which means a global scalar, or an element of a global or per-atom vector or array. A vector-style variable can use scalar values or a global vector of values, or a column of a global array of values. Atom-style variables can use global scalar values. They can also use per-atom vector values, or a column of a per-atom array. See the doc pages for individual computes to see what kind of values they produce.

Examples of different kinds of compute references are as follows. There is typically no ambiguity (see exception below) as to what a reference means, since computes only produce either global or per-atom quantities, never both.

<table>
<thead>
<tr>
<th>c_ID</th>
<th>global scalar, or per-atom vector</th>
</tr>
</thead>
<tbody>
<tr>
<td>c_ID[I]</td>
<td>Ith element of global vector, or atom I’s value in per-atom vector, or Ith column from per-atom array</td>
</tr>
<tr>
<td>c_ID[I][J]</td>
<td>I,J element of global array, or atom I’s Jth value in per-atom array</td>
</tr>
</tbody>
</table>

For I and J indices, integers can be specified or a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for the “Atom Values and Vectors” discussion above.

One source of ambiguity for compute references is when a vector-style variable refers to a compute that produces both a global scalar and a global vector. Consider a compute with ID “foo” that does this, referenced as follows by variable “a”, where “myVec” is another vector-style variable:

```
variable a vector c_foo*v_myVec
```

The reference “c_foo” could refer to either the global scalar or global vector produced by compute “foo”. In this case, “c_foo” will always refer to the global scalar, and “C_foo” can be used to reference the global vector. Similarly if the compute produces both a global vector and global array, then “c_foo[I]” will always refer to an element of the global vector, and “C_foo[I]” can be used to reference the Ith column of the global array.

Note that if a variable containing a compute is evaluated directly in an input script (not during a run), then the values accessed by the compute must be current. See the discussion below about “Variable Accuracy”.

Fix References

Fix references access quantities calculated by a `fix`. The ID in the reference should be replaced by the ID of a fix defined elsewhere in the input script. As discussed in the doc page for the `fix` command, fixes can produce global, per-atom, or local values. Only global and per-atom values can be used in a variable. Fixes can also produce a scalar, vector, or array. An equal-style variable can only use scalar values, which means a global scalar, or an element of a global or per-atom vector or array. Atom-style variables can use the same scalar values. They can also use per-atom vector values. A vector value can be a per-atom vector itself, or a column of an per-atom array. See the doc pages for individual fixes to see what kind of values they produce.

The different kinds of fix references are exactly the same as the compute references listed in the above table, where “c_” is replaced by “f_”. Again, there is typically no ambiguity (see exception below) as to what a reference means, since fixes only produce either global or per-atom quantities, never both.

<table>
<thead>
<tr>
<th>f_ID</th>
<th>global scalar, or per-atom vector</th>
</tr>
</thead>
<tbody>
<tr>
<td>f_ID[I]</td>
<td>Ith element of global vector, or atom I’s value in per-atom vector, or Ith column from per-atom array</td>
</tr>
<tr>
<td>f_ID[I][J]</td>
<td>I,J element of global array, or atom I’s Jth value in per-atom array</td>
</tr>
</tbody>
</table>

Chapter 17. Commands
For I and J indices, integers can be specified or a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for the “Atom Values and Vectors” discussion above.

One source of ambiguity for fix references is the same ambiguity discussed for compute references above. Namely when a vector-style variable refers to a fix that produces both a global scalar and a global vector. The solution is the same as for compute references. For a fix with ID “foo”, “f_foo” will always refer to the global scalar, and “F_foo” can be used to reference the global vector. And similarly for distinguishing between a fix’s global vector versus global array with “f_foo[I]” versus “F_foo[I]”.

Note that if a variable containing a fix is evaluated directly in an input script (not during a run), then the values accessed by the fix should be current. See the discussion below about “Variable Accuracy”.

Note that some fixes only generate quantities on certain timesteps. If a variable attempts to access the fix on non-allowed timesteps, an error is generated. For example, the fix ave/time command may only generate averaged quantities every 100 steps. See the doc pages for individual fix commands for details.

---

### Variable References

Variable references access quantities stored or calculated by other variables, which will cause those variables to be evaluated. The name in the reference should be replaced by the name of a variable defined elsewhere in the input script.

As discussed on this doc page, equal-style variables generate a single global numeric value, vector-style variables generate a vector of global numeric values, and atom-style and atomfile-style variables generate a per-atom vector of numeric values. All other variables store one or more strings.

The formula for an equal-style variable can use any style of variable including a vector_style or atom-style or atomfile-style. For these 3 styles, a subscript must be used to access a single value from the vector-, atom-, or atomfile-style variable. If a string-storing variable is used, the string is converted to a numeric value. Note that this will typically produce a 0.0 if the string is not a numeric string, which is likely not what you want.

The formula for a vector-style variable can use any style of variable, including atom-style or atomfile-style variables. For these 2 styles, a subscript must be used to access a single value from the atom-, or atomfile-style variable.

The formula for an atom-style variable can use any style of variable, including other atom-style or atomfile-style variables. If it uses a vector-style variable, a subscript must be used to access a single value from the vector-style variable.

Examples of different kinds of variable references are as follows. There is no ambiguity as to what a reference means, since variables produce only a global scalar or global vector or per-atom vector.

| v_name | global scalar from equal-style variable |
| v_name | global vector from vector-style variable |
| v_name | per-atom vector from atom-style or atomfile-style variable |
| v_name[I] | Ith element of a global vector from vector-style variable |
| v_name[I] | value of atom with ID = I from atom-style or atomfile-style variable |

For the I index, an integer can be specified or a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for the “Atom Values and Vectors” discussion above.
**17.131.4 Immediate Evaluation of Variables**

If you want an equal-style variable to be evaluated immediately, it may be the case that you do not need to define a variable at all. See the *Commands parse* doc page for info on how to use “immediate” variables in an input script, specified as $(formula) with parenthesis, where the formula has the same syntax as equal-style variables described on this page. This effectively evaluates a formula immediately without using the variable command to define a named variable.

More generally, there is a difference between referencing a variable with a leading $ sign (e.g. $x or ${abc}) versus with a leading “v_” (e.g. v_x or v_abc). The former can be used in any input script command, including a variable command. The input script parser evaluates the reference variable immediately and substitutes its value into the command. As explained on the *Commands parse* doc page, you can also use un-named “immediate” variables for this purpose. For example, a string like this $((xlo+xhi)/2+sqrt(v_area)) in an input script command evaluates the string between the parenthesis as an equal-style variable formula.

Referencing a variable with a leading “v_” is an optional or required kind of argument for some commands (e.g. the fix ave/chunk or dump custom or thermo_style commands) if you wish it to evaluate a variable periodically during a run. It can also be used in a variable formula if you wish to reference a second variable. The second variable will be evaluated whenever the first variable is evaluated.

As an example, suppose you use this command in your input script to define the variable “v” as

```
variable v equal vol
```

before a run where the simulation box size changes. You might think this will assign the initial volume to the variable “v”. That is not the case. Rather it assigns a formula which evaluates the volume (using the thermo_style keyword “vol”) to the variable “v”. If you use the variable “v” in some other command like fix ave/time then the current volume of the box will be evaluated continuously during the run.

If you want to store the initial volume of the system, you can do it this way:

```
variable v equal vol
variable v0 equal $v
```

The second command will force “v” to be evaluated (yielding the initial volume) and assign that value to the variable “v0”. Thus the command

```
thermo_style custom step v_v v_v0
```

would print out both the current and initial volume periodically during the run.

Note that it is a mistake to enclose a variable formula in double quotes if it contains variables preceded by $ signs. For example,

```
variable vratio equal "${vfinal}/${v0}"
```

This is because the quotes prevent variable substitution (explained on the *Commands parse* doc page), and thus an error will occur when the formula for “vratio” is evaluated later.
17.131.5 Variable Accuracy

Obviously, LAMMPS attempts to evaluate variables containing formulas (equal and atom style variables) accurately whenever the evaluation is performed. Depending on what is included in the formula, this may require invoking a compute, either directly or indirectly via a thermo keyword, or accessing a value previously calculated by a compute, or accessing a value calculated and stored by a fix. If the compute is one that calculates the pressure or energy of the system, then these quantities need to be tallied during the evaluation of the interatomic potentials (pair, bond, etc) on timesteps that the variable will need the values.

LAMMPS keeps track of all of this during a run or energy minimization. An error will be generated if you attempt to evaluate a variable on timesteps when it cannot produce accurate values. For example, if a thermo_style custom command prints a variable which accesses values stored by a fix ave/time command and the timesteps on which thermo output is generated are not multiples of the averaging frequency used in the fix command, then an error will occur.

An input script can also request variables be evaluated before or after or in between runs, e.g. by including them in a print command. In this case, if a compute is needed to evaluate a variable (either directly or indirectly), LAMMPS will not invoke the compute, but it will use a value previously calculated by the compute, and can do this only if it was invoked on the current timestep. Fixes will always provide a quantity needed by a variable, but the quantity may or may not be current. This leads to one of three kinds of behavior:

(1) The variable may be evaluated accurately. If it contains references to a compute or fix, and these values were calculated on the last timestep of a preceding run, then they will be accessed and used by the variable and the result will be accurate.

(2) LAMMPS may not be able to evaluate the variable and will generate an error message stating so. For example, if the variable requires a quantity from a compute that has not been invoked on the current timestep, LAMMPS will generate an error. This means, for example, that such a variable cannot be evaluated before the first run has occurred. Likewise, in between runs, a variable containing a compute cannot be evaluated unless the compute was invoked on the last timestep of the preceding run, e.g. by thermodynamic output.

One way to get around this problem is to perform a 0-timestep run before using the variable. For example, these commands

```
variable t equal temp
print "Initial temperature = $t"
run 1000
```

will generate an error if the run is the first run specified in the input script, because generating a value for the “t” variable requires a compute for calculating the temperature to be invoked.

However, this sequence of commands would be fine:

```
run 0
variable t equal temp
print "Initial temperature = $t"
run 1000
```

The 0-timestep run initializes and invokes various computes, including the one for temperature, so that the value it stores is current and can be accessed by the variable “t” after the run has completed. Note that a 0-timestep run does not alter the state of the system, so it does not change the input state for the 1000-timestep run that follows. Also note that the 0-timestep run must actually use and invoke the compute in question (e.g. via thermo or dump output) in order for it to enable the compute to be used in a variable after the run. Thus if you are trying to print a variable that uses a compute you have defined, you can insure it is invoked on the last timestep of the preceding run by including it in thermodynamic output.

Unlike computes, fixes will never generate an error if their values are accessed by a variable in between runs. They always return some value to the variable. However, the value may not be what you expect if the fix has not yet calculated the quantity of interest or it is not current. For example, the fix indent command stores the force on the
indenter. But this is not computed until a run is performed. Thus if a variable attempts to print this value before the first run, zeroes will be output. Again, performing a 0-timestep run before printing the variable has the desired effect.

(3) The variable may be evaluated incorrectly and LAMMPS may have no way to detect this has occurred. Consider the following sequence of commands:

```
pair_coeff 1 1 1.0 1.0
run 1000
pair_coeff 1 1 1.5 1.0
variable e equal pe
print "Final potential energy = $e"
```

The first run is performed using one setting for the pairwise potential defined by the `pair_style` and `pair_coeff` commands. The potential energy is evaluated on the final timestep and stored by the `compute pe` compute (this is done by the `thermo_style` command). Then a pair coefficient is changed, altering the potential energy of the system. When the potential energy is printed via the “e” variable, LAMMPS will use the potential energy value stored by the `compute pe` compute, thinking it is current. There are many other commands which could alter the state of the system between runs, causing a variable to evaluate incorrectly.

The solution to this issue is the same as for case (2) above, namely perform a 0-timestep run before the variable is evaluated to insure the system is up-to-date. For example, this sequence of commands would print a potential energy that reflected the changed pairwise coefficient:

```
pair_coeff 1 1 1.0 1.0
run 1000
pair_coeff 1 1 1.5 1.0
run 0
variable e equal pe
print "Final potential energy = $e"
```

17.131.6 Restrictions

Indexing any formula element by global atom ID, such as an atom value, requires the `atom_style` to use a global mapping in order to look up the vector indices. By default, only atom styles with molecular information create global maps. The `atom_modify map` command can override the default, e.g. for atomic-style atom styles.

All `universe`- and `uloop`-style variables defined in an input script must have the same number of values.

velocity border set NULL 4.0 v_vz sum yes units box
velocity flow scale 300.0
velocity flow ramp vx 0.0 5.0 y 5 25 temp mytemp
velocity all zero linear
17.132.3 Description

Set or change the velocities of a group of atoms in one of several styles. For each style, there are required arguments and optional keyword/value parameters. Not all options are used by each style. Each option has a default as listed below.

The `create` style generates an ensemble of velocities using a random number generator with the specified seed at the specified temperature.

The `set` style sets the velocities of all atoms in the group to the specified values. If any component is specified as NULL, then it is not set. Any of the vx, vy, vz velocity components can be specified as an equal-style or atom-style variable. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated, and its value used to determine the velocity component. Note that if a variable is used, the velocity it calculates must be in box units, not lattice units; see the discussion of the `units` keyword below.

Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters or other parameters.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent velocity field.

The `scale` style computes the current temperature of the group of atoms and then rescales the velocities to the specified temperature.

The `ramp` style is similar to that used by the `compute temp/ramp` command. Velocities ramped uniformly from vlo to vhi are applied to dimension vx, or vy, or vz. The value assigned to a particular atom depends on its relative coordinate value (in dim) from clo to chi. For the example above, an atom with y-coordinate of 10 (1/4 of the way from 5 to 25), would be assigned a x-velocity of 1.25 (1/4 of the way from 0.0 to 5.0). Atoms outside the coordinate bounds (less than 5 or greater than 25 in this case), are assigned velocities equal to vlo or vhi (0.0 or 5.0 in this case).

The `zero` style adjusts the velocities of the group of atoms so that the aggregate linear or angular momentum is zero. No other changes are made to the velocities of the atoms. If the `rigid` option is specified (see below), then the zeroing is performed on individual rigid bodies, as defined by the `fix rigid` or `fix rigid/small` commands. In other words, zero linear will set the linear momentum of each rigid body to zero, and zero angular will set the angular momentum of each rigid body to zero. This is done by adjusting the velocities of the atoms in each rigid body.

All temperatures specified in the velocity command are in temperature units; see the `units` command. The units of velocities and coordinates depend on whether the `units` keyword is set to `box` or `lattice`, as discussed below.

For all styles, no atoms are assigned z-component velocities if the simulation is 2d; see the `dimension` command.

The keyword/value options are used in the following ways by the various styles.

The `dist` keyword is used by `create`. The ensemble of generated velocities can be a uniform distribution from some minimum to maximum value, scaled to produce the requested temperature. Or it can be a gaussian distribution with a mean of 0.0 and a sigma scaled to produce the requested temperature.

The `sum` keyword is used by all styles, except `zero`. The new velocities will be added to the existing ones if sum = yes, or will replace them if sum = no.

The `mom` and `rot` keywords are used by `create`. If mom = yes, the linear momentum of the newly created ensemble of velocities is zeroed; if rot = yes, the angular momentum is zeroed.

If specified, the `temp` keyword is used by `create` and `scale` to specify a `compute` that calculates temperature in a desired way, e.g. by first subtracting out a velocity bias, as discussed on the `Howto thermostat` doc page. If this keyword is not specified, `create` and `scale` calculate temperature using a compute that is defined internally as follows:
**compute velocity_temp group-ID temp**

where group-ID is the same ID used in the velocity command, i.e. the group of atoms whose velocity is being altered. This compute is deleted when the velocity command is finished. See the `compute temp` command for details. If the calculated temperature should have degrees-of-freedom removed due to fix constraints (e.g. SHAKE or rigid-body constraints), then the appropriate fix command must be specified before the velocity command is issued.

The `bias` keyword with a `yes` setting is used by `create` and `scale`, but only if the `temp` keyword is also used to specify a `compute` that calculates temperature in a desired way. If the temperature compute also calculates a velocity bias, the bias is subtracted from atom velocities before the `create` and `scale` operations are performed. After the operations, the bias is added back to the atom velocities. See the `Howto thermostat` doc page for more discussion of temperature computes with biases. Note that the velocity bias is only applied to atoms in the temperature compute specified with the `temp` keyword.

As an example, assume atoms are currently streaming in a flow direction (which could be separately initialized with the `ramp` style), and you wish to initialize their thermal velocity to a desired temperature. In this context thermal velocity means the per-particle velocity that remains when the streaming velocity is subtracted. This can be done using the `create` style with the `temp` keyword specifying the ID of a `compute temp/ramp` or `compute temp/profile` command, and the `bias` keyword set to a `yes` value.

The `loop` keyword is used by `create` in the following ways.

If `loop = all`, then each processor loops over all atoms in the simulation to create velocities, but only stores velocities for atoms it owns. This can be a slow loop for a large simulation. If atoms were read from a data file, the velocity assigned to a particular atom will be the same, independent of how many processors are being used. This will not be the case if atoms were created using the `create_atoms` command, since atom IDs will likely be assigned to atoms differently.

If `loop = local`, then each processor loops over only its atoms to produce velocities. The random number seed is adjusted to give a different set of velocities on each processor. This is a fast loop, but the velocity assigned to a particular atom will depend on which processor owns it. Thus the results will always be different when a simulation is run on a different number of processors.

If `loop = geom`, then each processor loops over only its atoms. For each atom a unique random number seed is created, based on the atom’s xyz coordinates. A velocity is generated using that seed. This is a fast loop and the velocity assigned to a particular atom will be the same, independent of how many processors are used. However, the set of generated velocities may be more correlated than if the `all` or `local` keywords are used.

Note that the `loop geom` keyword will not necessarily assign identical velocities for two simulations run on different machines. This is because the computations based on xyz coordinates are sensitive to tiny differences in the double-precision value for a coordinate as stored on a particular machine.

The `rigid` keyword only has meaning when used with the `zero` style. It allows specification of a fix-ID for one of the rigid-body fix variants which defines a set of rigid bodies. The zeroing of linear or angular momentum is then performed for each rigid body defined by the fix, as described above.

The `units` keyword is used by `set` and `ramp`. If `units = box`, the velocities and coordinates specified in the velocity command are in the standard units described by the `units` command (e.g. Angstroms/fs for real units). If `units = lattice`, velocities are in units of lattice spacings per time (e.g. spacings/fs) and coordinates are in lattice spacings. The `lattice` command must have been previously used to define the lattice spacing.
17.132.4 Restrictions

Assigning a temperature via the `create` style to a system with `rigid bodies` or `SHAKE constraints` may not have the desired outcome for two reasons. First, the velocity command can be invoked before all of the relevant fixes are created and initialized and the number of adjusted degrees of freedom (DOFs) is known. Thus it is not possible to compute the target temperature correctly. Second, the assigned velocities may be partially canceled when constraints are first enforced, leading to a different temperature than desired. A workaround for this is to perform a `run 0` command, which insures all DOFs are accounted for properly, and then rescale the temperature to the desired value before performing a simulation. For example:

```
velocity all create 300.0 12345
run 0  # temperature may not be 300K
velocity all scale 300.0  # now it should be
```

17.132.5 Related commands

`fix rigid, fix shake, lattice`

17.132.6 Default

The keyword defaults are dist = uniform, sum = no, mom = yes, rot = no, bias = no, loop = all, and units = lattice. The temp and rigid keywords are not defined by default.

17.133 write_coeff command

17.133.1 Syntax

```
write_coeff file
```

- file = name of data file to write out

17.133.2 Examples

```
write_coeff polymer.coeff
```

17.133.3 Description

Write a text format file with the currently defined force field coefficients in a way, that it can be read by LAMMPS with the `include` command. In combination with the nocoeff option of `write_data` this can be used to move the Coeffs sections from a data file into a separate file.

**Note:** The `write_coeff` command is not yet fully implemented as some pair styles do not output their coefficient information. This means you will need to add/copy this information manually.
17.133.4 Restrictions

none

17.133.5 Related commands

read_data, write_restart, write_data

17.134 write_data command

17.134.1 Syntax

```
write_data file keyword value ...
```

- `file` = name of data file to write out
- zero or more keyword/value pairs may be appended
- `keyword` = `pair` or `noccoeff`
  - `noccoeff` = do not write out force field info
  - `nofix` = do not write out extra sections read by fixes
  - `pair value` = `ii` or `ij`
    - `ii` = write one line of pair coefficient info per atom type
    - `ij` = write one line of pair coefficient info per IJ atom type pair

17.134.2 Examples

```
write_data data.polymer
write_data data.*
```

17.134.3 Description

Write a data file in text format of the current state of the simulation. Data files can be read by the `read data` command to begin a simulation. The `read_data` command also describes their format.

Similar to `dump` files, the data filename can contain a “*” wild-card character. The “*” is replaced with the current timestep value.

Data in Coeff sections

The `write_data` command may not always write all coefficient settings to the corresponding Coeff sections of the data file. This can have one of multiple reasons. 1) A few styles may be missing the code that would write those sections (if you come across one, please notify the LAMMPS developers). 2) Some pair styles require a single `pair_coeff` statement and those are not compatible with data files. 3) The default for `write_data` is to write a `PairCoeff` section, which has only entries for atom types $i = j$. The remaining coefficients would be inferred through the currently selected mixing rule. If there has been a `pair_coeff` command with $i \neq j$, this setting would be lost. LAMMPS will detect this and print a warning message unless `pair ij` is appended to the `write_data` command. This will request writing a `PairIJCoeff` section which has information for all pairs of atom types. In cases where the coefficient data in the data file is incomplete, you will need to re-specify that information in your input script that reads the data file.
Because a data file is in text format, if you use a data file written out by this command to restart a simulation, the initial state of the new run will be slightly different than the final state of the old run (when the file was written) which was represented internally by LAMMPS in binary format. A new simulation which reads the data file will thus typically diverge from a simulation that continued in the original input script.

If you want to do more exact restarts, using binary files, see the restart, write_restart, and read_restart commands. You can also convert binary restart files to text data files, after a simulation has run, using the -r command-line switch.

Note: Only limited information about a simulation is stored in a data file. For example, no information about atom groups and fixes are stored. Binary restart files store more information.

Bond interactions (angle, etc) that have been turned off by the fix shake or delete_bonds command will be written to a data file as if they are turned on. This means they will need to be turned off again in a new run after the data file is read.

Bonds that are broken (e.g. by a bond-breaking potential) are not written to the data file. Thus these bonds will not exist when the data file is read.

The nocoeff keyword requests that no force field parameters should be written to the data file. This can be very helpful, if one wants to make significant changes to the force field or if the parameters are read in separately anyway, e.g. from an include file.

The nofix keyword requests that no extra sections read by fixes should be written to the data file (see the fix option of the read_data command for details). For example, this option excludes sections for user-created per-atom properties from fix property/atom.

The pair keyword lets you specify in what format the pair coefficient information is written into the data file. If the value is specified as ii, then one line per atom type is written, to specify the coefficients for each of the I=J interactions. This means that no cross-interactions for I != J will be specified in the data file and the pair style will apply its mixing rule, as documented on individual pair_style doc pages. Of course this behavior can be overridden in the input script after reading the data file, by specifying additional pair_coeff commands for any desired I,J pairs.

If the value is specified as ij, then one line of coefficients is written for all I,J pairs where I <= J. These coefficients will include any specific settings made in the input script up to that point. The presence of these I != J coefficients in the data file will effectively turn off the default mixing rule for the pair style. Again, the coefficient values in the data file can be overridden in the input script after reading the data file, by specifying additional pair_coeff commands for any desired I,J pairs.

17.134.4 Restrictions

This command requires inter-processor communication to migrate atoms before the data file is written. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses initialized, etc).
17.134.5 Related commands

17.135 write_dump command

17.135.1 Syntax

```
write_dump group-ID style file dump-args modify dump_modify-args
```

- group-ID = ID of the group of atoms to be dumped
- style = any of the supported dump styles
- file = name of file to write dump info to
- dump-args = any additional args needed for a particular dump style
- modify = all args after this keyword are passed to dump_modify (optional)
- dump-modify-args = args for dump_modify (optional)

17.135.2 Examples

```
write_dump all atom dump.atom
write_dump subgroup atom dump.run.bin
write_dump all custom dump.myforce.* id type x y vx fx
write_dump flow custom dump.%myforce id type c_myF[3] v_ke modify sort id
write_dump all xyz system.xyz modify sort id element O H
write_dump all image snap*.jpg type type size 960 960 modify backcolor white
write_dump all image snap*.jpg element element &
    bond atom 0.3 shiny 0.1 ssao yes 6345 0.2 size 1600 1600 &

write_dump flow custom/zstd dump.%myforce.zst &
    id type c_myF[3] v_ke &
    modify sort id &
    compression_level 15
```
17.135.3 Description

Dump a single snapshot of atom quantities to one or more files for the current state of the system. This is a one-time immediate operation, in contrast to the dump command which will set up a dump style to write out snapshots periodically during a running simulation.

The syntax for this command is mostly identical to that of the dump and dump_modify commands as if they were concatenated together, with the following exceptions: There is no need for a dump ID or dump frequency and the keyword modify is added. The latter is so that the full range of dump_modify options can be specified for the single snapshot, just as they can be for multiple snapshots. The modify keyword separates the arguments that would normally be passed to the dump command from those that would be given the dump_modify. Both support optional arguments and thus LAMMPS needs to be able to cleanly separate the two sets of args.

Note that if the specified filename uses wildcard characters “*” or “%”, as supported by the dump command, they will operate in the same fashion to create the new filename(s). Normally, dump image files require a filename with a “*” character for the timestep. That is not the case for the write_dump command; no wildcard “*” character is necessary.

17.135.4 Restrictions

All restrictions for the dump and dump_modify commands apply to this command as well, with the exception of the dump image filename not requiring a wildcard “*” character, as noted above.

Since dumps are normally written during a run or energy minimization, the simulation has to be ready to run before this command can be used. Similarly, if the dump requires information from a compute, fix, or variable, the information needs to have been calculated for the current timestep (e.g. by a prior run), else LAMMPS will generate an error message.

For example, it is not possible to dump per-atom energy with this command before a run has been performed, since no energies and forces have yet been calculated. See the variable doc page section on Variable Accuracy for more information on this topic.

17.135.5 Related commands

dump, dump image, dump_modify

17.135.6 Default

The defaults are listed on the doc pages for the dump and dump image and dump_modify commands.

17.136 write_restart command

17.136.1 Syntax

write_restart file keyword value ...

- file = name of file to write restart information to
- zero or more keyword/value pairs may be appended
- keyword = fileper or nfile
17.136.2 Examples

```bash
write_restart restart.equil
write_restart restart.equil.mpiio
write_restart poly.%.* nfile 10
```

17.136.3 Description

Write a binary restart file of the current state of the simulation.

During a long simulation, the `restart` command is typically used to output restart files periodically. The `write_restart` command is useful after a minimization or whenever you wish to write out a single current restart file.

Similar to `dump` files, the restart filename can contain two wild-card characters. If a “*” appears in the filename, it is replaced with the current timestep value. If a “%” character appears in the filename, then one file is written by each processor and the “%” character is replaced with the processor ID from 0 to P-1. An additional file with the “%” replaced by “base” is also written, which contains global information. For example, the files written for filename `restart.%` would be `restart.base`, `restart.0`, `restart.1`, … `restart.P-1`. This creates smaller files and can be a fast mode of output and subsequent input on parallel machines that support parallel I/O. The optional `fileper` and `nfile` keywords discussed below can alter the number of files written.

The restart file can also be written in parallel as one large binary file via the MPI-IO library, which is part of the MPI standard for versions 2.0 and above. Using MPI-IO requires two steps. First, build LAMMPS with its MPIIO package installed, e.g.

```bash
make yes-mpiio # installs the MPIIO package
make mpi       # build LAMMPS for your platform
```

Second, use a restart filename which contains “.mpiio”. Note that it does not have to end in “.mpiio”, just contain those characters. Unlike MPI-IO dump files, a particular restart file must be both written and read using MPI-IO.

Restart files can be read by a `read_restart` command to restart a simulation from a particular state. Because the file is binary (to enable exact restarts), it may not be readable on another machine. In this case, you can use the `-r` command-line switch to convert a restart file to a data file.

Note: Although the purpose of restart files is to enable restarting a simulation from where it left off, not all information about a simulation is stored in the file. For example, the list of fixes that were specified during the initial run is not stored, which means the new input script must specify any fixes you want to use. Even when restart information is stored in the file, as it is for some fixes, commands may need to be re-specified in the new input script, in order to re-use that information. Details are usually given in the documentation of the respective command. Also, see the `read_restart` command for general information about what is stored in a restart file.

The optional `nfile` or `fileper` keywords can be used in conjunction with the “%” wildcard character in the specified restart file name. As explained above, the “%” character causes the restart file to be written in pieces, one piece for each of P processors. By default P = the number of processors the simulation is running on. The `nfile` or `fileper` keyword can be used to set P to a smaller value, which can be more efficient when running on a large number of processors.
The *nfile* keyword sets P to the specified Nf value. For example, if Nf = 4, and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a restart file.

For the *fileper* keyword, the specified value of Np means write one file for every Np processors. For example, if Np = 4, every fourth processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a restart file.

### 17.136.4 Restrictions

This command requires inter-processor communication to migrate atoms before the restart file is written. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses initialized, etc).

To write and read restart files in parallel with MPI-IO, the MPIIO package must be installed.

### 17.136.5 Related commands

`restart, read_restart, write_data`

### 17.136.6 Default

`none`
18.1 fix accelerate/cos command

18.1.1 Syntax

```
fix ID group-ID accelerate value
```

- ID, group-ID are documented in fix command
- accelerate/cos = style name of this fix command
- value = amplitude of acceleration (in unit of force/mass)

18.1.2 Examples

```
fix 1 all accelerate/cos 0.02e-5
```

18.1.3 Description

Give each atom a acceleration in x-direction based on its z coordinate. The acceleration is a periodic function along the z-direction:

\[
a_x(z) = A \cos \left( \frac{2\pi z}{l_z} \right)
\]

where \( A \) is the acceleration amplitude, \( l_z \) is the z-length of the simulation box. At steady state, the acceleration generates a velocity profile:

\[
v_x(z) = V \cos \left( \frac{2\pi z}{l_z} \right)
\]

The generated velocity amplitude \( V \) is related to the shear viscosity \( \eta \) by:

\[
V = \frac{A \rho}{\eta} \left( \frac{l_z}{2\pi} \right)^2
\]

and it can be obtained from ensemble average of the velocity profile:

\[
V = \frac{\sum_i 2m_i v_{i,x} \cos \left( \frac{2\pi z_i}{l_z} \right)}{\sum_i m_i}
\]
where \( m_i, v_{i,x} \) and \( z_i \) are the mass, x-component velocity and z coordinate of a particle.

The velocity amplitude \( V \) can be calculated with `compute viscosity/cos`, which enables viscosity calculation with periodic perturbation method, as described by Hess. Because the applied acceleration drives the system away from equilibration, the calculated shear viscosity is lower than the intrinsic viscosity due to the shear-thinning effect. Extrapolation to zero acceleration should generally be performed to predict the zero-shear viscosity. As the shear stress decreases, the signal-noise ratio decreases rapidly, the simulation time must be extended accordingly to get converged result.

In order to get meaningful result, the group ID of this fix should be all.

### 18.1.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

### 18.1.5 Restrictions

This command is only available when LAMMPS was built with the USER-MISC package. Since this fix depends on the \( z \)-coordinate of atoms, it cannot be used in 2d simulations.

### 18.1.6 Related commands

`compute viscosity/cos`

### 18.1.7 Default

```
none
```

### 18.2 fix adapt command

#### 18.2.1 Syntax

```
fix ID group-ID adapt N attribute args ... keyword value ...
```

- ID, group-ID are documented in `fix` command
- adapt = style name of this fix command
- N = adapt simulation settings every this many timesteps
- one or more attribute/arg pairs may be appended
- attribute = `pair` or `bond` or `kspace` or `atom`
pair args = pstyle pparam I J v_name
   pstyle = pair style name, e.g. lj/cut
   pparam = parameter to adapt over time
   I,J = type pair(s) to set parameter for
   v_name = variable with name that calculates value of pparam

bond args = bstyle bparam I v_name
   bstyle = bond style name, e.g. harmonic
   bparam = parameter to adapt over time
   I = type bond to set parameter for
   v_name = variable with name that calculates value of bparam

kspace arg = v_name
   v_name = variable with name that calculates scale factor on K-space

atom args = aparam v_name
   aparam = parameter to adapt over time
   v_name = variable with name that calculates value of aparam

- zero or more keyword/value pairs may be appended
- keyword = scale or reset or mass
  scale value = no or yes
    no = the variable value is the new setting
    yes = the variable value multiplies the original setting
  reset value = no or yes
    no = values will remain altered at the end of a run
    yes = reset altered values to their original values at the end of a run
  mass value = no or yes
    no = mass is not altered by changes in diameter
    yes = mass is altered by changes in diameter

18.2.2 Examples

```
fix 1 all adapt 1 pair soft a 1 1 v_prefactor
fix 1 all adapt 1 pair soft a 2* 3 v_prefactor
fix 1 all adapt 1 pair lj/cut epsilon * * v_scale1 pair coul/cut scale 3 3 v_scale2
   scale yes reset yes
fix 1 all adapt 10 atom diameter v_size
variable ramp_up equal "ramp(0.01,0.5)"
fix stretch all adapt 1 bond harmonic r0 1 v_ramp_up
```

18.2.3 Description

Change or adapt one or more specific simulation attributes or settings over time as a simulation runs. Pair potential
and K-space and atom attributes which can be varied by this fix are discussed below. Many other fixes can also be
used to time-vary simulation parameters, e.g. the “fix deform” command will change the simulation box size/shape
and the “fix move” command will change atom positions and velocities in a prescribed manner. Also note that many
commands allow variables as arguments for specific parameters, if described in that manner on their doc pages. An
equal-style variable can calculate a time-dependent quantity, so this is another way to vary a simulation parameter over
time.

If \( N \) is specified as 0, the specified attributes are only changed once, before the simulation begins. This is all that is
needed if the associated variables are not time-dependent. If \( N > 0 \), then changes are made every \( N \) steps during the
Depending on the value of the *reset* keyword, attributes changed by this fix will or will not be reset back to their original values at the end of a simulation. Even if *reset* is specified as *yes*, a restart file written during a simulation will contain the modified settings.

If the *scale* keyword is set to *no*, which is the default, then the value of the altered parameter will be whatever the variable generates. If the *scale* keyword is set to *yes*, then the value of the altered parameter will be the initial value of that parameter multiplied by whatever the variable generates. I.e. the variable is now a “scale factor” applied in (presumably) a time-varying fashion to the parameter.

Note that whether scale is *no* or *yes*, internally, the parameters themselves are actually altered by this fix. Make sure you use the *reset yes* option if you want the parameters to be restored to their initial values after the run.

The *pair* keyword enables various parameters of potentials defined by the *pair_style* command to be changed, if the pair style supports it. Note that the *pair_style* and *pair_coeff* commands must be used in the usual manner to specify these parameters initially; the fix adapt command simply overrides the parameters.

The *pstyle* argument is the name of the pair style. If *pair_style hybrid or hybrid/overlay* is used, *pstyle* should be a sub-style name. If there are multiple sub-styles using the same pair style, then *pstyle* should be specified as “style:N” where N is which instance of the pair style you wish to adapt, e.g. the first, second, etc. For example, *pstyle* could be specified as “soft” or “lubricate” or “lj/cut:1” or “lj/cut:2”. The *pparam* argument is the name of the parameter to change. This is the current list of pair styles and parameters that can be varied by this fix. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

**Note:** It is easy to add new pairwise potentials and their parameters to this list. All it typically takes is adding an `extract()` method to the `pair_*`.cpp file associated with the potential.

Some parameters are global settings for the pair style, e.g. the viscosity setting “mu” for `pair_style lubricate`. Other parameters apply to atom type pairs within the pair style, e.g. the prefactor “a” for `pair_style soft`.

Note that for many of the potentials, the parameter that can be varied is effectively a prefactor on the entire energy expression for the potential, e.g. the lj/cut epsilon. The parameters listed as “scale” are exactly that, since the energy expression for the `coul/cut` potential (for example) has no labeled prefactor in its formula. To apply an effective prefactor to some potentials, multiple parameters need to be altered. For example, the Buckingham potential needs both the A and C terms altered together. To scale the Buckingham potential, you should thus list the pair style twice, once for A and once for C.

If a type pair parameter is specified, the `I` and `J` settings should be specified to indicate which type pairs to apply it to. If a global parameter is specified, the `I` and `J` settings still need to be specified, but are ignored.

Similar to the `pair_coeff` command, `I` and `J` can be specified in one of two ways. Explicit numeric values can be used for each, as in the first example above. `I <= J` is required. LAMMPS sets the coefficients for the symmetric J,I interaction to the same values.

A wild-card asterisk can be used in place of or in conjunction with the `I` and `J` arguments to set the coefficients for multiple type pairs of atom types. This takes the form “*n” or “n*” or “n*n” or “m*n”. If `N` is the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that only type pairs with `I <= J` are considered; if asterisks imply type pairs where `J < I`, they are ignored.

**IMPORTANT NOTE:** If `pair_style hybrid` or `hybrid/overlay` is being used, then the `pstyle` will be a sub-style name. You must specify `I` and `J` arguments that correspond to type pair values defined (via the `pair_coeff` command) for that sub-style.

The `v_name` argument for keyword `pair` is the name of an `equal-style variable` which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as `v_name`, where name is the variable name. Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify parameters that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the `start` and `stop` keywords of the `run` command and the `elaplong` keyword of `thermo_style custom` for details.

For example, these commands would change the prefactor coefficient of the `pair_style soft` potential from 10.0 to 30.0 in a linear fashion over the course of a simulation:

```plaintext
variable prefactor equal ramp(10,30)
fix 1 all adapt 1 pair soft a * v_prefactor
```
The *bond* keyword uses the specified variable to change the value of a bond coefficient over time, very similar to how the *pair* keyword operates. The only difference is that now a bond coefficient for a given bond type is adapted.

A wild-card asterisk can be used in place of or in conjunction with the bond type argument to set the coefficients for multiple bond types. This takes the form “*” or “*n” or “n*” or “m*n”. If \( N \) = the number of atom types, then an asterisk with no numeric values means all types from 1 to \( N \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( N \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive).

Currently *bond* does not support bond_style hybrid nor bond_style hybrid/overlay as bond styles. The only bonds that currently are working with fix_adapt are

The *kspace* keyword used the specified variable as a scale factor on the energy, forces, virial calculated by whatever K-Space solver is defined by the *kspace_style* command. If the variable has a value of 1.0, then the solver is unaltered.

The *kspace* keyword works this way whether the *scale* keyword is set to *no* or *yes*.

The *atom* keyword enables various atom properties to be changed. The *aparam* argument is the name of the parameter to change. This is the current list of atom parameters that can be varied by this fix:

- charge = charge on particle
- diameter or diameter/disc = diameter of particle

The *v_name* argument of the *atom* keyword is the name of an equal-style variable which will be evaluated each time this fix is invoked to set, or scale the parameter to a new value. It should be specified as *v_name*, where name is the variable name. See the discussion above describing the formulas associated with equal-style variables. The new value is assigned to the corresponding attribute for all atoms in the fix group.

If the atom parameter is *diameter* and per-atom density and per-atom mass are defined for particles (e.g. *atom_style granular*), then the mass of each particle is, by default, also changed when the diameter changes. The mass is set from the particle volume for 3d systems (density is assumed to stay constant). For 2d, the default is for LAMMPS to model particles with a radius attribute as spheres. However, if the atom parameter is *diameter/disc*, then the mass is set from the particle area (the density is assumed to be in mass/distance^2 units). The mass of the particle may also be kept constant if the *mass* keyword is set to *no*. This can be useful to account for diameter changes that do not involve mass changes, e.g., thermal expansion.

For example, these commands would shrink the diameter of all granular particles in the “center” group from 1.0 to 0.1 in a linear fashion over the course of a 1000-step simulation:

```
variable size equal ramp(1.0,0.1)
fix 1 center adapt 10 atom diameter v_size
```

This fix can be used in long simulations which are restarted one or more times to continuously adapt simulation parameters, but it must be done carefully. There are two issues to consider. The first is how to adapt the parameters
in a continuous manner from one simulation to the next. The second is how, if desired, to reset the parameters to their original values at the end of the last restarted run.

Note that all the parameters changed by this fix are written into a restart file in their current changed state. A new restarted simulation does not know their original time=0 values, unless the input script explicitly resets the parameters (after the restart file is read), to their original values.

Also note, that the time-dependent variable(s) used in the restart script should typically be written as a function of time elapsed since the original simulation began.

With this in mind, if the scale keyword is set to no (the default) in a restarted simulation, original parameters are not needed. The adapted parameters should seamlessly continue their variation relative to the preceding simulation.

If the scale keyword is set to yes, then the input script should typically reset the parameters being adapted to their original values, so that the scaling formula specified by the variable will operate correctly. An exception is if the atom keyword is being used with scale yes. In this case, information is added to the restart file so that per-atom properties in the new run will automatically be scaled relative to their original values. This will only work if the fix adapt command specified in the restart script has the same ID as the one used in the original script.

In a restarted run, if the reset keyword is set to yes, and the run ends in this script (as opposed to just writing more restart files, parameters will be restored to the values they were at the beginning of the run command in the restart script. Which as explained above, may or may not be the original values of the parameters. Again, an exception is if the atom keyword is being used with reset yes (in all the runs). In that case, the original per-atom parameters are stored in the restart file, and will be restored when the restarted run finally completes.

18.2.4 Restart, fix_modify, output, run start/stop, minimize info

If the atom keyword is used and the scale or reset keyword is set to yes, then this fix writes information to a restart file so that in a restarted run scaling can continue in a seamless manner and/or the per-atom values can be restored, as explained above.

None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

For rRESPA time integration, this fix changes parameters on the outermost rRESPA level.

18.3.1 Syntax

```plaintext
fix ID group-ID adapt/fep N attribute args ... keyword value ...
```

- ID, group-ID are documented in `fix` command
- adapt/fep = style name of this fix command
- N = adapt simulation settings every this many timesteps
- one or more attribute/arg pairs may be appended
- attribute = `pair` or `kspace` or `atom`
  
  `pair args = pstyle pparam I J v_name`
  `pstyle = pair style name, e.g. lj/cut`
  `pparam = parameter to adapt over time`
  `I,J = type pair(s) to set parameter for`
  `v_name = variable with name that calculates value of pparam`

- `kspace arg = v_name`
  `v_name = variable with name that calculates scale factor on K-space`

- `atom args = aparam v_name`
  `aparam = parameter to adapt over time`
  `I = type(s) to set parameter for`
  `v_name = variable with name that calculates value of aparam`

- zero or more keyword/value pairs may be appended
- keyword = `scale` or `reset` or `after`
  
  `scale value = no or yes`
  `no = the variable value is the new setting`
  `yes = the variable value multiplies the original setting`

  `reset value = no or yes`
  `no = values will remain altered at the end of a run`
  `yes = reset altered values to their original values at the end of a run`

  `after value = no or yes`
  `no = parameters are adapted at timestep N`
  `yes = parameters are adapted one timestep after N`
18.3.2 Examples

```
fix 1 all adapt/fep 1 pair soft a 1.1 v_prefactor
fix 1 all adapt/fep 1 pair soft a 2*3 v_prefactor
fix 1 all adapt/fep 1 pair lj/cut epsilon * * v_scale1 coul/cut scale 3 3 v_scale2
   scale yes reset yes
fix 1 all adapt/fep 10 atom diameter 1 v_size
```

18.3.3 Description

Change or adapt one or more specific simulation attributes or settings over time as a simulation runs.

This is an enhanced version of the `fix adapt` command with two differences,

- It is possible to modify the charges of chosen atom types only, instead of scaling all the charges in the system.
- There is a new option `after` for better compatibility with “fix ave/time”.

This version is suited for free energy calculations using `compute ti` or `compute fep`.

If $N$ is specified as 0, the specified attributes are only changed once, before the simulation begins. This is all that is needed if the associated variables are not time-dependent. If $N > 0$, then changes are made every $N$ steps during the simulation, presumably with a variable that is time-dependent.

Depending on the value of the `reset` keyword, attributes changed by this fix will or will not be reset back to their original values at the end of a simulation. Even if `reset` is specified as `yes`, a restart file written during a simulation will contain the modified settings.

If the `scale` keyword is set to `no`, then the value the parameter is set to will be whatever the variable generates. If the `scale` keyword is set to `yes`, then the value of the altered parameter will be the initial value of that parameter multiplied by whatever the variable generates. I.e. the variable is now a “scale factor” applied in (presumably) a time-varying fashion to the parameter. Internally, the parameters themselves are actually altered; make sure you use the `reset yes` option if you want the parameters to be restored to their initial values after the run.

If the `after` keyword is set to `yes`, then the parameters are changed one timestep after the multiple of N. In this manner, if a fix such as “fix ave/time” is used to calculate averages at every N timesteps, all the contributions to the average will be obtained with the same values of the parameters.

The `pair` keyword enables various parameters of potentials defined by the `pair_style` command to be changed, if the pair style supports it. Note that the `pair_style` and `pair_coeff` commands must be used in the usual manner to specify these parameters initially; the fix adapt command simply overrides the parameters.

The `pstyle` argument is the name of the pair style. If `pair_style hybrid or hybrid/overlay` is used, `pstyle` should be a sub-style name. For example, `pstyle` could be specified as “soft” or “lubricate”. The `pparam` argument is the name of the parameter to change. This is the current list of pair styles and parameters that can be varied by this fix. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:
Note: It is easy to add new potentials and their parameters to this list. All it typically takes is adding an extract() method to the pair_*.cpp file associated with the potential.

Note that for many of the potentials, the parameter that can be varied is effectively a prefactor on the entire energy expression for the potential, e.g. the lj/cut epsilon. The parameters listed as “scale” are exactly that, since the energy expression for the coul/cut potential (for example) has no labeled prefactor in its formula. To apply an effective prefactor to some potentials, multiple parameters need to be altered. For example, the Buckingham potential needs both the A and C terms altered together. To scale the Buckingham potential, you should thus list the pair style twice, once for A and once for C.

If a type pair parameter is specified, the I and J settings should be specified to indicate which type pairs to apply it to. If a global parameter is specified, the I and J settings still need to be specified, but are ignored.

Similar to the pair_coeff command, I and J can be specified in one of two ways. Explicit numeric values can be used for each, as in the first example above. I <= J is required. LAMMPS sets the coefficients for the symmetric J,I interaction to the same values.

A wild-card asterisk can be used in place of or in conjunction with the LJ arguments to set the coefficients for multiple pairs of atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that only type pairs with I <= J are considered; if asterisks imply type pairs where J < I, they are ignored.

IMPORTANT NOTE: If pair_style hybrid or hybrid/overlay is being used, then the pstyle will be a sub-style name.
You must specify I,J arguments that correspond to type pair values defined (via the `pair_coeff` command) for that sub-style.

The `v_name` argument for keyword `pair` is the name of an `equal-style variable` which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as `v_name`, where `name` is the variable name. Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify parameters that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the `start` and `stop` keywords of the `run` command and the `elaplong` keyword of `thermo_style custom` for details.

For example, these commands would change the prefactor coefficient of the `pair_style soft` potential from 10.0 to 30.0 in a linear fashion over the course of a simulation:

```plaintext
variable prefactor equal ramp(10,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

The `kspace` keyword uses the specified variable as a scale factor on the energy, forces, virial calculated by whatever K-Space solver is defined by the `kspace_style` command. If the variable has a value of 1.0, then the solver is unaltered.

The `kspace` keyword works this way whether the `scale` keyword is set to `no` or `yes`.

The `atom` keyword enables various atom properties to be changed. The `aparam` argument is the name of the parameter to change. This is the current list of atom parameters that can be varied by this fix:

- charge = charge on particle
- diameter = diameter of particle

The `I` argument indicates which atom types are affected. A wild-card asterisk can be used in place of or in conjunction with the `I` argument to set the coefficients for multiple atom types.

The `v_name` argument of the `atom` keyword is the name of an `equal-style variable` which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as `v_name`, where `name` is the variable name. See the discussion above describing the formulas associated with equal-style variables. The new value is assigned to the corresponding attribute for all atoms in the fix group.

If the atom parameter is `diameter` and per-atom density and per-atom mass are defined for particles (e.g. `atom_style granular`), then the mass of each particle is also changed when the diameter changes (density is assumed to stay constant).

For example, these commands would shrink the diameter of all granular particles in the “center” group from 1.0 to 0.1 in a linear fashion over the course of a 1000-step simulation:

```plaintext
variable size equal ramp(1.0,0.1)
fix 1 center adapt 10 atom diameter * v_size
```

For `rRESPA time integration`, this fix changes parameters on the outermost rRESPA level.
18.3.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.3.5 Restrictions

none

18.3.6 Related commands

compute fep, fix adapt, compute ti, pair_style */soft

18.3.7 Default

The option defaults are scale = no, reset = no, after = no.

18.4 fix addforce command

18.4.1 Syntax

```latex
fix ID group-ID addforce fx fy fz keyword value ...
```

- ID, group-ID are documented in fix command
- addforce = style name of this fix command
- fx,fy,fz = force component values (force units)

any of fx,fy,fz can be a variable (see below)

- zero or more keyword/value pairs may be appended to args
- keyword = every or region or energy

```latex
every value = Nevery
   Nevery = add force every this many timesteps
region value = region-ID
   region-ID = ID of region atoms must be in to have added force
energy value = v_name
   v_name = variable with name that calculates the potential energy of
         each atom in the added force field
```
18.4.2 Examples

```
fix kick flow addforce 1.0 0.0 0.0
fix kick flow addforce 1.0 0.0 v_oscillate
fix ff boundary addforce 0.0 0.0 v_push energy v_espace
```

18.4.3 Description

Add \( fx, fy, fz \) to the corresponding component of force for each atom in the group. This command can be used to give an additional push to atoms in a simulation, such as for a simulation of Poiseuille flow in a channel.

Any of the 3 quantities defining the force components can be specified as an equal-style or atom-style variable, namely \( fx, fy, fz \). If the value is a variable, it should be specified as \( v\_name \), where \( name \) is the variable name. In this case, the variable will be evaluated each timestep, and its value(s) used to determine the force component.

Equal-style variables can specify formulas with various mathematical functions, and include the `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent force field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent force field with optional time-dependence as well.

If the `every` keyword is used, the `Nevery` setting determines how often the forces are applied. The default value is 1, for every timestep.

If the `region` keyword is used, the atom must also be in the specified geometric `region` in order to have force added to it.

Adding a force to atoms implies a change in their potential energy as they move due to the applied force field. For dynamics via the “run” command, this energy can be optionally added to the system’s potential energy for thermodynamic output (see below). For energy minimization via the “minimize” command, this energy must be added to the system’s potential energy to formulate a self-consistent minimization problem (see below).

The `energy` keyword is not allowed if the added force is a constant vector \( F = (fx,fy,fz) \), with all components defined as numeric constants and not as variables. This is because LAMMPS can compute the energy for each atom directly as \( E = -x \cdot F = -x^*fx + y^*fy + z^*fz \), so that \(-\text{Grad}(E) = F\).

The `energy` keyword is optional if the added force is defined with one or more variables, and if you are performing dynamics via the `run` command. If the keyword is not used, LAMMPS will set the energy to 0.0, which is typically fine for dynamics.

The `energy` keyword is required if the added force is defined with one or more variables, and you are performing energy minimization via the “minimize” command. The keyword specifies the name of an atom-style variable which is used to compute the energy of each atom as function of its position. Like variables used for \( fx, fy, fz \), the energy variable is specified as \( v\_name \), where \( name \) is the variable name.

Note that when the `energy` keyword is used during an energy minimization, you must insure that the formula defined for the atom-style variable is consistent with the force variable formulas, i.e. that \(-\text{Grad}(E) = F\). For example, if the force were a spring-like \( F = kx \), then the energy formula should be \( E = -0.5kx^2 \). If you don’t do this correctly, the minimization will not converge properly.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 18.4.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the potential “energy” inferred by the added force to the system’s potential energy as part of thermodynamic output. This is a fictitious quantity but is needed so that the minimize command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added force.

The fix_modify virial option is supported by this fix to add the contribution due to the added forces on atoms to the system’s virial as part of thermodynamic output. The default is virial no

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar and a global 3-vector of forces, which can be accessed by various output commands. The scalar is the potential energy discussed above. The vector is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

### 18.4.5 Restrictions

none

### 18.4.6 Related commands

fix setforce, fix aveforce
18.4.7 Default

The option default for the every keyword is every = 1.

18.5 fix addtorque command

18.5.1 Syntax

fix ID group-ID addtorque Tx Ty Tz

- ID, group-ID are documented in fix command
- addtorque = style name of this fix command
- Tx,Ty,Tz = torque component values (torque units)
- any of Tx,Ty,Tz can be a variable (see below)

18.5.2 Examples

```
fix kick bead addtorque 2.0 3.0 5.0
fix kick bead addtorque 0.0 0.0 v_oscillate
```

18.5.3 Description

Add a set of forces to each atom in the group such that:
- the components of the total torque applied on the group (around its center of mass) are Tx,Ty,Tz
- the group would move as a rigid body in the absence of other forces.

This command can be used to drive a group of atoms into rotation.

Any of the 3 quantities defining the torque components can be specified as an equal-style variable, namely Tx, Ty, Tz. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the torque component.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent torque.

18.5.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the potential “energy” inferred by the added forces to the system’s potential energy as part of thermodynamic output. This is a fictitious quantity but is needed so that the minimize command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added forces.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its torque. Default is the outermost level.
This fix computes a global scalar and a global 3-vector, which can be accessed by various output commands. The scalar is the potential energy discussed above. The vector is the total torque on the group of atoms before the forces on individual atoms are changed by the fix. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

18.5.5 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.5.6 Related commands

fix addforce

18.5.7 Default

none

18.6 fix append/atoms command

18.6.1 Syntax

```
fix ID group-ID append/atoms face ... keyword value ...
```

- ID, group-ID are documented in fix command
- append/atoms = style name of this fix command
- face = zhi
- zero or more keyword/value pairs may be appended
- keyword = basis or size or freq or temp or random or units

- `basis values = M itype`
  - `M = which basis atom`
  - `itype = atom type (1-N) to assign to this basis atom`
- `size args = Lz`
  - `Lz = z size of lattice region appended in a single event (distance units)`
- `freq args = freq`
  - `freq = the number of timesteps between append events`
- `temp args = target damp seed extent`
  - `target = target temperature for the region between zhi-extent and zhi`
  - `damp = damping parameter (time units)`
  - `seed = random number seed for langevin kicks`
  - `extent = extent of thermostatted region (distance units)`
- `random args = xmax ymax zmax seed`
xmax, ymax, zmax = maximum displacement in particular direction (distance units)
seed = random number seed for random displacement
units value = lattice or box
lattice = the wall position is defined in lattice units
box = the wall position is defined in simulation box units

18.6.2 Examples

```
fix 1 all append/atoms zhi size 5.0 freq 295 units lattice
fix 4 all append/atoms zhi size 15.0 freq 5 units box
fix A all append/atoms zhi size 1.0 freq 1000 units lattice
```

18.6.3 Description

This fix creates atoms on a lattice, appended on the zhi edge of the system box. This can be useful when a shock or wave is propagating from zlo. This allows the system to grow with time to accommodate an expanding wave. A simulation box must already exist, which is typically created via the `create_box` command. Before using this command, a lattice must also be defined using the `lattice` command.

This fix will automatically freeze atoms on the zhi edge of the system, so that overlaps are avoided when new atoms are appended.

The `basis` keyword specifies an atom type that will be assigned to specific basis atoms as they are created. See the `lattice` command for specifics on how basis atoms are defined for the unit cell of the lattice. By default, all created atoms are assigned type = 1 unless this keyword specifies differently.

The `size` keyword defines the size in z of the chunk of material to be added.

The `random` keyword will give the atoms random displacements around their lattice points to simulate some initial temperature.

The `temp` keyword will cause a region to be thermostatted with a Langevin thermostat on the zhi boundary. The size of the region is measured from zhi and is set with the `extent` argument.

The `units` keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used. A `box` value selects standard distance units as defined by the `units` command, e.g. Angstroms for units = real or metal. A `lattice` value means the distance units are in lattice spacings. The `lattice` command must have been previously used to define the lattice spacings.

18.6.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.
18.6.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The boundary on which atoms are added with append/atoms must be shrink/minimum. The opposite boundary may be any boundary type other than periodic.

18.6.6 Related commands

fix wall/piston command

18.6.7 Default

The keyword defaults are size = 0.0, freq = 0, units = lattice. All added atoms are of type 1 unless the basis keyword is used.

18.7 fix atc command

18.7.1 Syntax

```plaintext
fix <fixID> <group> atc <type> <parameter_file>
```

- fixID = name of fix
- group = name of group fix is to be applied
- type = thermal or two_temperature or hardy or field
  - thermal = thermal coupling with fields: temperature
  - two_temperature = electron-phonon coupling with field: temperature and electron_temperature
  - hardy = on-the-fly post-processing using kernel localization functions
  - field = on-the-fly post-processing using mesh-based localization functions
- parameter_file = name of the file with material parameters. Note: Neither hardy nor field requires a parameter file

18.7.2 Examples

```plaintext
fix AtC internal atc thermal Ar_thermal.dat
fix AtC internal atc two_temperature Ar_ttm.mat
fix AtC internal atc hardy
fix AtC internal atc field
```
18.7.3 Description

This fix is the beginning to creating a coupled FE/MD simulation and/or an on-the-fly estimation of continuum fields. The coupled versions of this fix do not do Verlet integration and the post-processing does not. After instantiating this fix, several other fix_modify commands will be needed to set up the problem, e.g. define the finite element mesh and prescribe initial and boundary conditions.

The following coupling example is typical, but non-exhaustive:

```plaintext
# ... commands to create and initialize the MD system

# initial fix to designate coupling type and group to apply it to
# tag group physics material_file
fix AtC internal atc thermal Ar_thermal.mat

# create a uniform 12 x 2 x 2 mesh that covers region contain the group
# nx ny nz region periodicity
fix_modify AtC mesh create 12 2 2 mdRegion f p p

# specify the control method for the type of coupling
# physics control_type
fix_modify AtC thermal control flux

# specify the initial values for the empirical field "temperature"
# field node_group value
fix_modify AtC initial temperature all 30

# create an output stream for nodal fields
# filename output_frequency
fix_modify AtC output atc_fe_output 100

run 1000
```

likewise for this post-processing example:

```plaintext
# ... commands to create and initialize the MD system

# initial fix to designate post-processing and the group to apply it to
```

(continues on next page)
# no material file is allowed nor required
fix AtC internal atc hardy

# for hardy fix, specific kernel function (function type and range) to # be used as a_ localization function
fix AtC kernel quartic_sphere 10.0

# create a uniform 1 x 1 x 1 mesh that covers region contain the group
# with periodicity this effectively creates a system average
fix_modify AtC mesh create 1 1 1 box p p p

# change from default lagrangian map to eulerian
# refreshed every 100 steps
fix_modify AtC atom_element_map eulerian 100

# start with no field defined
# add mass density, potential energy density, stress and temperature
fix_modify AtC fields add density energy stress temperature

# create an output stream for nodal fields
# filename output_frequency
fix_modify AtC output nvtFE 100 text

run 1000

the mesh’s linear interpolation functions can be used as the localization function by using the field option:

```plaintext
fix AtC internal atc field
fix_modify AtC mesh create 1 1 1 box p p p
```

Note coupling and post-processing can be combined in the same simulations using separate fixes.

### 18.7.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. The fix_modify options relevant to this fix are listed below. No global scalar or vector or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

### 18.7.5 Restrictions

Thermal and two_temperature (coupling) types use a Verlet time-integration algorithm. The hardy type does not contain its own time-integrator and must be used with a separate fix that does contain one, e.g. nve, nvt, etc. In addition, currently:

- the coupling is restricted to thermal physics
- the FE computations are done in serial on each processor.
18.7.6 Related commands

After specifying this fix in your input script, several other fix_modify commands are used to setup the problem, e.g. define the finite element mesh and prescribe initial and boundary conditions.

fix_modify commands for setup:

- fix_modify AtC mesh create
- fix_modify AtC mesh quadrature
- fix_modify AtC mesh read
- fix_modify AtC mesh write
- fix_modify AtC mesh create_nodeset

18.7. fix atc command
18.8 fix atom/swap command

18.8.1 Syntax

```
fix ID group-ID atom/swap N X seed T keyword values ...
```

- ID, group-ID are documented in `fix` command
- atom/swap = style name of this fix command
- N = invoke this fix every N steps
- X = number of swaps to attempt every N steps
- seed = random # seed (positive integer)
- T = scaling temperature of the MC swaps (temperature units)
- one or more keyword/value pairs may be appended to args
- keyword = types or mu or ke or semi-grand or region
  - `types` values = two or more atom types
  - `mu` values = chemical potential of swap types (energy units)
  - `ke` value = no or yes
    - no = no conservation of kinetic energy after atom swaps
    - yes = kinetic energy is conserved after atom swaps
  - `semi-grand` value = no or yes
    - no = particle type counts and fractions conserved
    - yes = semi-grand canonical ensemble, particle fractions not conserved
  - `region` value = region-ID
    - region-ID = ID of region to use as an exchange/move volume

18.8.2 Examples

```
fix 2 all atom/swap 1 1 29494 300.0 ke no types 1 2
fix myFix all atom/swap 100 1 12345 298.0 region my_swap_region types 5 6
fix SGMC all atom/swap 1 100 345 1.0 semi-grand yes types 1 2 3 mu 0.0 4.3 -5.0
```

18.8.3 Description

This fix performs Monte Carlo swaps of atoms of one given atom type with atoms of the other given atom types. The specified T is used in the Metropolis criterion dictating swap probabilities.

Perform X swaps of atoms of one type with atoms of another type according to a Monte Carlo probability. Swap candidates must be in the fix group, must be in the region (if specified), and must be of one of the listed types. Swaps are attempted between candidates that are chosen randomly with equal probability among the candidate atoms. Swaps are not attempted between atoms of the same type since nothing would happen.

All atoms in the simulation domain can be moved using regular time integration displacements, e.g. via `fix nvt`, resulting in a hybrid MC+MD simulation. A smaller-than-usual timestep size may be needed when running such a hybrid simulation, especially if the swapped atoms are not well equilibrated.

The `types` keyword is required. At least two atom types must be specified.

The `ke` keyword can be set to `no` to turn off kinetic energy conservation for swaps. The default is `yes`, which means that swapped atoms have their velocities scaled by the ratio of the masses of the swapped atom types. This ensures
that the kinetic energy of each atom is the same after the swap as it was before the swap, even though the atom masses have changed.

The semi-grand keyword can be set to yes to switch to the semi-grand canonical ensemble as discussed in (Sadigh). This means that the total number of each particle type does not need to be conserved. The default is no, which means that the only kind of swap allowed exchanges an atom of one type with an atom of a different given type. In other words, the relative mole fractions of the swapped atoms remains constant. Whereas in the semi-grand canonical ensemble, the composition of the system can change. Note that when using semi-grand, atoms in the fix group whose type is not listed in the types keyword are ineligible for attempted conversion. An attempt is made to switch the selected atom (if eligible) to one of the other listed types with equal probability. Acceptance of each attempt depends upon the Metropolis criterion.

The mu keyword allows users to specify chemical potentials. This is required and allowed only when using semi-grand. All chemical potentials are absolute, so there is one for each swap type listed following the types keyword. In semi-grand canonical ensemble simulations the chemical composition of the system is controlled by the difference in these values. So shifting all values by a constant amount will have no effect on the simulation.

This command may optionally use the region keyword to define swap volume. The specified region must have been previously defined with a region command. It must be defined with side = in. Swap attempts occur only between atoms that are both within the specified region. Swaps are not otherwise attempted.

You should ensure you do not swap atoms belonging to a molecule, or LAMMPS will soon generate an error when it tries to find those atoms. LAMMPS will warn you if any of the atoms eligible for swapping have a non-zero molecule ID, but does not check for this at the time of swapping.

If not using semi-grand this fix checks to ensure all atoms of the given types have the same atomic charge. LAMMPS does not enforce this in general, but it is needed for this fix to simplify the swapping procedure. Successful swaps will swap the atom type and charge of the swapped atoms. Conversely, when using semi-grand, it is assumed that all the atom types involved in switches have the same charge. Otherwise, charge would not be conserved. As a consequence, no checks on atomic charges are performed, and successful switches update the atom type but not the atom charge. While it is possible to use semi-grand with groups of atoms that have different charges, these charges will not be changed when the atom types change.

Since this fix computes total potential energies before and after proposed swaps, so even complicated potential energy calculations are OK, including the following:

- long-range electrostatics (kspace)
- many body pair styles
- hybrid pair styles
- eam pair styles
- triclinic systems
- need to include potential energy contributions from other fixes

Some fixes have an associated potential energy. Examples of such fixes include: efield, gravity, addforce, langevin, restrain, temp/berendsen, temp/rescale, and wall fixes. For that energy to be included in the total potential energy of the system (the quantity used when performing GCMC moves), you MUST enable the fix_modify energy option for that fix. The doc pages for individual fix commands specify if this should be done.
18.8.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the fix to binary restart files. This includes information about the random number generator seed, the next timestep for MC exchanges, the number of exchange attempts and successes etc. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** For this to work correctly, the timestep must not be changed after reading the restart with reset_timestep. The fix will try to detect it and stop with an error.

None of the fix_modify options are relevant to this fix.

This fix computes a global vector of length 2, which can be accessed by various output commands. The vector values are the following global cumulative quantities:

- 1 = swap attempts
- 2 = swap successes

The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.8.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.8.6 Related commands

fix nvt, neighbor, fix deposit, fix evaporate, delete_atoms, fix gcmc

18.8.7 Default

The option defaults are ke = yes, semi-grand = no, mu = 0.0 for all atom types.

18.9 fix ave/atom command

18.9.1 Syntax

```
fix ID group-ID ave/atom Nevery Nrepeat Nfreq value1 value2 ...
```

- ID, group-ID are documented in fix command
- ave/atom = style name of this fix command
- Nevery = use input values every this many timesteps
• \( N_{\text{repeat}} \) = \# of times to use input values for calculating averages
• \( N_{\text{freq}} \) = calculate averages every this many timesteps one or more input values can be listed
• value = \( x, y, z, vx, vy, vz, fx, fy, fz, c_{\text{ID}}, c_{\text{ID}[i]}, f_{\text{ID}}, f_{\text{ID}[i]}, v_{\text{name}} \)

\( x, y, z, vx, vy, vz, fx, fy, fz \) = atom attribute (position, velocity, force component)
\( c_{\text{ID}} \) = per-atom vector calculated by a compute with ID
\( c_{\text{ID}[i]} \) = \( i \)th column of per-atom array calculated by a compute with ID, \( i \) can include wildcard (see below)
\( f_{\text{ID}} \) = per-atom vector calculated by a fix with ID
\( f_{\text{ID}[i]} \) = \( i \)th column of per-atom array calculated by a fix with ID, \( i \) can include wildcard (see below)
\( v_{\text{name}} \) = per-atom vector calculated by an atom-style variable with name

18.9.2 Examples

```
fix 1 all ave/atom 1 100 100 vx vy vz
fix 1 all ave/atom 10 20 1000 c_my_stress[1]
fix 1 all ave/atom 10 20 1000 c_my_stress[*]
```

18.9.3 Description

Use one or more per-atom vectors as inputs every few timesteps, and average them atom by atom over longer timescales. The resulting per-atom averages can be used by other output commands such as the fix ave/chunk or dump custom commands.

The group specified with the command means only atoms within the group have their averages computed. Results are set to 0.0 for atoms not in the group.

Each input value can be an atom attribute (position, velocity, force component) or can be the result of a compute or fix or the evaluation of an atom-style variable. In the latter cases, the compute, fix, or variable must produce a per-atom vector, not a global quantity or local quantity. If you wish to time-average global quantities from a compute, fix, or variable, then see the fix ave/time command.

Each per-atom value of each input vector is averaged independently.

Computes that produce per-atom vectors or arrays are those which have the word atom in their style name. See the docs pages for individual fixes to determine which ones produce per-atom vectors or arrays. Variables of style atom are the only ones that can be used with this fix since they produce per-atom vectors.

Note that for values from a compute or fix, the bracketed index \( I \) can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “\*” or “\*n” or “n*” or “m*n”. If \( N \) = the size of the vector (for mode = scalar) or the number of columns in the array (for mode = vector), then an asterisk with no numeric values means all indices from 1 to \( N \). A leading asterisk means all indices from 1 to \( n \) (inclusive). A trailing asterisk means all indices from \( n \) to \( N \) (inclusive). A middle asterisk means all indices from \( m \) to \( n \) (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 fix ave/atom commands are equivalent, since the compute stress/atom command creates a per-atom array with 6 columns:

```
compute my_stress all stress/atom NULL
fix 1 all ave/atom 10 20 1000 c_my_stress[*]
```
The `Nevery`, `Nrepeat`, and `Nfreq` arguments specify on what timesteps the input values will be used in order to contribute to the average. The final averaged quantities are generated on timesteps that are a multiple of `Nfreq`. The average is over `Nrepeat` quantities, computed in the preceding portion of the simulation every `Nevery` timesteps. `Nfreq` must be a multiple of `Nevery` and `Nevery` must be non-zero even if `Nrepeat` is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. `Nrepeat*Nevery` cannot exceed `Nfreq`.

For example, if `Nevery=2`, `Nrepeat=6`, and `Nfreq=100`, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc.

The atom attribute values (x,y,z,vx,vy,vz,fx, fy, fz) are self-explanatory. Note that other atom attributes can be used as inputs to this fix by using the `compute property/atom` command and then specifying an input value from that compute.

**Note:** The x,y,z attributes are values that are re-wrapped inside the periodic box whenever an atom crosses a periodic boundary. Thus if you time average an atom that spends half its time on either side of the periodic box, you will get a value in the middle of the box. If this is not what you want, consider averaging unwrapped coordinates, which can be provided by the `compute property/atom` command via its xu,yu,zu attributes.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. If no bracketed term is appended, the per-atom vector calculated by the compute is used. If a bracketed term containing an index I is appended, the Ith column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. If no bracketed term is appended, the per-atom vector calculated by the fix is used. If a bracketed term containing an index I is appended, the Ith column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with `Nevery`, else an error will result. Users can also write code for their own fix styles and *add them to LAMMPS*. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script as an atom-style variable. Variables of style `atom` can reference thermodynamic keywords, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to time average.

---

**18.9.4 Restart, fix modify, output, run start/stop, minimize info**

No information about this fix is written to binary restart files. None of the `fix modify` options are relevant to this fix. No global scalar or vector quantities are stored by this fix for access by various output commands.

This fix produces a per-atom vector or array which can be accessed by various output commands. A vector is produced if only a single quantity is averaged by this fix. If two or more quantities are averaged, then an array of values is produced. The per-atom values can only be accessed on timesteps that are multiples of `Nfreq` since that is when averaging is performed.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

title2 arg = string
  string = text to print as 2nd line of output file
title3 arg = string
  string = text to print as 3rd line of output file

18.10.2 Examples

```plaintext
fix 1 all ave/chunk 10000 1 10000 binchunk c_myCentro title1 "My output values"
fix 1 flow ave/chunk 100 10 1000 molchunk vx vz norm sample file vel.profile
fix 1 flow ave/chunk 100 5 1000 binchunk density/mass ave running
fix 1 flow ave/chunk 100 5 1000 binchunk density/mass ave running
```

NOTE:

If you are trying to replace a deprecated fix ave/spatial command with the newer, more flexible fix ave/chunk and compute chunk/atom commands, you simply need to split the fix ave/spatial arguments across the two new commands. For example, this command:

```plaintext
fix 1 flow ave/spatial 100 10 1000 y 0.0 1.0 vx vz norm sample file vel.profile
```

could be replaced by:

```plaintext
compute ccl flow chunk/atom bin/1d y 0.0 1.0
fix 1 flow ave/chunk 100 10 1000 ccl vx vz norm sample file vel.profile
```
18.10.3 Description

Use one or more per-atom vectors as inputs every few timesteps, sum the values over the atoms in each chunk at each timestep, then average the per-chunk values over longer timescales. The resulting chunk averages can be used by other output commands such as thermo_style custom, and can also be written to a file.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom doc page and the Howto chunk doc page for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

Note that only atoms in the specified group contribute to the summing and averaging calculations. The compute chunk/atom command defines its own group as well as an optional region. Atoms will have a chunk ID = 0, meaning they belong to no chunk, if they are not in that group or region. Thus you can specify the “all” group for this command if you simply want to use the chunk definitions provided by chunkID.

Each specified per-atom value can be an atom attribute (position, velocity, force component), a mass or number density, or the result of a compute or fix or the evaluation of an atom-style variable. In the latter cases, the compute, fix, or variable must produce a per-atom quantity, not a global quantity. Note that the compute property/atom command provides access to any attribute defined and stored by atoms. If you wish to time-average global quantities from a compute, fix, or variable, then see the fix ave/time command.

The per-atom values of each input vector are summed and averaged independently of the per-atom values in other input vectors.

Computes that produce per-atom quantities are those which have the word atom in their style name. See the doc pages for individual fixes to determine which ones produce per-atom quantities. Variables of style atom are the only ones that can be used with this fix since all other styles of variable produce global quantities.

Note that for values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the size of the vector (for mode = scalar) or the number of columns in the array (for mode = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 fix ave/chunk commands are equivalent, since the compute property/atom command creates, in this case, a per-atom array with 3 columns:

```
compute myAng all property/atom angmomx angmomy angmomz
fix 1 all ave/chunk 100 1 100 ccl c_myAng[*] file tmp.angmom
```

Note: This fix works by creating an array of size Nchunk by Nvalues on each processor. Nchunk is the number of chunks which is defined by the compute chunk/atom command. Nvalues is the number of input values specified. Each processor loops over its atoms, tallying its values to the appropriate chunk. Then the entire array is summed across all processors. This means that using a large number of chunks will incur an overhead in memory and computational cost (summing across processors), so be careful to define a reasonable number of chunks.

The Nevery, Nrepeat, and Nfreq arguments specify on what timesteps the input values will be accessed and contribute to the average. The final averaged quantities are generated on timesteps that are a multiples of Nfreq. The average is over Nrepeat quantities, computed in the preceding portion of the simulation every Nevery timesteps. Nfreq must be a multiple of Nevery and Nevery must be non-zero even if Nrepeat is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. Nrepeat*Nevery can not exceed Nfreq.
For example, if \( N_{\text{every}} = 2 \), \( N_{\text{repeat}} = 6 \), and \( N_{\text{freq}} = 100 \), then values on timesteps 90, 92, 94, 96, 98, 100 will be used to compute the final average on timestep 100. Similarly for timesteps 190, 192, 194, 196, 198, 200 on timestep 200, etc. If \( N_{\text{repeat}} = 1 \) and \( N_{\text{freq}} = 100 \), then no time averaging is done; values are simply generated on timesteps 100, 200, etc.

Each input value can also be averaged over the atoms in each chunk. The way the averaging is done across the \( N_{\text{repeat}} \) timesteps to produce output on the \( N_{\text{freq}} \) timesteps, and across multiple \( N_{\text{freq}} \) outputs, is determined by the \( \text{norm} \) and \( \text{ave} \) keyword settings, as discussed below.

**Note:** To perform per-chunk averaging within a \( N_{\text{freq}} \) time window, the number of chunks \( N_{\text{chunk}} \) defined by the \text{compute chunk/atom} command must remain constant. If the \( \text{ave} \) keyword is set to \text{running} or \text{window} then \( N_{\text{chunk}} \) must remain constant for the duration of the simulation. This fix forces the chunk/atom compute specified by chunkID to hold \( N_{\text{chunk}} \) constant for the appropriate time windows, by not allowing it to re-calculate \( N_{\text{chunk}} \), which can also affect how it assigns chunk IDs to atoms. This is particularly important to understand if the chunks defined by the \text{compute chunk/atom} command are spatial bins. If its \text{units} keyword is set to \text{box} or \text{lattice}, then the number of bins \( N_{\text{chunk}} \) and size of each bin will be fixed over the \( N_{\text{freq}} \) time window, which can affect which atoms are discarded if the simulation box size changes. If its \text{units} keyword is set to \text{reduced}, then the number of bins \( N_{\text{chunk}} \) will still be fixed, but the size of each bin can vary at each timestep if the simulation box size changes, e.g. for an NPT simulation.

The atom attribute values (\( v_x, v_y, v_z, f_x, f_y, f_z \)) are self-explanatory. As noted above, any other atom attributes can be used as input values to this fix by using the \text{compute property/atom} command and then specifying an input value from that compute.

The \text{density/number} value means the number density is computed for each chunk, i.e. number/volume. The \text{density/mass} value means the mass density is computed for each chunk, i.e. total-mass/volume. The output values are in units of 1/volume or density (mass/volume). See the \text{units} command doc page for the definition of density for each choice of units, e.g. gram/cm\(^3\). If the chunks defined by the \text{compute chunk/atom} command are spatial bins, the volume is the bin volume. Otherwise it is the volume of the entire simulation box.

The \text{temp} value means the temperature is computed for each chunk, by the formula \( KE = DOF/2 \ k \ T \), where \( KE = \) total kinetic energy of the chunk of atoms (sum of \( 1/2 \ m \ v^2 \)), \( DOF = \) the total number of degrees of freedom for all atoms in the chunk, \( k = \) Boltzmann constant, and \( T = \) temperature.

The \( DOF \) is calculated as \( N \cdot \text{adof} + \text{cdof} \), where \( N = \) number of atoms in the chunk, \( \text{adof} = \) degrees of freedom per atom, and \( \text{cdof} = \) degrees of freedom per chunk. By default \( \text{adof} = 2 \) or \( 3 = \) dimensionality of system, as set via the \text{dimension} command, and \( \text{cdof} = 0.0 \). This gives the usual formula for temperature.

Note that currently this temperature only includes translational degrees of freedom for each atom. No rotational degrees of freedom are included for finite-size particles. Also no degrees of freedom are subtracted for any velocity bias or constraints that are applied, such as \text{compute temp/partial}, or \text{fix shake} or \text{fix rigid}. This is because those degrees of freedom (e.g. a constrained bond) could apply to sets of atoms that are both included and excluded from a specific chunk, and hence the concept is somewhat ill-defined. In some cases, you can use the \text{adof} and \text{cdof} keywords to adjust the calculated degrees of freedom appropriately, as explained below.

Also note that a bias can be subtracted from atom velocities before they are used in the above formula for \( KE \), by using the \text{bias} keyword. This allows, for example, a thermal temperature to be computed after removal of a flow velocity profile.

Note that the per-chunk temperature calculated by this fix and the \text{compute temp/chunk} command can be different. The compute calculates the temperature for each chunk for a single snapshot. This fix can do that but can also time average those values over many snapshots, or it can compute a temperature as if the atoms in the chunk on different timesteps were collected together as one set of atoms to calculate their temperature. The compute allows the center-of-mass velocity of each chunk to be subtracted before calculating the temperature; this fix does not.

If a value begins with “\( c_\)”, a compute ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the \( I \)th column of the per-atom array calculated by the compute is used. Users can also write code for their
own compute styles and add them to LAMMPS. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with Nevery, else an error results. Users can also write code for their own fix styles and add them to LAMMPS. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. Variables of style atom can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to average within chunks.

Additional optional keywords also affect the operation of this fix and its outputs.

The \textit{norm} keyword affects how averaging is done for the per-chunk values that are output every $Nfreq$ timesteps.

If the \textit{norm} setting is \textit{all}, which is the default, a chunk value is summed over all atoms in all $Nrepeat$ samples, as is the count of atoms in the chunk. The averaged output value for the chunk on the $Nfreq$ timesteps is Total-sum / Total-count. In other words it is an average over atoms across the entire $Nfreq$ timescale. For the \textit{density/number} and \textit{density/mass} values, the volume (bin volume or system volume) used in the final normalization will be the volume at the final $Nfreq$ timestep.

If the \textit{norm} setting is \textit{sample}, the chunk value is summed over atoms for each sample, as is the count, and an “average sample value” is computed for each sample, i.e. Sample-sum / Sample-count. The output value for the chunk on the $Nfreq$ timesteps is the average of the $Nrepeat$ “average sample values”, i.e. the sum of $Nrepeat$ “average sample values” divided by $Nrepeat$. In other words it is an average of an average. For the \textit{density/number} and \textit{density/mass} values, the volume (bin volume or system volume) used in the per-sample normalization will be the current volume at each sampling step.

If the \textit{norm} setting is \textit{none}, a similar computation as for the \textit{sample} setting is done, except the individual “average sample values” are “summed sample values”. A summed sample value is simply the chunk value summed over atoms in the sample, without dividing by the number of atoms in the sample. The output value for the chunk on the $Nfreq$ timesteps is the average of the $Nrepeat$ “summed sample values”, i.e. the sum of $Nrepeat$ “summed sample values” divided by $Nrepeat$. For the \textit{density/number} and \textit{density/mass} values, the volume (bin volume or system volume) used in the per-sample sum normalization will be the current volume at each sampling step.

The \textit{ave} keyword determines how the per-chunk values produced every $Nfreq$ steps are averaged with values produced on previous steps that were multiples of $Nfreq$, before they are accessed by another output command or written to a file.

If the \textit{ave} setting is \textit{one}, which is the default, then the chunk values produced on timesteps that are multiples of $Nfreq$ are independent of each other; they are output as-is without further averaging.

If the \textit{ave} setting is \textit{running}, then the chunk values produced on timesteps that are multiples of $Nfreq$ are summed and averaged in a cumulative sense before being output. Each output chunk value is thus the average of the chunk value produced on that timestep with all preceding values for the same chunk. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the \textit{unfix} command, or re-defining the fix by re-specifying it.

If the \textit{ave} setting is \textit{window}, then the chunk values produced on timesteps that are multiples of $Nfreq$ are summed and averaged within a moving “window” of time, so that the last $M$ values for the same chunk are used to produce the output. E.g. if $M = 3$ and $Nfreq = 1000$, then the output on step 10000 will be the average of the individual chunk values on steps 8000,9000,10000. Outputs on early steps will average over less than $M$ values if they are not available.

The \textit{bias} keyword specifies the ID of a temperature compute that removes a “bias” velocity from each atom, specified as \textit{bias-ID}. It is only used when the \textit{temp} value is calculated, to compute the thermal temperature of each chunk after
the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile. See the doc pages for individual computes that calculate a temperature to see which ones implement a bias.

The $a dof$ and $c dof$ keywords define the values used in the degree of freedom (DOF) formula described above for temperature calculation for each chunk. They are only used when the $temp$ value is calculated. They can be used to calculate a more appropriate temperature for some kinds of chunks. Here are 3 examples:

If spatially binned chunks contain some number of water molecules and $fix\ shake$ is used to make each molecule rigid, then you could calculate a temperature with 6 degrees of freedom (DOF) (3 translational, 3 rotational) per molecule by setting $a dof$ to 2.0.

If $compute\ temp/partial$ is used with the bias keyword to only allow the x component of velocity to contribute to the temperature, then $a dof$ = 1.0 would be appropriate.

If each chunk consists of a large molecule, with some number of its bonds constrained by $fix\ shake$ or the entire molecule by $fix\ rigid/small$, $a dof$ = 0.0 and $c dof$ could be set to the remaining degrees of freedom for the entire molecule (entire chunk in this case), e.g. 6 for 3d, or 3 for 2d, for a rigid molecule.

The $file$ keyword allows a filename to be specified. Every $Nfreq$ timesteps, a section of chunk info will be written to a text file in the following format. A line with the timestep and number of chunks is written. Then one line per chunk is written, containing the chunk ID (1-Nchunk), an optional original ID value, optional coordinate values for chunks that represent spatial bins, the number of atoms in the chunk, and one or more calculated values. More explanation of the optional values is given below. The number of values in each line corresponds to the number of values specified in the $fix\ ave/chunk$ command. The number of atoms and the value(s) are summed or average quantities, as explained above.

The overwrite keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the ave running setting.

The format keyword sets the numeric format of each value when it is printed to a file via the file keyword. Note that all values are floating point quantities. The default format is %g. You can specify a higher precision if desired, e.g. %20.16g.

The $title1$ and $title2$ and $title3$ keywords allow specification of the strings that will be printed as the first 3 lines of the output file, assuming the file keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:

```
# Chunk-averaged data for fix ID and group name
# Timestep Number-of-chunks
# Chunk (OrigID) (Coord1) (Coord2) (Coord3) Ncount value1 value2 ...
```

In the first line, ID and name are replaced with the fix-ID and group name. The second line describes the two values that are printed at the first of each section of output. In the third line the values are replaced with the appropriate value names, e.g. fx or c_myCompute[2].

The words in parenthesis only appear with corresponding columns if the chunk style specified for the $compute\ chunk/atom$ command supports them. The OrigID column is only used if the compress keyword was set to yes for the $compute\ chunk/atom$ command. This means that the original chunk IDs (e.g. molecule IDs) will have been compressed to remove chunk IDs with no atoms assigned to them. Thus a compressed chunk ID of 3 may correspond to an original chunk ID or molecule ID of 415. The OrigID column will list 415 for the third chunk.

The CoordN columns only appear if a binning style was used in the $compute\ chunk/atom$ command. For bin/1d, bin/2d, and bin/3d styles the column values are the center point of the bin in the corresponding dimension. Just Coord1 is used for bin/1d, Coord2 is added for bin/2d, Coord3 is added for bin/3d. For bin/sphere, just Coord1 is used, and it is the radial coordinate. For bin/cylinder, Coord1 and Coord2 are used. Coord1 is the radial coordinate (away from the cylinder axis), and coord2 is the coordinate along the cylinder axis.
Note that if the value of the units keyword used in the compute chunk/atom command is box or lattice, the coordinate values will be in distance units. If the value of the units keyword is reduced, the coordinate values will be in unitless reduced units (0-1). This is not true for the Coord1 value of style bin/sphere or bin/cylinder which both represent radial dimensions. Those values are always in distance units.

18.10.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes a global array of values which can be accessed by various output commands. The values can only be accessed on timesteps that are multiples of Nfreq since that is when averaging is performed. The global array has # of rows = the number of chunks Nchunk as calculated by the specified compute chunk/atom command. The # of columns = M+1+Nvalues, where M = 1 to 4, depending on whether the optional columns for OrigID and CoordN are used, as explained above. Following the optional columns, the next column contains the count of atoms in the chunk, and the remaining columns are the Nvalue quantities. When the array is accessed with a row I that exceeds the current number of chunks, than a 0.0 is returned by the fix instead of an error, since the number of chunks can vary as a simulation runs depending on how that value is computed by the compute chunk/atom command.

The array values calculated by this fix are treated as “intensive”, since they are typically already normalized by the count of atoms in each chunk.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

  title3 arg = string
  string = text to print as 3rd line of output file

18.11.2 Examples

```bash
fix 1 all ave/correlate 5 100 1000 c_myTemp file temp.correlate
fix 1 all ave/correlate 1 50 10000 &
   type upper ave running title1 "My correlation data"
fix 1 all ave/correlate 1 50 10000 c_thermo_press[*]
```
18.11.3 Description

Use one or more global scalar values as inputs every few timesteps, calculate time correlations between them at varying time intervals, and average the correlation data over longer timescales. The resulting correlation values can be time integrated by variables or used by other output commands such as thermo_style custom, and can also be written to a file. See the fix ave/correlate/long command for an alternate method for computing correlation functions efficiently over very long time windows.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a compute or fix or the evaluation of an equal-style or vector-style variable. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity. If you wish to spatial- or time-average or histogram per-atom quantities from a compute, fix, or variable, then see the fix ave/chunk, fix ave/atom, or fix ave/histo commands. If you wish to convert a per-atom quantity into a single global value, see the compute reduce command.

The input values must either be all scalars. What kinds of correlations between input values are calculated is determined by the type keyword as discussed below.

Computes that produce global quantities are those which do not have the word atom in their style name. Only a few fixes produce global quantities. See the doc pages for individual fixes for info on which ones produce such values. Variables of style equal and vector are the only ones that can be used with this fix. Variables of style atom cannot be used, since they produce per-atom values.

Note that for values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the size of the vector (for mode = scalar) or the number of columns in the array (for mode = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive). Using a wildcard is the same as if the individual elements of the vector had been listed one by one. E.g. these 2 fix ave/correlate commands are equivalent, since the compute pressure command creates a global vector with 6 values.

```
compute myPress all pressure NULL
fix 1 all ave/correlate 1 50 10000 c_myPress[*]
fix 1 all ave/correlate 1 50 10000 &
```

The Nevery, Nrepeat, and Nfreq arguments specify on what timesteps the input values will be used to calculate correlation data. The input values are sampled every Nevery timesteps. The correlation data for the preceding samples is computed on timesteps that are a multiple of Nfreq. Consider a set of samples from some initial time up to an output timestep. The initial time could be the beginning of the simulation or the last output time; see the ave keyword for options. For the set of samples, the correlation value Cij is calculated as:

\[
C_{ij}(\Delta t) = \text{ave}(V_i(t) \times V_j(t+\Delta t))
\]

which is the correlation value between input values Vi and Vj, separated by time delta. Note that the second value Vj in the pair is always the one sampled at the later time. The ave() represents an average over every pair of samples in the set that are separated by time delta. The maximum delta used is of size (Nrepeat-1)*Nevery. Thus the correlation between a pair of input values yields Nrepeat correlation datums:

\[
C_{ij}(0), C_{ij}(\text{Nevery}), C_{ij}(2\times\text{Nevery}), \ldots, C_{ij}((Nrepeat-1)\times\text{Nevery})
\]

For example, if Nevery=5, Nrepeat=6, and Nfreq=100, then values on timesteps 0,5,10,15,…,100 will be used to compute the final averages on timestep 100. Six averages will be computed: Cij(0), Cij(5), Cij(10), Cij(15), Cij(20),
and Cij(25). Cij(10) on timestep 100 will be the average of 19 samples, namely Vi(0)*Vj(10), Vi(5)*Vj(15), Vi(10)*Vj(20), Vi(15)*Vj(25), . . . , Vi(85)*Vj(95), Vi(90)*Vj(100).

Nfreq must be a multiple of Nevery; Nevery and Nrepeat must be non-zero. Also, if the ave keyword is set to one which is the default, then Nfreq >= (Nrepeat-1)*Nevery is required.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the Ith element of the global vector calculated by the compute is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a compute reduce command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by fix ave/correlate. Or it can be a compute defined not in your input script, but by thermodynamic output or other fixes such as fix nvt or fix temp/rescale. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and add them to LAMMPS.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that some fixes only produce their values on certain timesteps, which must be compatible with Nevery, else an error will result. Users can also write code for their own fix styles and add them to LAMMPS.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. Only equal-style or vector-style variables can be referenced; the latter requires a bracketed term to specify the Ith element of the vector calculated by the variable. See the variable command for details. Note that variables of style equal or vector define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to time correlate.

Additional optional keywords also affect the operation of this fix.

The type keyword determines which pairs of input values are correlated with each other. For N input values Vi, for i = 1 to N, let the number of pairs = Npair. Note that the second value in the pair Vi(t)*Vj(t+delta) is always the one sampled at the later time.

• If type is set to auto then each input value is correlated with itself. I.e. Cii = Vi*Vi, for i = 1 to N, so Npair = N.
• If type is set to upper then each input value is correlated with every succeeding value. I.e. Cij = Vi*Vj, for i < j, so Npair = N*(N-1)/2.
• If type is set to lower then each input value is correlated with every preceding value. I.e. Cij = Vi*Vj, for i > j, so Npair = N*(N-1)/2.
• If type is set to auto/upper then each input value is correlated with itself and every succeeding value. I.e. Cij = Vi*Vj, for i >= j, so Npair = N*(N+1)/2.
• If type is set to auto/lower then each input value is correlated with itself and every preceding value. I.e. Cij = Vi*Vj, for i <= j, so Npair = N*(N+1)/2.
• If type is set to full then each input value is correlated with itself and every other value. I.e. Cij = Vi*Vj, for i,j = 1,N so Npair = N^2.

The ave keyword determines what happens to the accumulation of correlation samples every Nfreq timesteps. If the ave setting is one, then the accumulation is restarted or zeroed every Nfreq timesteps. Thus the outputs on successive Nfreq timesteps are essentially independent of each other. The exception is that the Cij(0) = Vi(T)*Vj(T) value at a timestep T, where T is a multiple of Nfreq, contributes to the correlation output both at time T and at time T+Nfreq.
If the *ave setting is running*, then the accumulation is never zeroed. Thus the output of correlation data at any timestep is the average over samples accumulated every *Nevery* steps since the fix was defined. It can only be restarted by deleting the fix via the *unfix* command, or by re-defining the fix by re-specifying it.

The *start* keyword specifies what timestep the accumulation of correlation samples will begin on. The default is step 0. Setting it to a larger value can avoid adding non-equilibrated data to the correlation averages.

The *prefactor* keyword specifies a constant which will be used as a multiplier on the correlation data after it is averaged. It is effectively a scale factor on $V_i*V_j$, which can be used to account for the size of the time window or other unit conversions.

The *file* keyword allows a filename to be specified. Every *Nfreq* steps, an array of correlation data is written to the file. The number of rows is *Nrepeat*, as described above. The number of columns is the Npair+2, also as described above. Thus the file ends up to be a series of these array sections.

The *overwrite* keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the *ave running* setting.

The *title1* and *title2* and *title3* keywords allow specification of the strings that will be printed as the first 3 lines of the output file, assuming the *file* keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:

```
# Time-correlated data for fix ID
# TimeStep Number-of-time-windows
# Index TimeDelta Ncount valueI*valueJ valueI*valueJ ...
```

In the first line, ID is replaced with the fix-ID. The second line describes the two values that are printed at the first of each section of output. In the third line the value pairs are replaced with the appropriate fields from the fix ave/correlate command.

Let $S_{ij} = \text{a set of time correlation data for input values } I \text{ and } J, \text{ namely the } N_{repeat} \text{ values:}$

$S_{ij} = C_{ij}(0), C_{ij}(N_{every}), C_{ij}(2*N_{every}), \ldots, C_{ij}(N_{repeat}-1)*N_{every})$

As explained below, these datums are output as one column of a global array, which is effectively the correlation matrix.

The *trap* function defined for *equal-style variables* can be used to perform a time integration of this vector of datums, using a trapezoidal rule. This is useful for calculating various quantities which can be derived from time correlation data. If a normalization factor is needed for the time integration, it can be included in the variable formula or via the *prefactor* keyword.

---

### 18.11.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix.

This fix computes a global array of values which can be accessed by various *output commands*. The values can only be accessed on timesteps that are multiples of *Nfreq* since that is when averaging is performed. The global array has # of rows = *Nrepeat* and # of columns = Npair+2. The first column has the time delta (in timesteps) between the pairs of input values used to calculate the correlation, as described above. The second column has the number of samples contributing to the correlation average, as described above. The remaining Npair columns are for IJ pairs of the N input values, as determined by the *type* keyword, as described above.

- For *type = auto*, the Npair = N columns are ordered: C11, C22, \ldots, CNN.
• For type = upper, the Npair = N*(N-1)/2 columns are ordered: C12, C13, ..., C1N, C23, ..., C2N, C34, ..., CN-1N.
• For type = lower, the Npair = N*(N-1)/2 columns are ordered: C21, C31, C32, C41, C42, C43, ..., CN1, CN2, ..., CNN-1, CNN.
• For type = auto/upper, the Npair = N*(N+1)/2 columns are ordered: C11, C12, C13, ..., C1N, C22, C23, ..., C2N, C33, C34, ..., CN-1N, CNN.
• For type = auto/lower, the Npair = N*(N+1)/2 columns are ordered: C11, C21, C22, C31, C32, C33, C41, ..., C44, CN1, CN2, ..., CNN-1, CNN.
• For type = full, the Npair = N^2 columns are ordered: C11, C12, ..., C1N, C21, C22, ..., C2N, C31, ..., C3N, ..., CN1, ..., CNN-1, CNN.

The array values calculated by this fix are treated as intensive. If you need to divide them by the number of atoms, you must do this in a later processing step, e.g. when using them in a variable.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

    Ncorrelators = number of correlators to store
  nlen args = Nlen
    Nlen = length of each correlator
  ncount args = Ncount
    Ncount = number of values over which successive correlators are averaged

**18.12.2 Examples**

```latex
fix 1 all ave/correlate/long 5 1000 c_myTemp file temp.correlate
fix 1 all ave/correlate/long 1 10000 &
type upper title1 "My correlation data" nlen 15 ncount 3
```

**18.12.3 Description**

This fix is similar in spirit and syntax to the fix `ave/correlate`. However, this fix allows the efficient calculation of time correlation functions on-the-fly over extremely long time windows with little additional CPU overhead, using a multiple-tau method (Ramirez) that decreases the resolution of the stored correlation function with time. It is not a full drop-in replacement.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a compute or fix or the evaluation of an equal-style variable. See the fix `ave/correlate` doc page for details.
The *Nevery* and *Nfreq* arguments specify on what timesteps the input values will be used to calculate correlation data, and the frequency with which the time correlation functions will be output to a file. Note that there is no *Nrepeat* argument, unlike the *fix ave/correlate* command.

The optional keywords *ncorr*, *nlen*, and *ncount* are unique to this command and determine the number of correlation points calculated and the memory and CPU overhead used by this calculation. *Nlen* and *ncount* determine the amount of averaging done at longer correlation times. The default values *nlen*=16, *ncount*=2 ensure that the systematic error of the multiple-tau correlator is always below the level of the statistical error of a typical simulation (which depends on the ensemble size and the simulation length).

The maximum correlation time (in time steps) that can be reached is given by the formula \((nlen-1) * ncount^{(ncorr-1)}\). Longer correlation times are discarded and not calculated. With the default values of the parameters (ncorr=20, nlen=16 and ncount=2), this corresponds to 7864320 time steps. If longer correlation times are needed, the value of ncorr should be increased. Using nlen=16 and ncount=2, with ncorr=30, the maximum number of steps that can be correlated is 80530636808. If ncorr=40, correlation times in excess of 8e12 time steps can be calculated.

The total memory needed for each correlation pair is roughly 4*ncorr*nlen*8 bytes. With the default values of the parameters, this corresponds to about 10 KB.

For the meaning of the additional optional keywords, see the *fix ave/correlate* doc page.

### 18.12.4 Restart, *fix modify*, output, run start/stop, minimize info

Contrary to *fix ave/correlate* this fix does not provide access to its internal data to various output options. Since this fix is intended for the calculation of time correlation functions over very long MD simulations, the information about this fix is written automatically to binary restart files, so that the time correlation calculation can continue in subsequent simulations. None of the *fix modify* options are relevant to this fix.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

### 18.12.5 Restrictions

This compute is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

### 18.12.6 Related commands

*fix ave/correlate*

### 18.12.7 Default

none

The option defaults for keywords that are also keywords for the *fix ave/correlate* command are as follows: type = auto, start = 0, no file output, title 1,2 = strings as described on the *fix ave/correlate* doc page.

The option defaults for keywords unique to this command are as follows: ncorr=20, nlen=16, ncount=2.

18.13 fix ave/histo command

18.14 fix ave/histo/weight command

18.14.1 Syntax

```plaintext
fix ID group-ID style Nevery Nrepeat Nfreq lo hi Nbin value1 value2 ... keyword args 
```

- **ID, group-ID** are documented in `fix` command
- **style = ave/histo or ave/histo/weight** = style name of this fix command
- **Nevery** = use input values every this many timesteps
- **Nrepeat** = # of times to use input values for calculating histogram
- **Nfreq** = calculate histogram every this many timesteps
- **lo, hi** = lo/hi bounds within which to histogram
- **Nbin** = # of histogram bins
- one or more input values can be listed
- **value = x, y, z, vx, vy, vz, fx, fy, fz, c_ID, c_ID[N], f_ID, f_ID[N], v_name**
  - `x, y, z, vx, vy, vz, fx, fy, fz` = atom attribute (position, velocity, force component)
  - `c_ID` = scalar or vector calculated by a compute with ID
  - `c_ID[I]` = Ith component of vector or Ith column of array calculated by a compute
  - `f_ID` = scalar or vector calculated by a fix with ID
  - `f_ID[I]` = Ith component of vector or Ith column of array calculated by a fix
  - `v_name` = value(s) calculated by an equal-style or vector-style or atom-style variable with name
  - `v_name[I]` = value calculated by a vector-style variable with name
- zero or more keyword/arg pairs may be appended
- **keyword = mode or file or ave or start or beyond or overwrite or title1 or title2 or title3**
  - `mode arg = scalar or vector`
  - `scalar = all input values are scalars`
  - `vector = all input values are vectors`
  - `kind arg = global or peratom or local`
  - `file arg = filename`
  - `filename = name of file to output histogram(s) to`
  - `ave arg = one or running or window`
  - `one = output a new average value every Nfreq steps`
  - `running = output cumulative average of all previous Nfreq steps`
  - `window M = output average of M most recent Nfreq steps`
  - `start arg = Nstart`
  - `Nstart = start averaging on this timestep`
  - `beyond arg = ignore or end or extra`
  - `ignore = ignore values outside histogram lo/hi bounds`
  - `end = count values outside histogram lo/hi bounds in end bins`
  - `extra = create 2 extra bins for value outside histogram lo/hi bounds`
overwrite arg = none = overwrite output file with only latest output
title1 arg = string
  string = text to print as 1st line of output file
title2 arg = string
  string = text to print as 2nd line of output file
title3 arg = string
  string = text to print as 3rd line of output file, only for vector mode

18.14.2 Examples

```plaintext
fix 1 all ave/histo 100 5 1000 0.5 1.5 100 c_myTemp file temp.histo ave running
fix 1 all ave/histo 100 5 1000 -5 5 100 c_thermo_press[2] c_thermo_press[3] title1 "My output values"
fix 1 all ave/histo 100 5 1000 -5 5 100 c_thermo_press[*]
fix 1 all ave/histo 1 100 1000 -2.0 2.0 18 vx vy vz mode vector ave running beyond
extra
fix 1 all ave/histo/weight 1 1 1 10 1000 2000 c_XRD[1] c_XRD[2]
```

18.14.3 Description

Use one or more values as inputs every few timesteps to create a single histogram. The histogram can then be averaged over longer timescales. The resulting histogram can be used by other output commands, and can also be written to a file. The fix ave/histo/weight command has identical syntax to fix ave/histo, except that exactly two values must be specified. See details below.

The group specified with this command is ignored for global and local input values. For per-atom input values, only atoms in the group contribute to the histogram. Note that regardless of the specified group, specified values may represent calculations performed by computes and fixes which store their own “group” definition.

A histogram is simply a count of the number of values that fall within a histogram bin. Nbins are defined, with even spacing between lo and hi. Values that fall outside the lo/hi bounds can be treated in different ways; see the discussion of the beyond keyword below.

Each input value can be an atom attribute (position, velocity, force component) or can be the result of a compute or fix or the evaluation of an equal-style or atom-style variable. The set of input values can be either all global, all per-atom, or all local quantities. Inputs of different kinds (e.g. global and per-atom) cannot be mixed. Atom attributes are per-atom vector values. See the doc page for individual “compute” and “fix” commands to see what kinds of quantities they generate. See the optional kind keyword below for how to force the fix ave/histo command to disambiguate if necessary.

Note that the output of this command is a single histogram for all input values combined together, not one histogram per input value. See below for details on the format of the output of this fix.

The input values must either be all scalars or all vectors (or arrays), depending on the setting of the mode keyword.

If mode = scalar, then the input values must be scalars, or vectors with a bracketed term appended, indicating the Ith value of the vector is used.

If mode = vector, then the input values must be vectors, or arrays with a bracketed term appended, indicating the Ith column of the array is used.

Note that for values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the size of the vector (for mode = scalar) or the number of columns in the array (for mode = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).
Using a wildcard is the same as if the individual elements of the vector or columns of the array had been listed one by one. E.g. these 2 fix ave/histo commands are equivalent, since the **compute com/chunk** command creates a global array with 3 columns:

```plaintext
compute myCOM all com/chunk
fix 1 all ave/histo 100 1 100 c_myCOM[*] file tmpl.com mode vector
```

If the fix ave/histo/weight command is used, exactly two values must be specified. If the values are vectors, they must be the same length. The first value (a scalar or vector) is what is histogrammed into bins, in the same manner the fix ave/histo command operates. The second value (a scalar or vector) is used as a “weight”. This means that instead of each value tallying a “1” to its bin, the corresponding weight is tallied. E.g. The Nth entry (weight) in the second vector is tallied to the bin corresponding to the Nth entry in the first vector.

The **Nevery**, **Nrepeat**, and **Nfreq** arguments specify on what timesteps the input values will be used in order to contribute to the histogram. The final histogram is generated on timesteps that are multiple of **Nfreq**. It is averaged over **Nrepeat** histograms, computed in the preceding portion of the simulation every **Nevery** timesteps. **Nfreq** must be a multiple of **Nevery** and **Nevery** must be non-zero even if **Nrepeat** is 1. Also, the timesteps contributing to the histogram value cannot overlap, i.e. **Nrepeat*****Nevery** can not exceed **Nfreq**.

For example, if **Nevery**=2, **Nrepeat**=6, and **Nfreq**=100, then input values on timesteps 90,92,94,96,98,100 will be used to compute the final histogram on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If **Nrepeat**=1 and **Nfreq** = 100, then no time averaging of the histogram is done; a histogram is simply generated on timesteps 100,200,etc.

The atom attribute values (x,y,z,vx,vy,vz,fx, fy,fz) are self-explanatory. Note that other atom attributes can be used as inputs to this fix by using the **compute property/atom** command and then specifying an input value from that compute.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. If **mode** = scalar, then if no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the Ith element of the global vector calculated by the compute is used. If **mode** = vector, then if no bracketed term is appended, the global or per-atom or local vector calculated by the compute is used. If a bracketed term is appended, the Ith column of the global or per-atom or local array calculated by the compute is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a **compute reduce** command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by fix ave/histo. Or it can be a compute defined not in your input script, but by thermodynamic **output** or other fixes such as fix nvt or fix temp/rescale. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and **add them to LAMMPS**.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. If **mode** = scalar, then if no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used. If **mode** = vector, then if no bracketed term is appended, the global or per-atom or local vector calculated by the fix is used. If a bracketed term is appended, the Ith column of the global or per-atom or local array calculated by the fix is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that some fixes only produce their values on certain timesteps, which must be compatible with **Nevery**, else an error will result. Users can also write code for their own fix styles and **add them to LAMMPS**.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. If **mode** = scalar, then only equal-style or vector-style variables can be used, which both produce global values. In this mode, a vector-style variable requires a bracketed term to specify the Ith element of the vector calculated by the variable. If
mode = vector, then only vector-style or atom-style variables can be used, which produce a global or per-atom vector respectively. The vector-style variable must be used without a bracketed term. See the variable command for details.

Note that variables of style equal, vector, and atom define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to histogram.

Additional optional keywords also affect the operation of this fix.

If the mode keyword is set to scalar, then all input values must be global scalars, or elements of global vectors. If the mode keyword is set to vector, then all input values must be global or per-atom or local vectors, or columns of global or per-atom or local arrays.

The kind keyword only needs to be set if a compute or fix produces more than one kind of output (global, per-atom, local). If this is not the case, then LAMMPS will determine what kind of input is provided and whether all the input arguments are consistent. If a compute or fix produces more than one kind of output, the kind keyword should be used to specify which output will be used. The remaining input arguments must still be consistent.

The beyond keyword determines how input values that fall outside the lo to hi bounds are treated. Values such that lo <= value <= hi are assigned to one bin. Values on a bin boundary are assigned to the lower of the 2 bins. If beyond is set to ignore then values < lo and values > hi are ignored, i.e. they are not binned. If beyond is set to end then values < lo are counted in the first bin and values > hi are counted in the last bin. If beyond is set to extend then two extra bins are created, so that there are Nbins+2 total bins. Values < lo are counted in the first bin and values > hi are counted in the last bin (Nbins+2). Values between lo and hi (inclusive) are counted in bins 2 through Nbins+1. The “coordinate” stored and printed for these two extra bins is lo and hi.

The ave keyword determines how the histogram produced every Nfreq steps are averaged with histograms produced on previous steps that were multiples of Nfreq, before they are accessed by another output command or written to a file.

If the ave setting is one, then the histograms produced on timesteps that are multiples of Nfreq are independent of each other; they are output as-is without further averaging.

If the ave setting is running, then the histograms produced on timesteps that are multiples of Nfreq are summed and averaged in a cumulative sense before being output. Each bin value in the histogram is thus the average of the bin value produced on that timestep with all preceding values for the same bin. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the unfix command, or by re-defining the fix by re-specifying it.

If the ave setting is window, then the histograms produced on timesteps that are multiples of Nfreq are summed within a moving “window” of time, so that the last M histograms are used to produce the output. E.g. if M = 3 and Nfreq = 1000, then the output on step 10000 will be the combined histogram of the individual histograms on steps 8000,9000,10000. Outputs on early steps will be sums over less than M histograms if they are not available.

The start keyword specifies what timestep histogramming will begin on. The default is step 0. Often input values can be 0.0 at time 0, so setting start to a larger value can avoid including a 0.0 in a running or windowed histogram.

The file keyword allows a filename to be specified. Every Nfreq steps, one histogram is written to the file. This includes a leading line that contains the timestep, number of bins, the total count of values contributing to the histogram, the count of values that were not histogrammed (see the beyond keyword), the minimum value encountered, and the maximum value encountered. The min/max values include values that were not histogrammed. Following the leading line, one line per bin is written into the file. Each line contains the bin #, the coordinate for the center of the bin (between lo and hi), the count of values in the bin, and the normalized count. The normalized count is the bin count divided by the total count (not including values not histogrammed), so that the normalized values sum to 1.0 across all bins.

The overwrite keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the ave running setting.
The *title1* and *title2* and *title3* keywords allow specification of the strings that will be printed as the first 3 lines of the output file, assuming the *file* keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:

```
# Histogram for fix ID
# TimeStep Number-of-bins Total-counts Missing-counts Min-value Max-value
# Bin Coord Count Count/Total
```

In the first line, ID is replaced with the fix-ID. The second line describes the six values that are printed at the first of each section of output. The third describes the 4 values printed for each bin in the histogram.

### 18.14.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix.

This fix produces a global vector and global array which can be accessed by various *output commands*. The values can only be accessed on timesteps that are multiples of *Nfreq* since that is when a histogram is generated. The global vector has 4 values:

- 1 = total counts in the histogram
- 2 = values that were not histogrammed (see *beyond* keyword)
- 3 = min value of all input values, including ones not histogrammed
- 4 = max value of all input values, including ones not histogrammed

The global array has # of rows = *Nbins* and # of columns = 3. The first column has the bin coordinate, the second column has the count of values in that histogram bin, and the third column has the bin count divided by the total count (not including missing counts), so that the values in the third column sum to 1.0.

The vector and array values calculated by this fix are all treated as intensive. If this is not the case, e.g. due to histogramming per-atom input values, then you will need to account for that when interpreting the values produced by this fix.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 18.14.5 Restrictions

none

### 18.14.6 Related commands

*compute, fix ave/atom, fix ave/chunk, fix ave/time, variable, fix ave/correlate*
18.14.7 Default

none

The option defaults are mode = scalar, kind = figured out from input arguments, ave = one, start = 0, no file output, beyond = ignore, and title 1,2,3 = strings as described above.

18.15 fix ave/time command

18.15.1 Syntax

```
fix ID group-ID ave/time Nevery Nrepeat Nfreq value1 value2 ... keyword args ...
```

- ID, group-ID are documented in `fix` command
- ave/time = style name of this fix command
- Nevery = use input values every this many timesteps
- Nrepeat = # of times to use input values for calculating averages
- Nfreq = calculate averages every this many timesteps
- one or more input values can be listed
- value = c_ID, c_ID[I], f_ID, f_ID[I], v_name
  - c_ID = global scalar or vector calculated by a compute with ID
  - c_ID[I] = Ith component of global vector or Ith column of global array calculated by a compute with ID
  - f_ID = global scalar or vector calculated by a fix with ID
  - f_ID[I] = Ith component of global vector or Ith column of global array calculated by a fix with ID
  - v_name = value(s) calculated by an equal-style or vector-style variable with name
  - v_name[I] = value calculated by a vector-style variable with name

- zero or more keyword/arg pairs may be appended
- keyword = mode or file or ave or start or off or overwrite or title1 or title2 or title3
  - mode arg = scalar or vector
    - scalar = all input values are global scalars
    - vector = all input values are global vectors or global arrays
  - ave args = one or running or window M
    - one = output a new average value every Nfreq steps
    - running = output cumulative average of all previous Nfreq steps
    - window M = output average of M most recent Nfreq steps
  - start args = Nstart
    - Nstart = start averaging on this timestep
  - off arg = M = do not average this value
    - M = value # from 1 to Nvalues
  - file arg = filename
    - filename = name of file to output time averages to
  - overwrite arg = none = overwrite output file with only latest output
  - format arg = string
    - string = C-style format string
  - title1 arg = string
18.15.2 Examples

```plaintext
fix 1 all ave/time 100 5 1000 c_myTemp c_thermo_temp file temp.profile
fix 1 all ave/time 100 5 1000 c_thermo_press[2] ave window 20 &
    title1 "My output values"
fix 1 all ave/time 100 5 1000 c_thermo_press[*]
fix 1 all ave/time 1 100 1000 f_indent f_indent[1] file temp.indent off 1
```

18.15.3 Description

Use one or more global values as inputs every few timesteps, and average them over longer timescales. The resulting averages can be used by other output commands such as `thermo_style custom`, and can also be written to a file. Note that if no time averaging is done, this command can be used as a convenient way to simply output one or more global values to a file.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a compute or fix or the evaluation of an equal-style or vector-style variable. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity. If you wish to spatial- or time-average or histogram per-atom quantities from a compute, fix, or variable, then see the `fix ave/chunk`, `fix ave/atom`, or `fix ave/histo` commands. If you wish to sum a per-atom quantity into a single global quantity, see the `compute reduce` command.

Computes that produce global quantities are those which do not have the word `atom` in their style name. Only a few fixes produce global quantities. See the doc pages for individual fixes for info on which ones produce such values. Variables of style `equal` and `vector` are the only ones that can be used with this fix. Variables of style `atom` cannot be used, since they produce per-atom values.

The input values must either be all scalars or all vectors depending on the setting of the `mode` keyword. In both cases, the averaging is performed independently on each input value. I.e. each input scalar is averaged independently or each element of each input vector is averaged independently.

If `mode = scalar`, then the input values must be scalars, or vectors with a bracketed term appended, indicating the Ith value of the vector is used.

If `mode = vector`, then the input values must be vectors, or arrays with a bracketed term appended, indicating the Ith column of the array is used. All vectors must be the same length, which is the length of the vector or number of rows in the array.

Note that for values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If \( N = \) the size of the vector (for `mode = scalar`) or the number of columns in the array (for `mode = vector`), then an asterisk with no numeric values means all indices from 1 to \( N \). A leading asterisk means all indices from 1 to \( n \) (inclusive). A trailing asterisk means all indices from \( n \) to \( N \) (inclusive). A middle asterisk means all indices from \( m \) to \( n \) (inclusive).

Using a wildcard is the same as if the individual elements of the vector or columns of the array had been listed one by one. E.g. these 2 fix ave/time commands are equivalent, since the `compute rdf` command creates, in this case, a global array with 3 columns, each of length 50:
The \texttt{Nevery}, \texttt{Nrepeat}, and \texttt{Nfreq} arguments specify on what timesteps the input values will be used in order to contribute to the average. The final averaged quantities are generated on timesteps that are a multiple of \texttt{Nfreq}. The average is over \texttt{Nrepeat} quantities, computed in the preceding portion of the simulation every \texttt{Nevery} timesteps. \texttt{Nfreq} must be a multiple of \texttt{Nevery} and \texttt{Nevery} must be non-zero even if \texttt{Nrepeat} is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. \texttt{Nrepeat*Nevery} can not exceed \texttt{Nfreq}.

For example, if \texttt{Nevery}=2, \texttt{Nrepeat}=6, and \texttt{Nfreq}=100, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If \texttt{Nrepeat}=1 and \texttt{Nfreq} = 100, then no time averaging is done; values are simply generated on timesteps 100,200, etc.

If a value begins with “c\_”, a compute ID must follow which has been previously defined in the input script. If \texttt{mode} = scalar, then if no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the Ith element of the global vector calculated by the compute is used. If \texttt{mode} = vector, then if no bracketed term is appended, the global vector calculated by the compute is used. If a bracketed term is appended, the Ith column of the global array calculated by the compute is used. See the discussion above for how \texttt{I} can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a \texttt{compute reduce} command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by fix ave/time. Or it can be a compute defined not in your input script, but by \textit{thermodynamic output} or other fixes such as \texttt{fix nvt} or \texttt{fix temp/rescale}. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and \textit{add them to LAMMPS}.

If a value begins with “f\_”, a fix ID must follow which has been previously defined in the input script. If \texttt{mode} = scalar, then if no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used. If \texttt{mode} = vector, then if no bracketed term is appended, the global vector calculated by the fix is used. If a bracketed term is appended, the Ith column of the global array calculated by the fix is used. See the discussion above for how \texttt{I} can be specified with a wildcard asterisk to effectively specify multiple values.

Note that some fixes only produce their values on certain timesteps, which must be compatible with \texttt{Nevery}, else an error will result. Users can also write code for their own fix styles and \textit{add them to LAMMPS}.

If a value begins with “v\_”, a variable name must follow which has been previously defined in the input script. If \texttt{mode} = scalar, then only equal-style or vector-style variables can be used, which both produce global values. In this mode, a vector-style variable requires a bracketed term to specify the Ith element of the vector calculated by the variable. If \texttt{mode} = vector, then only a vector-style variable can be used, without a bracketed term. See the \texttt{variable} command for details.

Note that variables of style \textit{equal} and \textit{vector} define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to time average.

Additional optional keywords also affect the operation of this fix.

If the \texttt{mode} keyword is set to \textit{scalar}, then all input values must be global scalars, or elements of global vectors. If the \texttt{mode} keyword is set to \textit{vector}, then all input values must be global vectors, or columns of global arrays. They can also be global arrays, which are converted into a series of global vectors (one per column), as explained above.
The `ave` keyword determines how the values produced every `Nfreq` steps are averaged with values produced on previous steps that were multiples of `Nfreq`, before they are accessed by another output command or written to a file.

If the `ave` setting is `one`, then the values produced on timesteps that are multiples of `Nfreq` are independent of each other; they are output as-is without further averaging.

If the `ave` setting is `running`, then the values produced on timesteps that are multiples of `Nfreq` are summed and averaged in a cumulative sense before being output. Each output value is thus the average of the value produced on that timestep with all preceding values. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the `unfix` command, or by re-defining the fix by re-specifying it.

If the `ave` setting is `window`, then the values produced on timesteps that are multiples of `Nfreq` are summed and averaged within a moving “window” of time, so that the last `M` values are used to produce the output. E.g. if `M = 3` and `Nfreq = 1000`, then the output on step 10000 will be the average of the individual values on steps 8000,9000,10000. Outputs on early steps will average over less than `M` values if they are not available.

The `start` keyword specifies what timestep averaging will begin on. The default is step 0. Often input values can be 0.0 at time 0, so setting `start` to a larger value can avoid including a 0.0 in a running or windowed average.

The `off` keyword can be used to flag any of the input values. If a value is flagged, it will not be time averaged. Instead the most recent input value will always be stored and output. This is useful if one of more of the inputs produced by a compute or fix or variable are effectively constant or are simply current values. E.g. they are being written to a file with other time-averaged values for purposes of creating well-formatted output.

The `file` keyword allows a filename to be specified. Every `Nfreq` steps, one quantity or vector of quantities is written to the file for each input value specified in the fix `ave/time` command. For `mode = scalar`, this means a single line is written each time output is performed. Thus the file ends up to be a series of lines, i.e. one column of numbers for each input value. For `mode = vector`, an array of numbers is written each time output is performed. The number of rows is the length of the input vectors, and the number of columns is the number of values. Thus the file ends up to be a series of these array sections.

The `overwrite` keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the `ave running` setting.

The `format` keyword sets the numeric format of each value when it is printed to a file via the `file` keyword. Note that all values are floating point quantities. The default format is `%g`. You can specify a higher precision if desired, e.g. `%20.16g`.

The `title1` and `title2` and `title3` keywords allow specification of the strings that will be printed as the first 2 or 3 lines of the output file, assuming the `file` keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows for `mode = scalar`:

```plaintext
# Time-averaged data for fix ID
# TimeStep value1 value2 ...
```

In the first line, ID is replaced with the fix-ID. In the second line the values are replaced with the appropriate fields from the fix `ave/time` command. There is no third line in the header of the file, so the `title3` setting is ignored when `mode = scalar`.

By default, these header lines are as follows for `mode = vector`:

```plaintext
# Time-averaged data for fix ID
# TimeStep Number-of-rows
# Row value1 value2 ...
```

In the first line, ID is replaced with the fix-ID. The second line describes the two values that are printed at the first of each section of output. In the third line the values are replaced with the appropriate fields from the fix `ave/time` command.
18.15.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix produces a global scalar or global vector or global array which can be accessed by various output commands. The values can only be accessible on timesteps that are multiples of Nfreq since that is when averaging is performed.

A scalar is produced if only a single input value is averaged and mode = scalar. A vector is produced if multiple input values are averaged for mode = scalar, or a single input value for mode = vector. In the first case, the length of the vector is the number of inputs. In the second case, the length of the vector is the same as the length of the input vector. An array is produced if multiple input values are averaged and mode = vector. The global array has # of rows = length of the input vectors and # of columns = number of inputs.

If the fix produces a scalar or vector, then the scalar and each element of the vector can be either “intensive” or “extensive”, depending on whether the values contributing to the scalar or vector element are “intensive” or “extensive”. If the fix produces an array, then all elements in the array must be the same, either “intensive” or “extensive”. If a compute or fix provides the value being time averaged, then the compute or fix determines whether the value is intensive or extensive; see the doc page for that compute or fix for further info. Values produced by a variable are treated as intensive.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.15.5 Restrictions

none

18.15.6 Related commands

compute, fix ave/atom, fix ave/chunk, fix ave/histo, variable, fix ave/correlate,

18.15.7 Default

The option defaults are mode = scalar, ave = one, start = 0, no file output, format = %g, title 1,2,3 = strings as described above, and no off settings for any input values.

18.16 fix aveforce command

18.16.1 Syntax

fix ID group-ID aveforce fx fy fz keyword value ...

- ID, group-ID are documented in fix command
- aveforce = style name of this fix command
- fx,fy,fz = force component values (force units)
any of fx, fy, fz can be a variable (see below)

- zero or more keyword/value pairs may be appended to args
- keyword = region
  region value = region-ID
  region-ID = ID of region atoms must be in to have added force

18.16.2 Examples

```latex
\begin{verbatim}
fix pressdown topwall aveforce 0.0 -1.0 0.0
fix 2 bottomwall aveforce NULL -1.0 0.0 region top
fix 2 bottomwall aveforce NULL -1.0 v_oscillate region top
\end{verbatim}
```

18.16.3 Description

Apply an additional external force to a group of atoms in such a way that every atom experiences the same force. This is useful for pushing on wall or boundary atoms so that the structure of the wall does not change over time.

The existing force is averaged for the group of atoms, component by component. The actual force on each atom is then set to the average value plus the component specified in this command. This means each atom in the group receives the same force.

Any of the fx, fy, fz values can be specified as NULL which means the force in that dimension is not changed. Note that this is not the same as specifying a 0.0 value, since that sets all forces to the same average value without adding in any additional force.

Any of the 3 quantities defining the force components can be specified as an equal-style variable, namely fx, fy, fz. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the average force.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent average force.

If the region keyword is used, the atom must also be in the specified geometric region in order to have force added to it.

---

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
18.16.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global 3-vector of forces, which can be accessed by various output commands. This is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

2 all balance 1000 1.1 rcb
```

18.17.3 Description

This command adjusts the size and shape of processor sub-domains within the simulation box, to attempt to balance the number of particles and thus the computational cost (load) evenly across processors. The load balancing is “dynamic” in the sense that re-balancing is performed periodically during the simulation. To perform “static” balancing, before or between runs, see the `balance` command.

Load-balancing is typically most useful if the particles in the simulation box have a spatially-varying density distribution or where the computational cost varies significantly between different atoms. E.g. a model of a vapor/liquid interface, or a solid with an irregular-shaped geometry containing void regions, or hybrid pair style simulations which combine pair styles with different computational cost. In these cases, the LAMMPS default of dividing the simulation box volume into a regular-spaced grid of 3d bricks, with one equal-volume sub-domain per processor, may assign numbers of particles per processor in a way that the computational effort varies significantly. This can lead to poor performance when the simulation is run in parallel.

The balancing can be performed with or without per-particle weighting. With no weighting, the balancing attempts to assign an equal number of particles to each processor. With weighting, the balancing attempts to assign an equal aggregate computational weight to each processor, which typically induces a different number of atoms assigned to each processor.

Note: The weighting options listed above are documented with the `balance` command in this section of the `balance command` doc page. That section describes the various weighting options and gives a few examples of how they can...
be used. The weighting options are the same for both the fix balance and \textit{balance} commands.

Note that the \textit{processors} command allows some control over how the box volume is split across processors. Specifically, for a \( P_x \) by \( P_y \) by \( P_z \) grid of processors, it allows choice of \( P_x, P_y, \) and \( P_z \), subject to the constraint that \( P_x \ast P_y \ast P_z = P \), the total number of processors. This is sufficient to achieve good load-balance for some problems on some processor counts. However, all the processor sub-domains will still have the same shape and same volume.

On a particular timestep, a load-balancing operation is only performed if the current “imbalance factor” in particles owned by each processor exceeds the specified \textit{thresh} parameter. The imbalance factor is defined as the maximum number of particles (or weight) owned by any processor, divided by the average number of particles (or weight) per processor. Thus an imbalance factor of 1.0 is perfect balance.

As an example, for 10000 particles running on 10 processors, if the most heavily loaded processor has 1200 particles, then the factor is 1.2, meaning there is a 20\% imbalance. Note that re-balances can be forced even if the current balance is perfect (1.0) by specifying a \textit{thresh} < 1.0.

\textbf{Note:} This command attempts to minimize the imbalance factor, as defined above. But depending on the method a perfect balance (1.0) may not be achieved. For example, “grid” methods (defined below) that create a logical 3d grid cannot achieve perfect balance for many irregular distributions of particles. Likewise, if a portion of the system is a perfect lattice, e.g. the initial system is generated by the \textit{create_atoms} command, then “grid” methods may be unable to achieve exact balance. This is because entire lattice planes will be owned or not owned by a single processor.

\textbf{Note:} The imbalance factor is also an estimate of the maximum speed-up you can hope to achieve by running a perfectly balanced simulation versus an imbalanced one. In the example above, the 10000 particle simulation could run up to 20\% faster if it were perfectly balanced, versus when imbalanced. However, computational cost is not strictly proportional to particle count, and changing the relative size and shape of processor sub-domains may lead to additional computational and communication overheads, e.g. in the PPPM solver used via the \textit{kspace_style} command. Thus you should benchmark the run times of a simulation before and after balancing.

The method used to perform a load balance is specified by one of the listed styles, which are described in detail below. There are 2 kinds of styles.

The \textit{shift} style is a “grid” method which produces a logical 3d grid of processors. It operates by changing the cutting planes (or lines) between processors in 3d (or 2d), to adjust the volume (area in 2d) assigned to each processor, as in the following 2d diagram where processor sub-domains are shown and atoms are colored by the processor that owns them.

The leftmost diagram is the default partitioning of the simulation box across processors (one sub-box for each of 16 processors); the middle diagram is after a “grid” method has been applied. The \textit{rcb} style is a “tiling” method which
LAMMPS Documentation
does not produce a logical 3d grid of processors. Rather it tiles the simulation domain with rectangular sub-boxes of varying size and shape in an irregular fashion so as to have equal numbers of particles (or weight) in each sub-box, as in the rightmost diagram above.

The “grid” methods can be used with either of the comm_style command options, brick or tiled. The “tiling” methods can only be used with comm_style tiled.

When a “grid” method is specified, the current domain partitioning can be either a logical 3d grid or a tiled partitioning. In the former case, the current logical 3d grid is used as a starting point and changes are made to improve the imbalance factor. In the latter case, the tiled partitioning is discarded and a logical 3d grid is created with uniform spacing in all dimensions. This is the starting point for the balancing operation.

When a “tiling” method is specified, the current domain partitioning (“grid” or “tiled”) is ignored, and a new partitioning is computed from scratch.

The group-ID is ignored. However the impact of balancing on different groups of atoms can be affected by using the group weight style as described below.

The Nfreq setting determines how often a re-balance is performed. If Nfreq > 0, then re-balancing will occur every Nfreq steps. Each time a re-balance occurs, a reneighboring is triggered, so Nfreq should not be too small. If Nfreq = 0, then re-balancing will be done every time reneighboring normally occurs, as determined by the the neighbor and neigh_modify command settings.

On re-balance steps, re-balancing will only be attempted if the current imbalance factor, as defined above, exceeds the thresh setting.

The shift style invokes a “grid” method for balancing, as described above. It changes the positions of cutting planes between processors in an iterative fashion, seeking to reduce the imbalance factor.

The dimstr argument is a string of characters, each of which must be an “x” or “y” or “z”. Each character can appear zero or one time, since there is no advantage to balancing on a dimension more than once. You should normally only list dimensions where you expect there to be a density variation in the particles.

Balancing proceeds by adjusting the cutting planes in each of the dimensions listed in dimstr, one dimension at a time. For a single dimension, the balancing operation (described below) is iterated on up to Niter times. After each dimension finishes, the imbalance factor is re-computed, and the balancing operation halts if the stopthresh criterion is met.

A re-balance operation in a single dimension is performed using a density-dependent recursive multisectoning algorithm, where the position of each cutting plane (line in 2d) in the dimension is adjusted independently. This is similar to a recursive bisectioning for a single value, except that the bounds used for each bisectioning take advantage of information from neighboring cuts if possible, as well as counts of particles at the bounds on either side of each cuts, which themselves were cuts in previous iterations. The latter is used to infer a density of particles near each of the current cuts. At each iteration, the count of particles on either side of each plane is tallied. If the counts do not match the target value for the plane, the position of the cut is adjusted based on the local density. The low and high bounds are adjusted on each iteration, using new count information, so that they become closer together over time. Thus as the recursion progresses, the count of particles on either side of the plane gets closer to the target value.

The density-dependent part of this algorithm is often an advantage when you re-balance a system that is already nearly balanced. It typically converges more quickly than the geometric bisectioning algorithm used by the balance command. However, if can be a disadvantage if you attempt to re-balance a system that is far from balanced, and converge more slowly. In this case you probably want to use the balance command before starting a run, so that you begin the run with a balanced system.

Once the re-balancing is complete and final processor sub-domains assigned, particles migrate to their new owning processor as part of the normal reneighboring procedure.

18.17. fix balance command 963
Note: At each re-balance operation, the bisectioning for each cutting plane (line in 2d) typically starts with low and high bounds separated by the extent of a processor’s sub-domain in one dimension. The size of this bracketing region shrinks based on the local density, as described above, which should typically be 1/2 or more every iteration. Thus if \( N_{iter} \) is specified as 10, the cutting plane will typically be positioned to better than 1 part in 1000 accuracy (relative to the perfect target position). For \( N_{iter} = 20 \), it will be accurate to better than 1 part in a million. Thus there is no need to set \( N_{iter} \) to a large value. This is especially true if you are re-balancing often enough that each time you expect only an incremental adjustment in the cutting planes is necessary. LAMMPS will check if the threshold accuracy is reached (in a dimension) is less iterations than \( N_{iter} \) and exit early.

The \texttt{rcb} style invokes a “tiled” method for balancing, as described above. It performs a recursive coordinate bisectioning (RCB) of the simulation domain. The basic idea is as follows.

The simulation domain is cut into 2 boxes by an axis-aligned cut in the longest dimension, leaving one new box on either side of the cut. All the processors are also partitioned into 2 groups, half assigned to the box on the lower side of the cut, and half to the box on the upper side. (If the processor count is odd, one side gets an extra processor.) The cut is positioned so that the number of atoms in the lower box is exactly the number that the processors assigned to that box should own for load balance to be perfect. This also makes load balance for the upper box perfect. The positioning is done iteratively, by a bisectioning method. Note that counting atoms on either side of the cut requires communication between all processors at each iteration.

That is the procedure for the first cut. Subsequent cuts are made recursively, in exactly the same manner. The subset of processors assigned to each box make a new cut in the longest dimension of that box, splitting the box, the subset of processors, and the atoms in the box in two. The recursion continues until every processor is assigned a sub-box of the entire simulation domain, and owns the atoms in that sub-box.

The \texttt{out} keyword writes text to the specified \texttt{filename} with the results of each re-balancing operation. The file contains the bounds of the sub-domain for each processor after the balancing operation completes. The format of the file is compatible with the \texttt{Pizza.py mdump} tool which has support for manipulating and visualizing mesh files. An example is shown here for a balancing by 4 processors for a 2d problem:

```
ITEM: TIMESTEP
0
ITEM: NUMBER OF NODES
16
ITEM: BOX BOUNDS
0 10
0 10
0 10
ITEM: NODES
1 1 0 0 0
2 1 5 0 0
3 1 5 5 0
4 1 0 5 0
5 1 5 0 0
6 1 10 0 0
7 1 10 5 0
8 1 5 5 0
9 1 0 5 0
10 1 5 5 0
11 1 5 10 0
12 1 10 5 0
13 1 5 5 0
```
The coordinates of all the vertices are listed in the NODES section, 5 per processor. Note that the 4 sub-domains share vertices, so there will be duplicate nodes in the list.

The “SQUARES” section lists the node IDs of the 4 vertices in a rectangle for each processor (1 to 4).

For a 3d problem, the syntax is similar with 8 vertices listed for each processor, instead of 4, and “SQUARES” replaced by “CUBES”.

18.17.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes a global scalar which is the imbalance factor after the most recent re-balance and a global vector of length 3 with additional information about the most recent re-balancing. The 3 values in the vector are as follows:

- 1 = max # of particles per processor
- 2 = total # iterations performed in last re-balance
- 3 = imbalance factor right before the last re-balance was performed

As explained above, the imbalance factor is the ratio of the maximum number of particles (or total weight) on any processor to the average number of particles (or total weight) per processor.

These quantities can be accessed by various output commands. The scalar and vector values calculated by this fix are “intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.17.5 Restrictions

For 2d simulations, the $z$ style cannot be used. Nor can a “z” appear in dimstr for the shift style.

Balancing through recursive bisectioning (rcb style) requires comm_style tiled
18.17.6 Related commands

`group`, `processors`, `balance`, `comm_style`

`none`

18.18 fix bocs command

18.18.1 Syntax

```
fix  ID group-ID bocs keyword values ...
```

`keyword = temp or cgiso or analytic or linear_spline or cubic_spline`

- `temp` values = `Tstart Tstop Tdamp`
- `cgiso` values = `Pstart Pstop Pdamp`
- `basis set`
  - `analytic` values = `V_avg N_particles N_coeff Coeff_1 Coeff_2 ... Coeff_N`
  - `linear_spline` values = `input_filename`
  - `cubic_spline` values = `input_filename`

18.18.2 Examples

```
fix 1 all bocs temp 300.0 300.0 100.0 cgiso 0.986 0.986 1000.0 analytic 66476.015 968 ..
       2 245030.10 8962.20
fix 1 all bocs temp 300.0 300.0 100.0 cgiso 0.986 0.986 1000.0 cubic_spline input_Fv.dat
thermo_modify press 1_press
```

18.18.3 Description

These commands incorporate a pressure correction as described by Dunn and Noid in (Dunn1) to the standard MTTK barostat by Martyna et. al. in (Martyna). The first half of the command mimics a standard fix npt command:

```
fix 1 all bocs temp Tstart Tstop Tcoupl cgiso Pstart Pstop Pdamp
```

The two differences are replacing `npt` with `bocs`, and replacing `isolanisoletc` with `cgiso`. The rest of the command details what form you would like to use for the pressure correction equation. The choices are: `analytic`, `linear_spline`, or `cubic_spline`.

With either spline method, the only argument that needs to follow it is the name of a file that contains the desired pressure correction as a function of volume. The file must be formatted so each line has:

```
Volume_i, PressureCorrection_i
```
Note both the COMMA and the SPACE separating the volume’s value and its corresponding pressure correction. The volumes in the file must be uniformly spaced. Both the volumes and the pressure corrections should be provided in the proper units, e.g. if you are using units real, the volumes should all be in cubic angstroms, and the pressure corrections should all be in atmospheres. Furthermore, the table should start/end at a volume considerably smaller/larger than you expect your system to sample during the simulation. If the system ever reaches a volume outside of the range provided, the simulation will stop.

With the analytic option, the arguments are as follows:

```
... analytic V_avg N_particles N_coeff Coeff_1 Coeff_2 ... Coeff_N
```

Note that $V_{avg}$ and $Coeff_i$ should all be in the proper units, e.g. if you are using units real, $V_{avg}$ should be in cubic angstroms, and the coefficients should all be in atmospheres * cubic angstroms.

### 18.18.4 Restrictions

As this is computing a (modified) pressure, group-ID should be all.

The pressure correction has only been tested for use with an isotropic pressure coupling in 3 dimensions.

By default, LAMMPS will still report the normal value for the pressure if the pressure is printed via a thermo command, or if the pressures are written to a file every so often. In order to have LAMMPS report the modified pressure, you must include the thermo_modify command given in the examples. For the last argument in the command, you should put XXXX_press, where XXXX is the ID given to the fix bocs command (in the example, the ID of the fix bocs command is 1).

This fix is part of the USER-BOCS package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

### 18.18.5 Further information

For more details about the pressure correction and the entire BOCS software package, visit the BOCS package on GitHub and read the release paper by Dunn et. al. (Dunn2).

### 18.19 fix bond/break command

#### 18.19.1 Syntax

```
fix ID group-ID bond/break Nevery bondtype Rmax keyword values ...
```

- ID, group-ID are documented in fix command
- bond/break = style name of this fix command
- Nevery = attempt bond breaking every this many steps
- bondtype = type of bonds to break
• Rmax = bond longer than Rmax can break (distance units)
• zero or more keyword/value pairs may be appended to args
• keyword = prob
  prob values = fraction seed
  fraction = break a bond with this probability if otherwise eligible
  seed = random number seed (positive integer)

18.19.2 Examples

```latex
\begin{verbatim}
fix 5 all bond/break 10 2 1.2
fix 5 polymer bond/break 1 1 2.0 prob 0.5 49829
\end{verbatim}
```

18.19.3 Description

Break bonds between pairs of atoms as a simulation runs according to specified criteria. This can be used to model the dissolution of a polymer network due to stretching of the simulation box or other deformations. In this context, a bond means an interaction between a pair of atoms computed by the `bond_style` command. Once the bond is broken it will be permanently deleted, as will all angle, dihedral, and improper interactions that bond is part of.

This is different than a pairwise bond-order potential such as Tersoff or AIREBO which infers bonds and many-body interactions based on the current geometry of a small cluster of atoms and effectively creates and destroys bonds and higher-order many-body interactions from timestep to timestep as atoms move.

A check for possible bond breakage is performed every `Nevery` timesteps. If two bonded atoms I,J are further than a distance `Rmax` of each other, if the bond is of type `bondtype`, and if both I and J are in the specified fix group, then I,J is labeled as a “possible” bond to break.

If several bonds involving an atom are stretched, it may have multiple possible bonds to break. Every atom checks its list of possible bonds to break and labels the longest such bond as its “sole” bond to break. After this is done, if atom I is bonded to atom J in its sole bond, and atom J is bonded to atom I in its sole bond, then the I,J bond is “eligible” to be broken.

Note that these rules mean an atom will only be part of at most one broken bond on a given timestep. It also means that if atom I chooses atom J as its sole partner, but atom J chooses atom K as its sole partner (due to $R_{jk} > R_{ij}$), then this means atom I will not be part of a broken bond on this timestep, even if it has other possible bond partners.

The `prob` keyword can effect whether an eligible bond is actually broken. The `fraction` setting must be a value between 0.0 and 1.0. A uniform random number between 0.0 and 1.0 is generated and the eligible bond is only broken if the random number < fraction.

When a bond is broken, data structures within LAMMPS that store bond topology are updated to reflect the breakage. Likewise, if the bond is part of a 3-body (angle) or 4-body (dihedral, improper) interaction, that interaction is removed as well. These changes typically affect pairwise interactions between atoms that used to be part of bonds, angles, etc.

**Note:** One data structure that is not updated when a bond breaks are the molecule IDs stored by each atom. Even though one molecule becomes two molecules due to the broken bond, all atoms in both new molecules retain their original molecule IDs.

Computationally, each timestep this fix operates, it loops over all the bonds in the system and computes distances between pairs of bonded atoms. It also communicates between neighboring processors to coordinate which bonds are broken. Moreover, if any bonds are broken, neighbor lists must be immediately updated on the same timestep. This is to insure that any pairwise interactions that should be turned “on” due to a bond breaking, because they are
no longer excluded by the presence of the bond and the settings of the special_bonds command, will be immediately recognized. All of these operations increase the cost of a timestep. Thus you should be cautious about invoking this fix too frequently.

You can dump out snapshots of the current bond topology via the dump local command.

Note: Breaking a bond typically alters the energy of a system. You should be careful not to choose bond breaking criteria that induce a dramatic change in energy. For example, if you define a very stiff harmonic bond and break it when 2 atoms are separated by a distance far from the equilibrium bond length, then the 2 atoms will be dramatically released when the bond is broken. More generally, you may need to thermostat your system to compensate for energy changes resulting from broken bonds (and angles, dihedrals, impropers).

18.19.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes two statistics which it stores in a global vector of length 2, which can be accessed by various output commands. The vector values calculated by this fix are “intensive”.

These are the 2 quantities:

1. # of bonds broken on the most recent breakage timestep
2. cumulative # of bonds broken

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.19.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.19.6 Related commands

fix bond/create, fix bond/react, fix bond/swap, dump local, special_bonds

18.19.7 Default

The option defaults are prob = 1.0.
18.20 fix bond/create command

18.21 fix bond/create/angle command

18.21.1 Syntax

```
fix ID group-ID bond/create Nevery itype jtype Rmin bondtype keyword values ...
```

- ID, group-ID are documented in `fix` command
- bond/create = style name of this fix command
- Nevery = attempt bond creation every this many steps
- itype, jtype = atoms of itype can bond to atoms of jtype
- Rmin = 2 atoms separated by less than Rmin can bond (distance units)
- bondtype = type of created bonds
- zero or more keyword/value pairs may be appended to args
- keyword = `iparam` or `jparam` or `prob` or `atype` or `dtype` or `itype` or `aconstrain`

- `iparam` values = maxbond, newtype
  - maxbond = max # of bonds of bondtype the itype atom can have
  - newtype = change the itype atom to this type when maxbonds exist
- `jparam` values = maxbond, newtype
  - maxbond = max # of bonds of bondtype the jtype atom can have
  - newtype = change the jtype atom to this type when maxbonds exist
- `prob` values = fraction seed
  - fraction = create a bond with this probability if otherwise eligible
  - seed = random number seed (positive integer)
- `atype` value = angletype
  - angletype = type of created angles
- `dtype` value = dihedraltype
  - dihedraltype = type of created dihedrals
- `itype` value = impropertype
  - impropertype = type of created impropers
- `aconstrain` value = amin amax
  - amin = minimal angle at which new bonds can be created
  - amax = maximal angle at which new bonds can be created

```
18.21.3 Description

Create bonds between pairs of atoms as a simulation runs according to specified criteria. This can be used to model cross-linking of polymers, the formation of a percolation network, etc. In this context, a bond means an interaction between a pair of atoms computed by the \textit{bond_style} command. Once the bond is created it will be permanently in place. Optionally, the creation of a bond can also create angle, dihedral, and improper interactions that bond is part of. See the discussion of the \textit{atype}, \textit{dtype}, and \textit{itype} keywords below.

This is different than a \textit{pairwise} bond-order potential such as Tersoff or AIREBO which infers bonds and many-body interactions based on the current geometry of a small cluster of atoms and effectively creates and destroys bonds and higher-order many-body interactions from timestep to timestep as atoms move.

A check for possible new bonds is performed every \textit{Nevery} timesteps. If two atoms I,J are within a distance \textit{Rmin} of each other, if I is of atom type \textit{itype}, if J is of atom type \textit{jtype}, if both I and J are in the specified fix group, if a bond does not already exist between I and J, and if both I and J meet their respective \textit{maxbond} requirement (explained below), then I,J is labeled as a “possible” bond pair. If several atoms are close to an atom, it may have multiple possible bond partners. Every atom checks its list of possible bond partners and labels the closest such partner as its “sole” bond partner. After this is done, if atom I has atom J as its sole partner, and atom J has atom I as its sole partner, then the IJ bond is “eligible” to be formed.

Note that these rules mean an atom will only be part of at most one created bond on a given timestep. It also means that if atom I chooses atom J as its sole partner, but atom J chooses atom K is its sole partner (due to \textit{Rjk} < \textit{Rij}), then this means atom I will not form a bond on this timestep, even if it has other possible bond partners.

It is permissible to have \textit{itype} = \textit{jtype}. \textit{Rmin} must be \(\leq\) the pairwise cutoff distance between \textit{itype} and \textit{jtype} atoms, as defined by the \textit{pair_style} command.

The \textit{iparam} and \textit{jparam} keywords can be used to limit the bonding functionality of the participating atoms. Each atom keeps track of how many bonds of \textit{bondtype} it already has. If atom I of \textit{itype} already has \textit{maxbond} bonds (as set by the \textit{iparam} keyword), then it will not form any more. Likewise for atom J. If \textit{maxbond} is set to 0, then there is no limit on the number of bonds that can be formed with that atom.

The \textit{newtype} value for \textit{iparam} and \textit{jparam} can be used to change the atom type of atom I or J when it reaches \textit{maxbond} number of bonds of type \textit{bondtype}. This means it can now interact in a pairwise fashion with other atoms in a different way by specifying different \textit{pair_coeff} coefficients. If you do not wish the atom type to change, simply specify \textit{newtype} as \textit{itype} or \textit{jtype}.

The \textit{prob} keyword can also effect whether an eligible bond is actually created. The \textit{fraction} setting must be a value between 0.0 and 1.0. A uniform random number between 0.0 and 1.0 is generated and the eligible bond is only created if the random number < fraction.

The \textit{aconstrain} keyword is only available with the fix bond/create/angle command. It allows to specify a minimal and maximal angle \textit{amin} and \textit{amax} between the two prospective bonding partners and a third particle that is already bonded to one of the two partners. Such a criterion can be important when new angles are defined together with the formation of a new bond. Without a restriction on the permissible angle, and for stiffer angle potentials, very large energies can arise and lead to uncontrolled behavior.

Any bond that is created is assigned a bond type of \textit{bondtype}.

When a bond is created, data structures within LAMMPS that store bond topology are updated to reflect the creation. If the bond is part of new 3-body (angle) or 4-body (dihedral, improper) interactions, you can choose to create new angles, dihedrals, impropers as well, using the \textit{atype}, \textit{dtype}, and \textit{itype} keywords. All of these changes typically affect pairwise interactions between atoms that are now part of new bonds, angles, etc.

\textbf{Note: } One data structure that is not updated when a bond breaks are the molecule IDs stored by each atom. Even though two molecules become one molecule due to the created bond, all atoms in the new molecule retain their original molecule IDs.

18.21. \textit{fix bond/create/angle command}
If the \textit{atype} keyword is used and if an angle potential is defined via the \textit{angle_style} command, then any new 3-body interactions inferred by the creation of a bond will create new angles of type \textit{angletype}, with parameters assigned by the corresponding \textit{angle_coeff} command. Likewise, the \textit{dtype} and \textit{itype} keywords will create new dihedrals and impropers of type \textit{dihedraltype} and \textit{impropertype}.

\textbf{Note:} To create a new bond, the internal LAMMPS data structures that store this information must have space for it. When LAMMPS is initialized from a data file, the list of bonds is scanned and the maximum number of bonds per atom is tallied. If some atom will acquire more bonds than this limit as this fix operates, then the “extra bond per atom” parameter must be set to allow for it. Ditto for “extra angle per atom”, “extra dihedral per atom”, and “extra improper per atom” if angles, dihedrals, or impropers are being added when bonds are created. See the \texttt{read_data} or \texttt{create_box} command for more details. Note that a data file with no atoms can be used if you wish to add non-bonded atoms via the \texttt{create atoms} command, e.g. for a percolation simulation.

\textbf{Note:} LAMMPS stores and maintains a data structure with a list of the first, second, and third neighbors of each atom (within the bond topology of the system) for use in weighting pairwise interactions for bonded atoms. Note that adding a single bond always adds a new first neighbor but may also induce *many* new second and third neighbors, depending on the molecular topology of your system. The “extra special per atom” parameter must typically be set to allow for the new maximum total size (first + second + third neighbors) of this per-atom list. There are 2 ways to do this. See the \texttt{read_data} or \texttt{create_box} commands for details.

\textbf{Note:} Even if you do not use the \textit{atype}, \textit{dtype}, or \textit{itype} keywords, the list of topological neighbors is updated for atoms affected by the new bond. This in turn affects which neighbors are considered for pairwise interactions, using the weighting rules set by the \texttt{special_bonds} command. Consider a new bond created between atoms IJ. If J has a bonded neighbor K, then K becomes a second neighbor of I. Even if the \textit{atype} keyword is not used to create angle I-J-K, the pairwise interaction between I and K will be potentially turned off or weighted by the 1-3 weighting specified by the \texttt{special_bonds} command. This is the case even if the “angle yes” option was used with that command. The same is true for third neighbors (1-4 interactions), the \textit{dtype} keyword, and the “dihedral yes” option used with the \texttt{special_bonds} command.

Note that even if your simulation starts with no bonds, you must define a \textit{bond_style} and use the \texttt{bond_coeff} command to specify coefficients for the \textit{bondtype}. Similarly, if new atom types are specified by the \textit{iparam} or \textit{jparam} keywords, they must be within the range of atom types allowed by the simulation and pairwise coefficients must be specified for the new types.

Computationally, each timestep this fix operates, it loops over neighbor lists and computes distances between pairs of atoms in the list. It also communicates between neighboring processors to coordinate which bonds are created. Moreover, if any bonds are created, neighbor lists must be immediately updated on the same timestep. This is to insure that any pairwise interactions that should be turned “off” due to a bond creation, because they are now excluded by the presence of the bond and the settings of the \texttt{special_bonds} command, will be immediately recognized. All of these operations increase the cost of a timestep. Thus you should be cautious about invoking this fix too frequently.

You can dump out snapshots of the current bond topology via the \texttt{dump local} command.

\textbf{Note:} Creating a bond typically alters the energy of a system. You should be careful not to choose bond creation criteria that induce a dramatic change in energy. For example, if you define a very stiff harmonic bond and create it when 2 atoms are separated by a distance far from the equilibrium bond length, then the 2 atoms will oscillate dramatically when the bond is formed. More generally, you may need to thermostat your system to compensate for energy changes resulting from created bonds (and angles, dihedrals, impropers).
18.21.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix computes two statistics which it stores in a global vector of length 2, which can be accessed by various output commands. The vector values calculated by this fix are “intensive”.

These are the 2 quantities:

• (1) # of bonds created on the most recent creation timestep
• (2) cumulative # of bonds created

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.21.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.21.6 Related commands

fix bond/break, fix bond/react, fix bond/swap, dump local, special_bonds

18.21.7 Default

The option defaults are iparam = (0,itype), jparam = (0,jtype), and prob = 1.0.

18.22 fix bond/react command

18.22.1 Syntax

```
fix ID group-ID bond/react common_keyword values ...
   react react-ID react-group-ID Nevery Rmin Rmax template-ID(pre-reacted) template-ID(post-reacted) map_file individual_keyword values ...
   react react-ID react-group-ID Nevery Rmin Rmax template-ID(pre-reacted) template-ID(post-reacted) map_file individual_keyword values ...
   react react-ID react-group-ID Nevery Rmin Rmax template-ID(pre-reacted) template-ID(post-reacted) map_file individual_keyword values ...
   ... 
```

- ID, group-ID are documented in fix command.
- bond/react = style name of this fix command
- the common keyword/values may be appended directly after ‘bond/react’
- this applies to all reaction specifications (below)
- common_keyword = stabilization or reset_mol_ids
stabilization values = no or yes group-ID xmax
no = no reaction site stabilization (default)
yes = perform reaction site stabilization
  group-ID = user-assigned prefix for the dynamic group of atoms not
  currently involved in a reaction
  xmax = xmax value that is used by an internally-created nve/limit
  integrator
reset_mol_ids values = yes or no
yes = update molecule IDs based on new global topology (default)
no = do not update molecule IDs

- react = mandatory argument indicating new reaction specification
- react-ID = user-assigned name for the reaction
- react-group-ID = only atoms in this group are considered for the reaction
- Nevery = attempt reaction every this many steps
- Rmin = bonding pair atoms must be separated by more than Rmin to initiate reaction (distance units)
- Rmax = bonding pair atoms must be separated by less than Rmax to initiate reaction (distance units)
- template-ID(pre-reacted) = ID of a molecule template containing pre-reaction topology
- template-ID(post-reacted) = ID of a molecule template containing post-reaction topology
- map_file = name of file specifying corresponding atom-IDs in the pre- and post-reacted templates
- zero or more individual keyword/value pairs may be appended to each react argument
  - individual_keyword = prob or max_rxn or stabilize_steps or custom_charges

  prob values = fraction seed
  fraction = initiate reaction with this probability if otherwise eligible
  seed = random number seed (positive integer)
max_rxn value = N
  N = maximum number of reactions allowed to occur
stabilize_steps value = timesteps
  timesteps = number of timesteps to apply the internally-created nve/limit fix to reacting atoms
custom_charges value = no or fragmentID
  no = update all atomic charges (default)
  fragmentID = ID of molecule fragment whose charges are updated

18.22.2 Examples

```
18.22.3 Description

Initiate complex covalent bonding (topology) changes. These topology changes will be referred to as ‘reactions’ throughout this documentation. Topology changes are defined in pre- and post-reaction molecule templates and can include creation and deletion of bonds, angles, dihedrals, impropers, bond types, angle types, dihedral types, atom types, or atomic charges. In addition, reaction by-products or other molecules can be identified and deleted.

Fix bond/react does not use quantum mechanical (eg. fix qmmm) or pairwise bond-order potential (eg. Tersoff or AIREBO) methods to determine bonding changes a priori. Rather, it uses a distance-based probabilistic criteria to effect predetermined topology changes in simulations using standard force fields.

This fix was created to facilitate the dynamic creation of polymeric, amorphous or highly cross-linked systems. A suggested workflow for using this fix is: 1) identify a reaction to be simulated 2) build a molecule template of the reaction site before the reaction has occurred 3) build a molecule template of the reaction site after the reaction has occurred 4) create a map that relates the template-atom-IDs of each atom between pre- and post-reaction molecule templates 5) fill a simulation box with molecules and run a simulation with fix bond/react.

Only one ‘fix bond/react’ command can be used at a time. Multiple reactions can be simultaneously applied by specifying multiple react arguments to a single ‘fix bond/react’ command. This syntax is necessary because the ‘common keywords’ are applied to all reactions.

The stabilization keyword enables reaction site stabilization. Reaction site stabilization is performed by including reacting atoms in an internally-created fix nve/limit time integrator for a set number of timesteps given by the stabilize_steps keyword. While reacting atoms are being time integrated by the internal nve/limit, they are prevented from being involved in any new reactions. The xmax value keyword should typically be set to the maximum distance that non-reacting atoms move during the simulation.

Fix bond/react creates and maintains two important dynamic groups of atoms when using the stabilization keyword. The first group contains all atoms currently involved in a reaction; this group is automatically thermostatted by an internally-created nve/limit integrator. The second group contains all atoms currently not involved in a reaction. This group should be used by a thermostat in order to time integrate the system. The name of this group of non-reacting atoms is created by appending `_REACT` to the group-ID argument of the stabilization keyword, as shown in the second example above.

Note: When using reaction stabilization, you should generally not have a separate thermostat which acts on the ‘all’ group.

The group-ID set using the stabilization keyword can be an existing static group or a previously-unused group-ID. It cannot be specified as ‘all’. If the group-ID is previously unused, the fix bond/react command creates a dynamic group that is initialized to include all atoms. If the group-ID is that of an existing static group, the group is used as the parent group of new, internally-created dynamic group. In both cases, this new dynamic group is named by appending '_REACT' to the group-ID, e.g. nvt_grp_REACT. By specifying an existing group, you may thermostat constant-topology parts of your system separately. The dynamic group contains only atoms not involved in a reaction at a given timestep, and therefore should be used by a subsequent system-wide time integrator such as nvt, npt, or nve, as shown in the second example above (full examples can be found at examples/USER/reaction). The time integration command should be placed after the fix bond/react command due to the internal dynamic grouping performed by fix bond/react.

Note: If the group-ID is an existing static group, react-group-IDs should also be specified as this static group, or a
The reset_mol_ids keyword invokes the reset_mol_ids command after a reaction occurs, to ensure that molecule IDs are consistent with the new bond topology. The group-ID used for reset_mol_ids is the group-ID for this fix. Resetting molecule IDs is necessarily a global operation, and so can be slow for very large systems.

The following comments pertain to each react argument (in other words, can be customized for each reaction, or reaction step):

A check for possible new reaction sites is performed every Nevery timesteps. Nevery can be specified with an equal-style variable, whose value is rounded up to the nearest integer.

Three physical conditions must be met for a reaction to occur. First, a bonding atom pair must be identified within the reaction distance cutoffs. Second, the topology surrounding the bonding atom pair must match the topology of the pre-reaction template. Finally, any reaction constraints listed in the map file (see below) must be satisfied. If all of these conditions are met, the reaction site is eligible to be modified to match the post-reaction template.

A bonding atom pair will be identified if several conditions are met. First, a pair of atoms I,J within the specified react-group-ID of type itype and jtype must be separated by a distance between $R_{\text{min}}$ and $R_{\text{max}}$. $R_{\text{min}}$ and $R_{\text{max}}$ can be specified with equal-style variables. For example, these reaction cutoffs can be a function of the reaction conversion using the following commands:

```
variable rmax equal 0 # initialize variable before bond/react
fix myrxn all bond/react react myrxn1 all 1 0 v_rmax mol1 mol2 map_file.txt
variable rmax equal 3+f_myrxn[1]/100 # arbitrary function of reaction count
```

It is possible that multiple bonding atom pairs are identified: if the bonding atoms in the pre-reacted template are 1-2 neighbors, i.e. directly bonded, the farthest bonding atom partner is set as its bonding partner; otherwise, the closest potential partner is chosen. Then, if both an atom I and atom J have each other as their bonding partners, these two atoms are identified as the bonding atom pair of the reaction site. Once this unique bonding atom pair is identified for each reaction, there could two or more reactions that involve a given atom on the same timestep. If this is the case, only one such reaction is permitted to occur. This reaction is chosen randomly from all potential reactions. This capability allows e.g. for different reaction pathways to proceed from identical reaction sites with user-specified probabilities.

The pre-reacted molecule template is specified by a molecule command. This molecule template file contains a sample reaction site and its surrounding topology. As described below, the bonding atom pairs of the pre-reacted template are specified by atom ID in the map file. The pre-reacted molecule template should contain as few atoms as possible while still completely describing the topology of all atoms affected by the reaction (which includes all atoms that change atom type or connectivity, and all bonds that change bond type). For example, if the force field contains dihedrals, the pre-reacted template should contain any atom within three bonds of reacting atoms.

Some atoms in the pre-reacted template that are not reacting may have missing topology with respect to the simulation. For example, the pre-reacted template may contain an atom that, in the simulation, is currently connected to the rest of a long polymer chain. These are referred to as edge atoms, and are also specified in the map file. All pre-reaction template atoms should be linked to a bonding atom, via at least one path that does not involve edge atoms. When the pre-reaction template contains edge atoms, not all atoms, bonds, charges, etc. specified in the reaction templates will be updated. Specifically, topology that involves only atoms that are ‘too near’ to template edges will not be updated. The definition of ‘too near the edge’ depends on which interactions are defined in the simulation. If the simulation has defined dihedrals, atoms within two bonds of edge atoms are considered ‘too near the edge.’ If the simulation defines angles, but not dihedrals, atoms within one bond of edge atoms are considered ‘too near the edge.’ If just bonds are defined, only edge atoms are considered ‘too near the edge.’

Note: Small molecules, i.e. ones that have all their atoms contained within the reaction templates, never have edge atoms.
Note that some care must be taken when building a molecule template for a given simulation. All atom types in the pre-reacted template must be the same as those of a potential reaction site in the simulation. A detailed discussion of matching molecule template atom types with the simulation is provided on the `molecule` command page.

The post-reacted molecule template contains a sample of the reaction site and its surrounding topology after the reaction has occurred. It must contain the same number of atoms as the pre-reacted template. A one-to-one correspondence between the atom IDs in the pre- and post-reacted templates is specified in the map file as described below. Note that during a reaction, an atom, bond, etc. type may change to one that was previously not present in the simulation. These new types must also be defined during the setup of a given simulation. A discussion of correctly handling this is also provided on the `molecule` command page.

**Note:** When a reaction occurs, it is possible that the resulting topology/atom (e.g., special bonds, dihedrals, etc.) exceeds that of the existing system and reaction templates. As when inserting molecules, enough space for this increased topology/atom must be reserved by using the relevant “extra” keywords to the `read_data` or `create_box` commands.

The map file is a text document with the following format:

A map file has a header and a body. The header of map file the contains one mandatory keyword and four optional keywords. The mandatory keyword is ‘equivalences’:

```
N equivalences = # of atoms N in the reaction molecule templates
```

The optional keywords are ‘edgeIDs’, ‘deleteIDs’, ‘chiralIDs’ and ‘constraints’:

```
N edgeIDs = # of edge atoms N in the pre-reacted molecule template
N deleteIDs = # of atoms N that are specified for deletion
N chiralIDs = # of specified chiral centers N
N constraints = # of specified reaction constraints N
```

The body of the map file contains two mandatory sections and four optional sections. The first mandatory section begins with the keyword ‘BondingIDs’ and lists the atom IDs of the bonding atom pair in the pre-reacted molecule template. The second mandatory section begins with the keyword ‘Equivalences’ and lists a one-to-one correspondence between atom IDs of the pre- and post-reacted templates. The first column is an atom ID of the pre-reacted molecule template, and the second column is the corresponding atom ID of the post-reacted molecule template. The first optional section begins with the keyword ‘EdgeIDs’ and lists the atom IDs of edge atoms in the pre-reacted molecule template. The second optional section begins with the keyword ‘DeleteIDs’ and lists the atom IDs of pre-reaction template atoms to delete. The third optional section begins with the keyword ‘ChiralIDs’ lists the atom IDs of chiral atoms whose handedness should be enforced. The fourth optional section begins with the keyword ‘Constraints’ and lists additional criteria that must be satisfied in order for the reaction to occur. Currently, there are five types of constraints available, as discussed below: ‘distance’, ‘angle’, ‘dihedral’, ‘arrhenius’, and ‘rmsd’.

A sample map file is given below:

```
# this is a map file
7 equivalences
2 edgeIDs

BondingIDs
3
5

EdgeIDs
```

(continues on next page)
The handedness of atoms that are chiral centers can be enforced by listing their IDs in the ChiralIDs section. A chiral atom must be bonded to four atoms with mutually different atom types. This feature uses the coordinates and types of the involved atoms in the pre-reaction template to determine handedness. Three atoms bonded to the chiral center are arbitrarily chosen, to define an oriented plane, and the relative position of the fourth bonded atom determines the chiral center’s handedness.

Any number of additional constraints may be specified in the Constraints section of the map file. The constraint of type ‘distance’ has syntax as follows:

```
distance ID1 ID2 rmin rmax
```

where ‘distance’ is the required keyword, ID1 and ID2 are pre-reaction atom IDs (or molecule-fragment IDs, see below), and these two atoms must be separated by a distance between \( r_{\text{min}} \) and \( r_{\text{max}} \) for the reaction to occur.

The constraint of type ‘angle’ has the following syntax:

```
angle ID1 ID2 ID3 amin amax
```

where ‘angle’ is the required keyword, ID1, ID2 and ID3 are pre-reaction atom IDs (or molecule-fragment IDs, see below), and these three atoms must form an angle between \( a_{\text{min}} \) and \( a_{\text{max}} \) for the reaction to occur (where ID2 is the central atom). Angles must be specified in degrees. This constraint can be used to enforce a certain orientation between reacting molecules.

The constraint of type ‘dihedral’ has the following syntax:

```
dihedral ID1 ID2 ID3 ID4 amin amax amin2 amax2
```

where ‘dihedral’ is the required keyword, and ID1, ID2, ID3 and ID4 are pre-reaction atom IDs (or molecule-fragment IDs, see below). Dihedral angles are calculated in the interval \((-180, 180]\). Refer to the dihedral style documentation for further details on convention. If \( a_{\text{min}} \) is less than \( a_{\text{max}} \), these four atoms must form a dihedral angle greater than \( a_{\text{min}} \) and less than \( a_{\text{max}} \) for the reaction to occur. If \( a_{\text{min}} \) is greater than \( a_{\text{max}} \), these four atoms must form a dihedral angle greater than \( a_{\text{min}} \) or less than \( a_{\text{max}} \) for the reaction to occur. Angles must be specified in degrees. Optionally, a second range of permissible angles \( a_{\text{min2}}-a_{\text{max2}} \) can be specified.

For the ‘distance’, ‘angle’, and ‘dihedral’ constraints (explained above), atom IDs can be replaced by pre-reaction molecule-fragment IDs. The molecule-fragment ID must begin with a letter. The location of the ID is the geometric center of all atom positions in the fragment. The molecule fragment must have been defined in the `molecule` command for the pre-reaction template.

The constraint of type ‘arrhenius’ imposes an additional reaction probability according to the temperature-dependent Arrhenius equation:

\[
k = AT^n e^{-\frac{E_a}{k_B T}}
\]

The Arrhenius constraint has the following syntax:
arrhenius A n E_a seed

where 'arrhenius' is the required keyword, \(A\) is the pre-exponential factor, \(n\) is the exponent of the temperature dependence, \(E_a\) is the activation energy (units of energy), and seed is a random number seed. The temperature is defined as the instantaneous temperature averaged over all atoms in the reaction site, and is calculated in the same manner as for example compute temp/chunk. Currently, there are no options for additional temperature averaging or velocity-biased temperature calculations. A uniform random number between 0 and 1 is generated using seed; if this number is less than the result of the Arrhenius equation above, the reaction is permitted to occur.

The constraint of type 'rmsd' has the following syntax:

rmsd RMSDmax molfragment

where 'rmsd' is the required keyword, and \(RMSDmax\) is the maximum root-mean-square deviation between atom positions of the pre-reaction template and the local reaction site (distance units), after optimal translation and rotation of the pre-reaction template. Optionally, the name of a molecule fragment (of the pre-reaction template) can be specified by molfragment. If a molecule fragment is specified, only atoms that are part of this molecule fragment are used to determine the RMSD. A molecule fragment must have been defined in the molecule command for the pre-reaction template. For example, the molecule fragment could consist of only the backbone atoms of a polymer chain. This constraint can be used to enforce a specific relative position and orientation between reacting molecules.

Once a reaction site has been successfully identified, data structures within LAMMPS that store bond topology are updated to reflect the post-reacted molecule template. All force fields with fixed bonds, angles, dihedrals or impropers are supported.

A few capabilities to note: 1) You may specify as many react arguments as desired. For example, you could break down a complicated reaction mechanism into several reaction steps, each defined by its own react argument. 2) While typically a bond is formed or removed between the bonding atom pairs specified in the pre-reacted molecule template, this is not required. 3) By reversing the order of the pre- and post-reacted molecule templates in another react argument, you can allow for the possibility of one or more reverse reactions.

The optional keywords deal with the probability of a given reaction occurring as well as the stable equilibration of each reaction site as it occurs:

The prob keyword can affect whether or not an eligible reaction actually occurs. The fraction setting must be a value between 0.0 and 1.0, and can be specified with an equal-style variable. A uniform random number between 0.0 and 1.0 is generated and the eligible reaction only occurs if the random number is less than the fraction. Up to \(N\) reactions are permitted to occur, as optionally specified by the max_rxn keyword.

The stabilize_steps keyword allows for the specification of how many timesteps a reaction site is stabilized before being returned to the overall system thermostat. In order to produce the most physical behavior, this 'reaction site equilibration time' should be tuned to be as small as possible while retaining stability for a given system or reaction step. After a limited number of case studies, this number has been set to a default of 60 timesteps. Ideally, it should be individually tuned for each fix reaction step. Note that in some situations, decreasing rather than increasing this parameter will result in an increase in stability.

The custom_charges keyword can be used to specify which atoms' atomic charges are updated. When the value is set to 'no,' all atomic charges are updated to those specified by the post-reaction template (default). Otherwise, the value should be the name of a molecule fragment defined in the pre-reaction molecule template. In this case, only the atomic charges of atoms in the molecule fragment are updated.

A few other considerations:

Many reactions result in one or more atoms that are considered unwanted by-products. Therefore, bond/react provides the option to delete a user-specified set of atoms. These pre-reaction atoms are identified in the map file. A deleted atom must still be included in the post-reaction molecule template, in which it cannot be bonded to an atom that is not deleted. In addition to deleting unwanted reaction by-products, this feature can be used to remove specific topologies, such as small rings, that may be otherwise indistinguishable.
Optionally, you can enforce additional behaviors on reacting atoms. For example, it may be beneficial to force reacting atoms to remain at a certain temperature. For this, you can use the internally-created dynamic group named “bond_react_MASTER_group”, which consists of all atoms currently involved in a reaction. For example, adding the following command would add an additional thermostat to the group of all currently-reacting atoms:

```
fix 1 bond_react_MASTER_group temp/rescale 1 300 300 10 1
```

**Note:** This command must be added after the fix bond/react command, and will apply to all reactions.

Computationally, each timestep this fix operates, it loops over neighbor lists (for bond-forming reactions) and computes distances between pairs of atoms in the list. It also communicates between neighboring processors to coordinate which bonds are created and/or removed. All of these operations increase the cost of a timestep. Thus you should be cautious about invoking this fix too frequently.

You can dump out snapshots of the current bond topology via the dump local command.

### 18.22.4 Restart, fix_modify, output, run start/stop, minimize info

Cumulative reaction counts for each reaction are written to binary restart files. These values are associated with the reaction name (react-ID). Additionally, internally-created per-atom properties are stored to allow for smooth restarts. None of the fix_modify options are relevant to this fix.

This fix computes one statistic for each react argument that it stores in a global vector, of length ‘number of react arguments’, that can be accessed by various output commands. The vector values calculated by this fix are “intensive”.

These is 1 quantity for each react argument:

- (1) cumulative # of reactions occurred

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

When fix bond/react is ‘unfixed,’ all internally-created groups are deleted. Therefore, fix bond/react can only be unfixed after unfixing all other fixes that use any group created by fix bond/react.

### 18.22.5 Restrictions

This fix is part of the USER-REACTION package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.23 fix bond/swap command

18.23.1 Syntax

```
fix ID group-ID bond/swap Nevery fraction cutoff seed
```

- ID, group-ID are documented in fix command
- bond/swap = style name of this fix command
- Nevery = attempt bond swapping every this many steps
- fraction = fraction of group atoms to consider for swapping
- cutoff = distance at which swapping will be considered (distance units)
- seed = random # seed (positive integer)

18.23.2 Examples

```
fix 1 all bond/swap 50 0.5 1.3 598934
```

18.23.3 Description

In a simulation of polymer chains, this command attempts to swap bonds between two different chains, effectively grafting the end of one chain onto another chain and vice versa. This is done via Monte Carlo rules using the Boltzmann acceptance criterion. The purpose is to equilibrate the polymer chain conformations more rapidly than dynamics alone would do it, by enabling instantaneous large conformational changes in a dense polymer melt. The polymer chains should thus more rapidly converge to the proper end-to-end distances and radii of gyration. It is designed for use with systems of FENE or harmonic bead-spring polymer chains where each polymer is a linear chain of monomers, but LAMMPS does not enforce this requirement, i.e. any bond_style can be used.

A schematic of the kinds of bond swaps that can occur is shown here:

![Schematic of bond swaps](image)

On the left, the red and blue chains have two monomers A1 and B1 close to each other, which are currently bonded to monomers A2 and B2 respectively within their own chains. The bond swap operation will attempt to delete the
A1-A2 and B1-B2 bonds and replace them with A1-B2 and B1-A2 bonds. If the swap is energetically favorable, the
two chains on the right are the result and each polymer chain has undergone a dramatic conformational change. This
reference, (Sides) provides more details on how the algorithm works and its application:

The bond swapping operation is invoked every Nevery timesteps. If any bond is swapped, a re-build of the neighbor
lists is triggered, since a swap alters the list of which neighbors are considered for pairwise interaction. At each
invocation, each processor considers a random specified fraction of its atoms as potential swapping monomers for this
timestep. Choosing a small fraction value can reduce the likelihood of a reverse swap occurring soon after an initial
swap.

For each monomer A1, its neighbors are examined to find a possible B1 monomer. Both A1 and B1 must be in the fix
group, their separation must be less than the specified cutoff, and the molecule IDs of A1 and B1 must be the same
(see below). If a suitable partner is found, the energy change due to swapping the 2 bonds is computed. This includes
changes in pairwise, bond, and angle energies due to the altered connectivity of the 2 chains. Dihedral and improper
interactions are not allowed to be defined when this fix is used.

If the energy decreases due to the swap operation, the bond swap is accepted. If the energy increases it is accepted
with probability exp(-delta/kT) where delta is the increase in energy, k is the Boltzmann constant, and T is the current
temperature of the system. Whether the swap is accepted or rejected, no other swaps are attempted by this processor
on this timestep.

The criterion for matching molecule IDs is how bond swaps performed by this fix conserve chain length. To use this
features you must setup the molecule IDs for your polymer chains in a certain way, typically in the data file, read by
the read_data command. Consider a system of 6-mer chains. You have 2 choices. If the molecule IDs for monomers
on each chain are set to 1,2,3,4,5,6 then swaps will conserve chain length. For a particular monomer there will be only
one other monomer on another chain which is a potential swap partner. If the molecule IDs for monomers on each
chain are set to 1,2,3,3,2,1 then swaps will conserve chain length but swaps will be able to occur at either end of a
chain. Thus for a particular monomer there will be 2 possible swap partners on another chain. In this scenario, swaps
can also occur within a single chain, i.e. the two ends of a chain swap with each other.

Note: If your simulation uses molecule IDs in the usual way, where all monomers on a single chain are assigned the
same ID (different for each chain), then swaps will only occur within the same chain. If you assign the same molecule
ID to all monomers in all chains then inter-chain swaps will occur, but they will not conserve chain length. Neither of
these scenarios is probably what you want for this fix.

Note: When a bond swap occurs the image flags of monomers in the new polymer chains can become inconsistent.
See the dump command for a discussion of image flags. This is not an issue for running dynamics, but can affect
calculation of some diagnostic quantities or the printing of unwrapped coordinates to a dump file.

This fix computes a temperature each time it is invoked for use by the Boltzmann criterion. To do this, the fix creates
its own compute of style temp, as if this command had been issued:

```
compute fix-ID_temp all temp
```

See the compute temp command for details. Note that the ID of the new compute is the fix-ID with underscore +
“temp” appended and the group for the new compute is “all”, so that the temperature of the entire system is used.

Note that this is NOT the compute used by thermodynamic output (see the thermo_style command) with ID =
thermo_temp. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via
the compute_modify command or print this temperature during thermodynamic output via the thermo_style custom
command using the appropriate compute-ID. It also means that changing attributes of thermo_temp will have no effect
on this fix.
18.23.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior. Also note that each processor generates possible swaps independently of other processors. Thus if you repeat the same simulation on a different number of processors, the specific swaps performed will be different.

The fix_modify temp option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used to compute the temperature for the Boltzmann criterion.

This fix computes two statistical quantities as a global 2-vector of output, which can be accessed by various output commands. The first component of the vector is the cumulative number of swaps performed by all processors. The second component of the vector is the cumulative number of swaps attempted (whether accepted or rejected). Note that a swap “attempt” only occurs when swap partners meeting the criteria described above are found on a particular timestep. The vector values calculated by this fix are “intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.23.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The settings of the “special_bond” command must be 0,1,1 in order to use this fix, which is typical of bead-spring chains with FENE or harmonic bonds. This means that pairwise interactions between bonded atoms are turned off, but are turned on between atoms two or three hops away along the chain backbone.

Currently, energy changes in dihedral and improper interactions due to a bond swap are not considered. Thus a simulation that uses this fix cannot use a dihedral or improper potential.

18.24.3 Description

Apply an external pressure or stress tensor to the simulation box during an energy minimization. This allows the box size and shape to vary during the iterations of the minimizer so that the final configuration will be both an energy minimum for the potential energy of the atoms, and the system pressure tensor will be close to the specified external tensor. Conceptually, specifying a positive pressure is like squeezing on the simulation box; a negative pressure typically allows the box to expand.

The external pressure tensor is specified using one or more of the iso, aniso, tri, x, y, z, xy, xz, yz, and couple keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during the minimization.

Orthogonal simulation boxes have 3 adjustable dimensions (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable dimensions (x,y,z,xy,xz,yz). The create_box, read data, and read_restart commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

The target pressures $P_{target}$ for each of the 6 components of the stress tensor can be specified independently via the x, y, z, xy, xz, yz keywords, which correspond to the 6 simulation box dimensions. For example, if the y keyword is used, the y-box length will change during the minimization. If the xy keyword is used, the xy tilt factor will change. A box dimension will not change if that component is not specified.

Note that in order to use the xy, xz, or yz keywords, the simulation box must be triclinic, even if its initial tilt factors are 0.0.

When the size of the simulation box changes, all atoms are re-scaled to new positions, unless the keyword dilate is specified with a value of partial, in which case only the atoms in the fix group are re-scaled. This can be useful for leaving the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid.
The *scaleyz*, *scalexz*, and *scalexy* keywords control whether or not the corresponding tilt factors are scaled with the associated box dimensions when relaxing triclinic periodic cells. The default values *yes* will turn on scaling, which corresponds to adjusting the linear dimensions of the cell while preserving its shape. Choosing *no* ensures that the tilt factors are not scaled with the box dimensions. See below for restrictions and default values in different situations. In older versions of LAMMPS, scaling of tilt factors was not performed. The old behavior can be recovered by setting all three scale keywords to *no*.

The *fixedpoint* keyword specifies the fixed point for cell relaxation. By default, it is the center of the box. Whatever point is chosen will not move during the simulation. For example, if the lower periodic boundaries pass through (0,0,0), and this point is provided to *fixedpoint*, then the lower periodic boundaries will remain at (0,0,0), while the upper periodic boundaries will move twice as far. In all cases, the particle positions at each iteration are unaffected by the chosen value, except that all particles are displaced by the same amount, different on each iteration.

**Note:** Applying an external pressure to tilt dimensions $xy$, $xz$, $yz$ can sometimes result in arbitrarily large values of the tilt factors, i.e. a dramatically deformed simulation box. This typically indicates that there is something badly wrong with how the simulation was constructed. The two most common sources of this error are applying a shear stress to a liquid system or specifying an external shear stress tensor that exceeds the yield stress of the solid. In either case the minimization may converge to a bogus conformation or not converge at all. Also note that if the box shape tilts to an extreme shape, LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor’s irregular-shaped sub-domain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

**Note:** Performing a minimization with this fix is not a mathematically well-defined minimization problem. This is because the objective function being minimized changes if the box size/shape changes. In practice this means the minimizer can get “stuck” before you have reached the desired tolerance. The solution to this is to restart the minimizer from the new adjusted box size/shape, since that creates a new objective function valid for the new box size/shape. Repeat as necessary until the box size/shape has reached its new equilibrium.

The *couple* keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, $xz$ means the $P_{xx}$ and $P_{zz}$ components of the stress tensor are coupled. $Xyz$ means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The $P_{target}$ values for any coupled dimensions must be identical. *Couple xyz* can be used for a 2d simulation; the $z$ dimension is simply ignored.

The *iso*, *aniso*, and *tri* keywords are simply shortcuts that are equivalent to specifying several other keywords together. The keyword *iso* means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “iso $P_{target}$” is the same as specifying these 4 keywords:

```plaintext
x $P_{target}$
y $P_{target}$
z $P_{target}$
couple xyz
```

The keyword *aniso* means $x$, $y$, and $z$ dimensions are controlled independently using the $P_{xx}$, $P_{yy}$, and $P_{zz}$ components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “aniso $P_{target}$” is the same as specifying these 4 keywords:
The keyword *tri* means *x*, *y*, *z*, *xy*, *xz*, and *yz* dimensions are controlled independently using their individual stress components as the driving forces, and the specified scalar pressure as the external normal stress. Using “tri Ptarget” is the same as specifying these 7 keywords:

<table>
<thead>
<tr>
<th>x Ptarget</th>
<th>y Ptarget</th>
<th>z Ptarget</th>
</tr>
</thead>
<tbody>
<tr>
<td>xy 0.0</td>
<td>yz 0.0</td>
<td>xz 0.0</td>
</tr>
<tr>
<td>couple none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The *vmax* keyword can be used to limit the fractional change in the volume of the simulation box that can occur in one iteration of the minimizer. If the pressure is not settling down during the minimization this can be because the volume is fluctuating too much. The specified fraction must be greater than 0.0 and should be << 1.0. A value of 0.001 means the volume cannot change by more than 1/10 of a percent in one iteration when *couple xyz* has been specified. For any other case it means no linear dimension of the simulation box can change by more than 1/10 of a percent.

With this fix, the potential energy used by the minimizer is augmented by an additional energy provided by the fix. The overall objective function then is:

\[
E = U + P_t (V - V_0) + E_{strain}
\]

where \(U\) is the system potential energy, \(P_t\) is the desired hydrostatic pressure, \(V\) and \(V_0\) are the system and reference volumes, respectively. \(E_{strain}\) is the strain energy expression proposed by Parrinello and Rahman (*Parrinello1981*). Taking derivatives of \(E\) w.r.t. the box dimensions, and setting these to zero, we find that at the minimum of the objective function, the global system stress tensor \(P\) will satisfy the relation:

\[
P = P_t I + S_t (h_0^{-1})^T h_{0d}
\]

where \(I\) is the identity matrix, \(h_0\) is the box dimension tensor of the reference cell, and \(h_{0d}\) is the diagonal part of \(h_0\). \(S_t\) is a symmetric stress tensor that is chosen by LAMMPS so that the upper-triangular components of \(P\) equal the stress tensor specified by the user.

This equation only applies when the box dimensions are equal to those of the reference dimensions. If this is not the case, then the converged stress tensor will not equal that specified by the user. We can resolve this problem by periodically resetting the reference dimensions. The keyword *nreset* controls how often this is done. If this keyword is not used, or is given a value of zero, then the reference dimensions are set to those of the initial simulation domain and are never changed. A value of *nstep* means that every *nstep* minimization steps, the reference dimensions are set to those of the current simulation domain. Note that resetting the reference dimensions changes the objective function and gradients, which sometimes causes the minimization to fail. This can be resolved by changing the value of *nreset*, or simply continuing the minimization from a restart file.

**Note:** As normally computed, pressure includes a kinetic- energy or temperature-dependent component; see the *compute pressure* command. However, atom velocities are ignored during a minimization, and the applied pressure(s) specified with this command are assumed to only be the virial component of the pressure (the non-kinetic portion). Thus if atoms have a non-zero temperature and you print the usual thermodynamic pressure, it may not appear the
system is converging to your specified pressure. The solution for this is to either (a) zero the velocities of all atoms before performing the minimization, or (b) make sure you are monitoring the pressure without its kinetic component. The latter can be done by outputting the pressure from the pressure compute this command creates (see below) or a pressure compute you define yourself.

**Note:** Because pressure is often a very sensitive function of volume, it can be difficult for the minimizer to equilibrate the system the desired pressure with high precision, particularly for solids. Some techniques that seem to help are (a) use the “min_modify line quadratic” option when minimizing with box relaxations, (b) minimize several times in succession if need be, to drive the pressure closer to the target pressure, (c) relax the atom positions before relaxing the box, and (d) relax the box to the target hydrostatic pressure before relaxing to a target shear stress state. Also note that some systems (e.g. liquids) will not sustain a non-hydrostatic applied pressure, which means the minimizer will not converge.

This fix computes a temperature and pressure each timestep. The temperature is used to compute the kinetic contribution to the pressure, even though this is subsequently ignored by default. To do this, the fix creates its own computes of style “temp” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp group-ID temp
compute fix-ID_press group-ID pressure fix-ID_temp virial
```

See the `compute temp` and `compute pressure` commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is the same as the fix group. Also note that the pressure compute does not include a kinetic component.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp` and `thermo_press`. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

### 18.24.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The `fix_modify temp` and `press` options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its temperature and pressure calculation, as described above. Note that as described above, if you assign a pressure compute to this fix that includes a kinetic energy component it will affect the minimization, most likely in an undesirable way.

**Note:** If both the `temp` and `press` keywords are used in a single thermo_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a `pressure compute` defines its own temperature compute as an argument when it is specified. The `temp` keyword will override this (for the pressure compute being used by fix_box/relax), but only if the `temp` keyword comes after the `press` keyword. If the `temp` keyword comes before the `press` keyword, then the new pressure compute specified by the `press` keyword will be unaffected by the `temp` setting.

This fix computes a global scalar which can be accessed by various `output commands`. The scalar is the pressure-volume energy, plus the strain energy, if it exists, as described above. The energy values reported at the end of a
minimization run under “Minimization stats” include this energy, and so differ from what LAMMPS normally reports as potential energy. This fix does not support the fix_modify energy option, because that would result in double-counting of the fix energy in the minimization energy. Instead, the fix energy can be explicitly added to the potential energy using one of these two variants:

```plaintext
variable emin equal pe+f_1
variable emin equal pe+f_1/atoms
```

No parameter of this fix can be used with the start/stop keywords of the run command.

This fix is invoked during energy minimization, but not for the purpose of adding a contribution to the energy or forces being minimized. Instead it alters the simulation box geometry as described above.

### 18.24.5 Restrictions

Only dimensions that are available can be adjusted by this fix. Non-periodic dimensions are not available. z, xz, and yz, are not available for 2D simulations. xy, xz, and yz are only available if the simulation domain is non-orthogonal. The create_box, read data, and read_restart commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

The scaleyz yes and scalexz yes keyword/value pairs can not be used for 2D simulations. scaleyz yes, scalexz yes, and scalexy yes options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords tri, yz, xz, and xy.

### 18.24.6 Related commands

fix npt, minimize

### 18.24.7 Default

The keyword defaults are dilate = all, vmax = 0.0001, nreset = 0.

### 18.25 fix client/md command

#### 18.25.1 Syntax

```plaintext
fix ID group-ID client/md
```

- ID, group-ID are documented in fix command
- client/md = style name of this fix command
18.25.2 Examples

```plaintext
fix 1 all client/md
```

18.25.3 Description

This fix style enables LAMMPS to run as a “client” code and communicate each timestep with a separate “server”
code to perform an MD simulation together.

The Howto client/server doc page gives an overview of client/server coupling of LAMMPS with another code where
one code is the “client” and sends request messages to a “server” code. The server responds to each request with a
reply message. This enables the two codes to work in tandem to perform a simulation.

When using this fix, LAMMPS (as the client code) passes the current coordinates of all particles to the server code
each timestep, which computes their interaction, and returns the energy, forces, and virial for the interacting particles
to LAMMPS, so it can complete the timestep.

Note that the server code can be a quantum code, or another classical MD code which encodes a force field (pair_style
in LAMMPS lingo) which LAMMPS does not have. In the quantum case, this fix is a mechanism for running ab initio
MD with quantum forces.

The group associated with this fix is ignored.

The protocol and units for message format and content that LAMMPS exchanges with the server code is defined on
the server md doc page.

Note that when using LAMMPS as an MD client, your LAMMPS input script should not normally contain force field
commands, like a pair_style, bond_style, or kspace_style command. However it is possible for a server code to only
compute a portion of the full force-field, while LAMMPS computes the remaining part. Your LAMMPS script can
also specify boundary conditions or force constraints in the usual way, which will be added to the per-atom forces
returned by the server code.

See the examples/message directory for example scripts where LAMMPS is both the “client” and/or “server” code for
this kind of client/server MD simulation. The examples/message/README file explains how to launch LAMMPS
and another code in tandem to perform a coupled simulation.

18.25.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the potential energy computed by the server application to
the system’s potential energy as part of thermodynamic output.

The fix_modify virial option is supported by this fix to add the server application’s contribution to the system’s virial
as part of thermodynamic output. The default is virial yes.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the potential
energy discussed above. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during
energy minimization.
18.25.5 Restrictions

This fix is part of the MESSAGE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

A script that uses this command must also use the message command to setup and shut down the messaging protocol with the server code.

18.25.6 Related commands

message, server

fix_modify myCMAP energy yes
```

18.26.3 Description

This command enables CMAP cross-terms to be added to simulations which use the CHARMM force field. These are relevant for any CHARMM model of a peptide or protein sequences that is 3 or more amino-acid residues long; see (Buck) and (Brooks) for details, including the analytic energy expressions for CMAP interactions. The CMAP cross-terms add additional potential energy contributions to pairs of overlapping phi-psi dihedrals of amino-acids, which are important to properly represent their conformational behavior.

The examples/cmap directory has a sample input script and data file for a small peptide, that illustrates use of the fix cmap command.

As in the example above, this fix should be used before reading a data file that contains a listing of CMAP interactions. The filename specified should contain the CMAP parameters for a particular version of the CHARMM force field. Two such files are including in the lammps/potentials directory: charmm22.cmap and charmm36.cmap.

The data file read by the "read_data" must contain the topology of all the CMAP interactions, similar to the topology data for bonds, angles, dihedrals, etc. Specially it should have a line like this in its header section:
N crossterms

where \( N \) is the number of CMAP cross-terms. It should also have a section in the body of the data file like this with \( N \) lines:

<table>
<thead>
<tr>
<th>CMAP</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>N</td>
</tr>
</tbody>
</table>

The first column is an index from 1 to \( N \) to enumerate the CMAP terms; it is ignored by LAMMPS. The second column is the “type” of the interaction; it is an index into the CMAP force field file. The remaining 5 columns are the atom IDs of the atoms in the two 4-atom dihedrals that overlap to create the CMAP 5-body interaction. Note that the “crossterm” and “CMAP” keywords for the header and body sections match those specified in the read_data command following the data file name; see the read_data doc page for more details.

A data file containing CMAP cross-terms can be generated from a PDB file using the charmm2lammps.pl script in the tools/ch2lmp directory of the LAMMPS distribution. The script must be invoked with the optional “-cmap” flag to do this; see the tools/ch2lmp/README file for more information.

The potential energy associated with CMAP interactions can be output as described below. It can also be included in the total potential energy of the system, as output by the thermo_style command, if the fix_modify energy command is used, as in the example above. See the note below about how to include the CMAP energy when performing an energy minimization.

---

**18.26.4 Restart, fix_modify, output, run start/stop, minimize info**

This fix writes the list of CMAP cross-terms to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify energy option is supported by this fix to add the potential “energy” of the CMAP interactions system’s potential energy as part of thermodynamic output.

The fix_modify virial option is supported by this fix to add the contribution due to the interaction between atoms to the system’s virial as part of thermodynamic output. The default is virial yes

This fix computes a global scalar which can be accessed by various output commands. The scalar is the potential energy discussed above. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

**Note:** If you want the potential energy associated with the CMAP terms forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

---

**18.26. fix cmap command**
18.26.5 Restrictions

To function as expected this fix command must be issued before a read_data command but after a read_restart command.

This fix can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

18.27 fix colvars command

18.27.1 Syntax

fix ID group-ID colvars configfile keyword values ...

- ID, group-ID are documented in fix command
- colvars = style name of this fix command
- configfile = the configuration file for the colvars module
- keyword = input or output or seed or tstat
  - input arg = colvars.state file name or prefix or NULL (default: NULL)
  - output arg = output filename prefix (default: out)
  - seed arg = seed for random number generator (default: 1966)
  - unwrap arg = yes or no
    - use unwrapped coordinates in collective variables (default: yes)
  - tstat arg = fix id of a thermostat or NULL (default: NULL)

18.27.2 Examples

fix mtd all colvars peptide.colvars.inp seed 2122 input peptide.colvars.state output peptide
fix abf all colvars colvars.inp tstat 1

18.27.3 Description

This fix interfaces LAMMPS to the collective variables “Colvars” library, which allows to calculate potentials of mean force (PMFs) for any set of colvars, using different sampling methods: currently implemented are the Adaptive Biasing Force (ABF) method, metadynamics, Steered Molecular Dynamics (SMD) and Umbrella Sampling (US) via a flexible harmonic restraint bias.

This documentation describes only the fix colvars command itself and LAMMPS specific parts of the code. The full documentation of the colvars library is available as this supplementary PDF document

The Colvars library is developed at https://github.com/colvars/colvars A detailed discussion of its implementation is in (Fiorin).

There are some example scripts for using this package with LAMMPS in the examples/USER/colvars directory.

The only mandatory argument to the fix is the filename to the colvars input file that contains the input that is independent from the MD program in which the colvars library has been integrated.

The group-ID entry is ignored. The collective variable module will always apply to the entire system and there can only be one instance of the colvars fix at a time. The colvars fix will only communicate the minimum information necessary and the colvars library supports multiple, completely independent collective variables, so there is no restriction to functionality by limiting the number of colvars fixes.

The input keyword allows to specify a state file that would contain the restart information required in order to continue a calculation from a prerecorded state. Fix colvars records it state in binary restart files, so when using the read_restart command, this is usually not needed.

The output keyword allows to specify the output prefix. All output files generated will use this prefix followed by the “.colvars.” and a word like “state” or “traj”.

The seed keyword contains the seed for the random number generator that will be used in the colvars module.

The unwrap keyword controls whether wrapped or unwrapped coordinates are passed to the colvars library for calculation of the collective variables and the resulting forces. The default is yes, i.e. to use the image flags to reconstruct the absolute atom positions. Setting this to no will use the current local coordinates that are wrapped back into the simulation cell at each re-neighboring instead.

The tstat keyword can be either NULL or the label of a thermostatting fix that thermostats all atoms in the fix colvars group. This will be used to provide the colvars module with the current thermostat target temperature.

18.27.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the current status of the colvars module into binary restart files. This is in addition to the text mode status file that is written by the colvars module itself and the kind of information in both files is identical.

The fix_modify energy option is supported by this fix to add the energy change from the biasing force added by the fix to the system’s potential energy as part of thermodynamic output.

The fix_modify configfile <config file> option allows to add settings from an additional config file to the colvars module. This option can only be used, after the system has been initialized with a run command.

The fix_modify config <quoted string> option allows to add settings from inline strings. Those have to fit on a single line when enclosed in a pair of double quotes (“”), or can span multiple lines when bracketed by a pair of triple double quotes ("""), like python embedded documentation).

This fix computes a global scalar which can be accessed by various output commands. The scalar is the cumulative energy change due to this fix. The scalar value calculated by this fix is “extensive”.

18.27. fix colvars command
18.27.5 Restrictions

This fix is part of the USER-COLVARS package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

There can only be one colvars fix active at a time. Since the interface communicates only the minimum amount of information and colvars module itself can handle an arbitrary number of collective variables, this is not a limitation of functionality.

18.28 fix controller command

18.28.1 Syntax

fix ID group-ID controller Nevery alpha Kp Ki Kd pvar setpoint cvar

- ID, group-ID are documented in fix command
- controller = style name of this fix command
- Nevery = invoke controller every this many timesteps
- alpha = coupling constant for PID equation (see units discussion below)
- Kp = proportional gain in PID equation (unitless)
- Ki = integral gain in PID equation (unitless)
- Kd = derivative gain in PID equation (unitless)
- pvar = process variable of form c_ID, c_ID[I], f_ID, f_ID[I], or v_name
  - c_ID = global scalar calculated by a compute with ID
  - c_ID[I] = Ith component of global vector calculated by a compute with ID
  - f_ID = global scalar calculated by a fix with ID
  - f_ID[I] = Ith component of global vector calculated by a fix with ID
  - v_name = value calculated by an equal-style variable with name
- setpoint = desired value of process variable (same units as process variable)
- cvar = name of control variable
18.28.2 Examples

```
fix 1 all controller 100 1.0 0.5 0.0 0.0 c_thermo_temp 1.5 tcontrol
fix 1 all controller 100 0.2 0.5 0 100.0 v_pxxwall 1.01325 xwall
fix 1 all controller 10000 0.2 0.5 0 2000 v_avpe -3.785 tcontrol
```

18.28.3 Description

This fix enables control of a LAMMPS simulation using a control loop feedback mechanism known as a proportional-integral-derivative (PID) controller. The basic idea is to define a "process variable" which is a quantity that can be monitored during a running simulation. A desired target value is chosen for the process variable. A "control variable" is also defined which is an adjustable attribute of the running simulation, which the process variable will respond to. The PID controller continuously adjusts the control variable based on the difference between the process variable and the target.

Here are examples of ways in which this fix can be used. The examples/pid directory contains a script that implements the simple thermostat.

<table>
<thead>
<tr>
<th>Goal</th>
<th>process variable</th>
<th>control variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simple thermostat</td>
<td>instantaneous T</td>
<td>thermostat target T</td>
</tr>
<tr>
<td>Find melting temperature</td>
<td>average PE per atom</td>
<td>thermostat target T</td>
</tr>
<tr>
<td>Control pressure in non-periodic system</td>
<td>force on wall</td>
<td>position of wall</td>
</tr>
</tbody>
</table>

Note: For this fix to work, the control variable must actually induce a change in a running LAMMPS simulation. Typically this will only occur if there is some other command (e.g. a thermostat fix) which uses the control variable as an input parameter. This could be done directly or indirectly, e.g. the other command uses a variable as input whose formula uses the control variable. The other command should alter its behavior dynamically as the variable changes.

Note: If there is a command you think could be used in this fashion, but does not currently allow a variable as an input parameter, please notify the LAMMPS developers. It is often not difficult to enable a command to use a variable as an input parameter.

The group specified with this command is ignored. However, note that the process variable may be defined by calculations performed by computes and fixes which store their own "group" definitions.

The PID controller is invoked once each \texttt{Nevery} timesteps.

The PID controller is implemented as a discretized version of the following dynamic equation:

\[
\frac{dc}{dt} = \dot{E} - \alpha (K_p e + K_i \int_0^t e \, dt + K_d \frac{dc}{dt})
\]

where \(c\) is the continuous time analog of the control variable, \(e = \text{pvar-setpoint}\) is the error in the process variable, and \(\alpha, K_p, K_i,\) and \(K_d\) are constants set by the corresponding keywords described above. The discretized version of this equation is:

\[
c_n = \dot{E} c_{n-1} - \alpha \left( K_p \tau e_n + K_i \tau^2 \sum_{i=1}^{n} e_i + K_d (e_n - e_{n-1}) \right)
\]

where \(\tau = \text{Nevery} \cdot \text{timestep}\) is the time interval between updates, and the subscripted variables indicate the values of \(c\) and \(e\) at successive updates.
From the first equation, it is clear that if the three gain values $K_p$, $K_i$, $K_d$ are dimensionless constants, then $\alpha$ must have units of [unit $cvar$]/[unit $pvar$]/[unit time] e.g. [eV/K/ps]. The advantage of this unit scheme is that the value of the constants should be invariant under a change of either the MD timestep size or the value of $Nevery$. Similarly, if the LAMMPS unit style is changed, it should only be necessary to change the value of $\alpha$ to reflect this, while leaving $K_p$, $K_i$, and $K_d$ unaltered.

When choosing the values of the four constants, it is best to first pick a value and sign for $\alpha$ that is consistent with the magnitudes and signs of $pvar$ and $cvar$. The magnitude of $K_p$ should then be tested over a large positive range keeping $K_i = K_d = 0$. A good value for $K_p$ will produce a fast response in $pvar$, without overshooting the setpoint. For many applications, proportional feedback is sufficient, and so $K_i = K_d = 0$ can be used. In cases where there is a substantial lag time in the response of $pvar$ to a change in $cvar$, this can be counteracted by increasing $K_d$. In situations where $pvar$ plateaus without reaching setpoint, this can be counteracted by increasing $K_i$. In the language of Charles Dickens, $K_p$ represents the error of the present, $K_i$ the error of the past, and $K_d$ the error yet to come.

Because this fix updates $cvar$, but does not initialize its value, the initial value is that assigned by the user in the input script via the internal-style variable command. This value is used (by the other LAMMPS command that used the variable) until this fix performs its first update of $cvar$ after $Nevery$ timesteps. On the first update, the value of the derivative term is set to zero, because the value of $e_{n-1}$ is not yet defined.

The process variable $pvar$ can be specified as the output of a compute or fix or the evaluation of a variable. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity.

If $pvar$ begins with “c_”, a compute ID must follow which has been previously defined in the input script and which generates a global scalar or vector. See the individual compute doc page for details. If no bracketed integer is appended, the scalar calculated by the compute is used. If a bracketed integer is appended, the Ith value of the vector calculated by the compute is used. Users can also write code for their own compute styles and add them to LAMMPS.

If $pvar$ begins with “f_”, a fix ID must follow which has been previously defined in the input script and which generates a global scalar or vector. See the individual fix doc page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when fix controller references the values, or else an error results. If no bracketed integer is appended, the scalar calculated by the fix is used. If a bracketed integer is appended, the Ith value of the vector calculated by the fix is used. Users can also write code for their own fix style and add them to LAMMPS.

If $pvar$ begins with “v_”, a variable name must follow which has been previously defined in the input script. Only equal-style variables can be referenced. See the variable command for details. Note that variables of style equal define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying the process variable.

The target value setpoint for the process variable must be a numeric value, in whatever units $pvar$ is defined for.

The control variable $cvar$ must be the name of an internal-style variable previously defined in the input script. Note that it is not specified with a “v_” prefix, just the name of the variable. It must be an internal-style variable, because this fix updates its value directly. Note that other commands can use an equal-style versus internal-style variable interchangeably.
18.28.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix produces a global vector with 3 values which can be accessed by various output commands. The values can be accessed on any timestep, though they are only updated on timesteps that are a multiple of Nevery.

The three values are the most recent updates made to the control variable by each of the 3 terms in the PID equation above. The first value is the proportional term, the second is the integral term, the third is the derivative term.

The units of the vector values will be whatever units the control variable is in. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

```

18.29.3 Description

Change the volume and/or shape of the simulation box during a dynamics run. Orthogonal simulation boxes have 3 adjustable parameters (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable parameters (x,y,z,xy,xz,yz). Any or all of them can be adjusted independently and simultaneously by this command.

This fix can be used to perform non-equilibrium MD (NEMD) simulations of a continuously strained system. See the `fix nvt/sllod` and `compute temp/deform` commands for more details. Note that simulation of a continuously extended system (extensional flow) can be modeled using the `USER-UEF package` and its `fix commands`.

For the x, y, z parameters, the associated dimension cannot be shrink-wrapped. For the xy, yz, xz parameters, the associated second dimension cannot be shrink-wrapped. Dimensions not varied by this command can be periodic or non-periodic. Dimensions corresponding to unspecified parameters can also be controlled by a `fix npt` or `fix nph` command.

The size and shape of the simulation box at the beginning of the simulation run were either specified by the `create_box` or `read_data` or `read_restart` command used to setup the simulation initially if it is the first run, or they are the values from the end of the previous run. The `create_box`, `read_data`, and `read_restart` commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors. If fix deform changes the xy,xz,yz tilt factors, then the simulation box must be triclinic, even if its initial tilt factors are 0.0.

As described below, the desired simulation box size and shape at the end of the run are determined by the parameters of the fix deform command. Every Nth timestep during the run, the simulation box is expanded, contracted, or tilted to ramped values between the initial and final values.

For the x, y, and z parameters, this is the meaning of their styles and values.

The `final`, `delta`, `scale`, `vel`, and `erate` styles all change the specified dimension of the box via “constant displacement” which is effectively a “constant engineering strain rate”. This means the box dimension changes linearly with time from its initial to final value.

For style `final`, the final lo and hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style `delta`, plus or minus changes in the lo/hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style `scale`, a multiplicative factor to apply to the box length of a dimension is specified. For example, if the initial box length is 10, and the factor is 1.1, then the final box length will be 11. A factor less than 1.0 means compression.

For style `vel`, a velocity at which the box length changes is specified in units of distance/time. This is effectively a “constant engineering strain rate”, where rate = V/L0 and L0 is the initial box length. The distance can be in lattice or box distance units. See the discussion of the units keyword below. For example, if the initial box length is 100 Angstroms, and V is 10 Angstroms/ps, then after 10 ps, the box length will have doubled. After 20 ps, it will have tripled.

The `erate` style changes a dimension of the box at a “constant engineering strain rate”. The units of the specified strain rate are 1/time. See the `units` command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units). Tensile strain is unitless and is defined as delta/L0, where L0 is the original box length and delta is the change relative to the original length. The box length L as a function of time will change as
L(t) = L(0) (1 + erate*dt)

where dt is the elapsed time (in time units). Thus if erate R is specified as 0.1 and time units are picoseconds, this means the box length will increase by 10% of its original length every picosecond. I.e. strain after 1 ps = 0.1, strain after 2 ps = 0.2, etc. R = -0.01 means the box length will shrink by 1% of its original length every picosecond. Note that for an “engineering” rate the change is based on the original box length, so running with R = 1 for 10 picoseconds expands the box length by a factor of 11 (strain of 10), which is different that what the trate style would induce.

The trate style changes a dimension of the box at a “constant true strain rate”. Note that this is not an “engineering strain rate”, as the other styles are. Rather, for a “true” rate, the rate of change is constant, which means the box dimension changes non-linearly with time from its initial to final value. The units of the specified strain rate are 1/time. See the units command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units). Tensile strain is unitless and is defined as delta/L0, where L0 is the original box length and delta is the change relative to the original length.

The box length L as a function of time will change as

L(t) = L0 exp(trate*dt)

where dt is the elapsed time (in time units). Thus if trate R is specified as ln(1.1) and time units are picoseconds, this means the box length will increase by 10% of its current (not original) length every picosecond. I.e. strain after 1 ps = 0.1, strain after 2 ps = 0.21, etc. R = ln(2) or ln(3) means the box length will double or triple every picosecond. R = ln(0.99) means the box length will shrink by 1% of its current length every picosecond. Note that for a “true” rate the change is continuous and based on the current length, so running with R = ln(2) for 10 picoseconds does not expand the box length by a factor of 11 as it would with erate, but by a factor of 1024 since the box length will double every picosecond.

Note that to change the volume (or cross-sectional area) of the simulation box at a constant rate, you can change multiple dimensions via erate or trate. E.g. to double the box volume in a picosecond picosecond, you could set “x erate M”, “y erate M”, “z erate M”, with M = pow(2,1/3) - 1 = 0.26, since if each box dimension grows by 26%, the box volume doubles. Or you could set “x trate M”, “y trate M”, “z trate M”, with M = ln(1.26) = 0.231, and the box volume would double every picosecond.

The volume style changes the specified dimension in such a way that the box volume remains constant while other box dimensions are changed explicitly via the styles discussed above. For example, “x scale 1.1 y scale 1.1 z volume” will shrink the z box length as the x,y box lengths increase, to keep the volume constant (product of x,y,z lengths). If “x scale 1.1 z volume” is specified and parameter y is unspecified, then the z box length will shrink as x increases to keep the product of x,z lengths constant. If “x scale 1.1 y volume z volume” is specified, then both the y,z box lengths will shrink as x increases to keep the volume constant (product of x,y,z lengths). In this case, the y,z box lengths shrink so as to keep their relative aspect ratio constant.

For solids or liquids, note that when one dimension of the box is expanded via fix deform (i.e. tensile strain), it may be physically undesirable to hold the other 2 box lengths constant (unspecified by fix deform) since that implies a density change. Using the volume style for those 2 dimensions to keep the box volume constant may make more physical sense, but may also not be correct for materials and potentials whose Poisson ratio is not 0.5. An alternative is to use fix npt aniso with zero applied pressure on those 2 dimensions, so that they respond to the tensile strain dynamically.

The wiggle style oscillates the specified box length dimension sinusoidally with the specified amplitude and period. I.e. the box length L as a function of time is given by

L(t) = L0 + A sin(2*pi t/Tp)

where L0 is its initial length. If the amplitude A is a positive number the box initially expands, then contracts, etc. If A is negative then the box initially contracts, then expands, etc. The amplitude can be in lattice or box distance units. See the discussion of the units keyword below.

The variable style changes the specified box length dimension by evaluating a variable, which presumably is a function of time. The variable with name1 must be an equal-style variable and should calculate a change in box length in units of distance. Note that this distance is in box units, not lattice units; see the discussion of the units keyword below. The formula associated with variable name1 can reference the current timestep. Note that it should return the “change” in
box length, not the absolute box length. This means it should evaluate to 0.0 when invoked on the initial timestep of the run following the definition of fix deform. It should evaluate to a value > 0.0 to dilate the box at future times, or a value < 0.0 to compress the box.

The variable name2 must also be an equal-style variable and should calculate the rate of box length change, in units of distance/time, i.e. the time-derivative of the name1 variable. This quantity is used internally by LAMMPS to reset atom velocities when they cross periodic boundaries. It is computed internally for the other styles, but you must provide it when using an arbitrary variable.

Here is an example of using the variable style to perform the same box deformation as the wiggle style formula listed above, where we assume that the current timestep = 0.

```
variable A equal 5.0
variable Tp equal 10.0
variable displace equal "v_A * sin(2*PI * step*dt/v_Tp)"
variable rate equal "2*PI*v_A/v_Tp * cos(2*PI * step*dt/v_Tp)"
fix 2 all deform 1 x variable v_displace v_rate remap v
```

For the scale, vel, erate, trate, volume, wiggle, and variable styles, the box length is expanded or compressed around its mid point.

For the xy, xz, and yz parameters, this is the meaning of their styles and values. Note that changing the tilt factors of a triclinic box does not change its volume.

The final, delta, vel, and erate styles all change the shear strain at a “constant engineering shear strain rate”. This means the tilt factor changes linearly with time from its initial to final value.

For style final, the final tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the units keyword below.

For style delta, a plus or minus change in the tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the units keyword below.

For style vel, a velocity at which the tilt factor changes is specified in units of distance/time. This is effectively an “engineering shear strain rate”, where rate = V/L0 and L0 is the initial box length perpendicular to the direction of shear. The distance can be in lattice or box distance units. See the discussion of the units keyword below. For example, if the initial tilt factor is 5 Angstroms, and the V is 10 Angstroms/ps, then after 1 ps, the tilt factor will be 15 Angstroms. After 2 ps, it will be 25 Angstroms.

The erate style changes a tilt factor at a “constant engineering shear strain rate”. The units of the specified shear strain rate are 1/time. See the units command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units). Shear strain is unitless and is defined as offset/length, where length is the box length perpendicular to the shear direction (e.g. y box length for xy deformation) and offset is the displacement distance in the shear direction (e.g. x direction for xy deformation) from the unstrained orientation.

The tilt factor T as a function of time will change as

\[ T(t) = T_0 + L_0 \times \text{erate} \times dt \]

where T0 is the initial tilt factor, L0 is the original length of the box perpendicular to the shear direction (e.g. y box length for xy deformation), and dt is the elapsed time (in time units). Thus if erate R is specified as 0.1 and time units are picoseconds, this means the shear strain will increase by 0.1 every picosecond. I.e. if the xy shear strain was initially 0.0, then strain after 1 ps = 0.1, strain after 2 ps = 0.2, etc. Thus the tilt factor would be 0.0 at time 0, 0.1*xybox at 1 ps, 0.2*xybox at 2 ps, etc, where xybox is the original y box length. R = 1 or 2 means the tilt factor will increase by 1 or 2 every picosecond. R = -0.01 means a decrease in shear strain by 0.01 every picosecond.

The trate style changes a tilt factor at a “constant true shear strain rate”. Note that this is not an “engineering shear strain rate”, as the other styles are. Rather, for a “true” rate, the rate of change is constant, which means the tilt factor changes non-linearly with time from its initial to final value. The units of the specified shear strain rate are 1/time.

18.29. fix deform command
See the `units` command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units. Shear strain is unitless and is defined as offset/length, where length is the box length perpendicular to the shear direction (e.g. y box length for xy deformation) and offset is the displacement distance in the shear direction (e.g. x direction for xy deformation) from the unstrained orientation.

The tilt factor $T$ as a function of time will change as

$$T(t) = T_0 \exp(trate*dt)$$

where $T_0$ is the initial tilt factor and $dt$ is the elapsed time (in time units). Thus if $trate$ $R$ is specified as $\ln(1.1)$ and time units are picoseconds, this means the shear strain or tilt factor will increase by 10% every picosecond. I.e. if the xy shear strain was initially 0.1, then strain after 1 ps = 0.11, strain after 2 ps = 0.121, etc. $R = \ln(2)$ or $\ln(3)$ means the tilt factor will double or triple every picosecond. $R = \ln(0.99)$ means the tilt factor will shrink by 1% every picosecond. Note that the change is continuous, so running with $R = \ln(2)$ for 10 picoseconds does not change the tilt factor by a factor of 10, but by a factor of 1024 since it doubles every picosecond. Note that the initial tilt factor must be non-zero to use the $trate$ option.

Note that shear strain is defined as the tilt factor divided by the perpendicular box length. The $erate$ and $trate$ styles control the tilt factor, but assume the perpendicular box length remains constant. If this is not the case (e.g. it changes due to another fix deform parameter), then this effect on the shear strain is ignored.

The `wiggle` style oscillates the specified tilt factor sinusoidally with the specified amplitude and period. I.e. the tilt factor $T$ as a function of time is given by

$$T(t) = T_0 + A \sin(2\pi t/Tp)$$

where $T_0$ is its initial value. If the amplitude $A$ is a positive number the tilt factor initially becomes more positive, then more negative, etc. If $A$ is negative then the tilt factor initially becomes more negative, then more positive, etc. The amplitude can be in lattice or box distance units. See the discussion of the units keyword below.

The `variable` style changes the specified tilt factor by evaluating a variable, which presumably is a function of time. The variable with $name1$ must be an equal-style variable and should calculate a change in tilt in units of distance. Note that this distance is in box units, not lattice units; see the discussion of the units keyword below. The formula associated with variable $name1$ can reference the current timestep. Note that it should return the “change” in tilt factor, not the absolute tilt factor. This means it should evaluate to 0.0 when invoked on the initial timestep of the run following the definition of fix deform.

The variable $name2$ must also be an equal-style variable and should calculate the rate of tilt change, in units of distance/time, i.e. the time-derivative of the $name1$ variable. This quantity is used internally by LAMMPS to reset atom velocities when they cross periodic boundaries. It is computed internally for the other styles, but you must provide it when using an arbitrary variable.

Here is an example of using the `variable` style to perform the same box deformation as the `wiggle` style formula listed above, where we assume that the current timestep = 0.

```plaintext
variable A equal 5.0
variable Tp equal 10.0
variable displace equal "v_A * sin(2*PI * step*dt/v_Tp)"
variable rate equal "2*PI*v_A/v_Tp * cos(2*PI * step*dt/v_Tp)"
fix 2 all deform 1 xy variable v_displace v_rate remap v
```

All of the tilt styles change the xy, xz, yz tilt factors during a simulation. In LAMMPS, tilt factors (xy,xz,yz) for triclinic boxes are normally bounded by half the distance of the parallel box length. See the discussion of the `flip` keyword below, to allow this bound to be exceeded, if desired.

For example, if xlo = 2 and xhi = 12, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between -(xhi-xlo)/2 and +(yhi-ylo)/2. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all equivalent.
To obey this constraint and allow for large shear deformations to be applied via the $xy$, $xz$, or $yz$ parameters, the following algorithm is used. If $prd$ is the associated parallel box length (10 in the example above), then if the tilt factor exceeds the accepted range of -5 to 5 during the simulation, then the box is flipped to the other limit (an equivalent box) and the simulation continues. Thus for this example, if the initial $xy$ tilt factor was 0.0 and “$xy$ final 100.0” was specified, then during the simulation the $xy$ tilt factor would increase from 0.0 to 5.0, the box would be flipped so that the tilt factor becomes -5.0, the tilt factor would increase from -5.0 to 5.0, the box would be flipped again, etc. The flip occurs 10 times and the final tilt factor at the end of the simulation would be 0.0. During each flip event, atoms are remapped into the new box in the appropriate manner.

The one exception to this rule is if the first dimension in the tilt factor (x for $xy$) is non-periodic. In that case, the limits on the tilt factor are not enforced, since flipping the box in that dimension does not change the atom positions due to non-periodicity. In this mode, if you tilt the system to extreme angles, the simulation will simply become inefficient due to the highly skewed simulation box.

Each time the box size or shape is changed, the remap keyword determines whether atom positions are remapped to the new box. If remap is set to $x$ (the default), atoms in the fix group are remapped; otherwise they are not. Note that their velocities are not changed, just their positions are altered. If remap is set to $v$, then any atom in the fix group that crosses a periodic boundary will have a delta added to its velocity equal to the difference in velocities between the lo and hi boundaries. Note that this velocity difference can include tilt components, e.g. a delta in the $x$ velocity when an atom crosses the $y$ periodic boundary. If remap is set to none, then neither of these remappings take place.

Conceptually, setting remap to $x$ forces the atoms to deform via an affine transformation that exactly matches the box deformation. This setting is typically appropriate for solids. Note that though the atoms are effectively “moving” with the box over time, it is not due to their having a velocity that tracks the box change, but only due to the remapping. By contrast, setting remap to $v$ is typically appropriate for fluids, where you want the atoms to respond to the change in box size/shape on their own and acquire a velocity that matches the box change, so that their motion will naturally track the box without explicit remapping of their coordinates.

**Note:** When non-equilibrium MD (NEMD) simulations are performed using this fix, the option “remap $v$” should normally be used. This is because fix nvt/sllod adjusts the atom positions and velocities to induce a velocity profile that matches the changing box size/shape. Thus atom coordinates should NOT be remapped by fix deform, but velocities SHOULD be when atoms cross periodic boundaries, since that is consistent with maintaining the velocity profile already created by fix nvt/sllod. LAMMPS will warn you if the remap setting is not consistent with fix nvt/sllod.

**Note:** For non-equilibrium MD (NEMD) simulations using “remap $v$” it is usually desirable that the fluid (or flowing material, e.g. granular particles) stream with a velocity profile consistent with the deforming box. As mentioned above, using a thermostat such as fix nvt/sllod or fix lavgevin (with a bias provided by compute temp/deform), will typically accomplish that. If you do not use a thermostat, then there is no driving force pushing the atoms to flow in a manner consistent with the deforming box. E.g. for a shearing system the box deformation velocity may vary from 0 at the bottom to 10 at the top of the box. But the stream velocity profile of the atoms may vary from -5 at the bottom to +5 at the top. You can monitor these effects using the fix ave/chunk, compute temp/deform, and compute temp/profile commands. One way to induce atoms to stream consistent with the box deformation is to give them an initial velocity profile, via the velocity ramp command, that matches the box deformation rate. This also typically helps the system come to equilibrium more quickly, even if a thermostat is used.

**Note:** If a fix rigid is defined for rigid bodies, and remap is set to $x$, then the center-of-mass coordinates of rigid bodies will be remapped to the changing simulation box. This will be done regardless of whether atoms in the rigid bodies are in the fix deform group or not. The velocity of the centers of mass are not remapped even if remap is set to $v$, since fix nvt/sllod does not currently do anything special for rigid particles. If you wish to perform a NEMD simulation of
rigid particles, you can either thermostat them independently or include a background fluid and thermostat the fluid via fix nvt/sllod.

The flip keyword allows the tilt factors for a triclinic box to exceed half the distance of the parallel box length, as discussed above. If the flip value is set to yes, the bound is enforced by flipping the box when it is exceeded. If the flip value is set to no, the tilt will continue to change without flipping. Note that if you apply large deformations, this means the box shape can tilt dramatically LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor’s irregular-shaped sub-domain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

The units keyword determines the meaning of the distance units used to define various arguments. A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacing. Note that the units choice also affects the vel style parameters since it is defined in terms of distance/time. Also note that the units keyword does not affect the variable style. You should use the xlat, ylat, zlat keywords of the thermo_style command if you want to include lattice spacings in a variable formula.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

**18.29.4 Restart, fix_modify, output, run start/stop, minimize info**

This fix will restore the initial box settings from binary restart files, which allows the fix to be properly continue deformation, when using the start/stop options of the run command. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands.

This fix can perform deformation over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

**18.29.5 Restrictions**

You cannot apply x, y, or z deformations to a dimension that is shrink-wrapped via the boundary command.

You cannot apply xy, yz, or xz deformations to a second dimension (y in xy) that is shrink-wrapped via the boundary command.
18.29.6 Related commands

*change_box*

18.29.7 Default

The option defaults are remap = x, flip = yes, and units = lattice.

18.30 fix deposit command

18.30.1 Syntax

```
fix ID group-ID deposit N type M seed keyword values ...
```

- ID, group-ID are documented in *fix* command
- deposit = style name of this fix command
- N = # of atoms or molecules to insert
- type = atom type to assign to inserted atoms (offset for molecule insertion)
- M = insert a single atom or molecule every M steps
- seed = random # seed (positive integer)
- one or more keyword/value pairs may be appended to args
- keyword = region or id or global or local or near or gaussian or attempt or rate or vx or vy or vz or mol or rigid or shake or units

  - region value = region-ID
  - region-ID = ID of region to use as insertion volume
  - id value = max or next
    - max = atom ID for new atom(s) is max ID of all current atoms plus one
    - next = atom ID for new atom(s) increments by one for every deposition
  - global value = lo hi
    - lo,hi = put new atom/molecule a distance lo-hi above all other atoms
  - local value = lo hi delta
    - lo,hi = put new atom/molecule a distance lo-hi above any nearby atom
    - delta = lateral distance within which a neighbor is considered "nearby"
  - near value = R
    - R = only insert atom/molecule if further than R from existing particles
  - gaussian value = xmid ymid zmid sigma
    - xmid,ymid,zmid = center of the gaussian distribution (distance units)
    - sigma = width of gaussian distribution (distance units)
  - attempt value = Q
    - Q = attempt a single insertion up to Q times
  - rate value = V
    - V = z velocity (y in 2d) at which insertion volume moves (velocity units)
vx values = vxlo vxhi
    vxlo,vxhi = range of x velocities for inserted atom/molecule (velocity units)
vy values = vylo vyhi
    vylo,vyhi = range of y velocities for inserted atom/molecule (velocity units)
vz values = vzlo vzhi
    vzlo,vzhi = range of z velocities for inserted atom/molecule (velocity units)
target values = tx ty tz
    tx,ty,tz = location of target point (distance units)
mol value = template-ID
    template-ID = ID of molecule template specified in a separate molecule command
molfrac values = f1 f2 ... fN
    f1 to fN = relative probability of creating each of N molecules in template-ID
rigid value = fix-ID
    fix-ID = ID of fix rigid/small command
shake value = fix-ID
    fix-ID = ID of fix shake command
orient values = rx ry rz
    rx,ry,rz = vector to randomly rotate an inserted molecule around units value = lattice or box
    lattice = the geometry is defined in lattice units
    box = the geometry is defined in simulation box units

18.30.2 Examples

fix 5 insert deposit 200 2 100 777 region disk gaussian 5.0 5.0 9.0 1.0 units box

18.30.3 Description

Insert a single atom or molecule into the simulation domain every M timesteps until N atoms or molecules have been inserted. This is useful for simulating deposition onto a surface. For the remainder of this doc page, a single inserted atom or molecule is referred to as a “particle”.

If inserted particles are individual atoms, they are assigned the specified atom type. If they are molecules, the type of each atom in the inserted molecule is specified in the file read by the molecule command, and those values are added to the specified atom type. E.g. if the file specifies atom types 1,2,3, and those are the atom types you want for inserted molecules, then specify type = 0. If you specify type = 2, the in the inserted molecule will have atom types 3,4,5.

All atoms in the inserted particle are assigned to two groups: the default group “all” and the group specified in the fix deposit command (which can also be “all”).

If you are computing temperature values which include inserted particles, you will want to use the compute_modify dynamic option, which insures the current number of atoms is used as a normalizing factor each time the temperature is computed.
Care must be taken that inserted particles are not too near existing atoms, using the options described below. When inserting particles above a surface in a non-periodic box (see the boundary command), the possibility of a particle escaping the surface and flying upward should be considered, since the particle may be lost or the box size may grow infinitely large. A fix wall/reflect command can be used to prevent this behavior. Note that if a shrink-wrap boundary is used, it is OK to insert the new particle outside the box, however the box will immediately be expanded to include the new particle. When simulating a sputtering experiment it is probably more realistic to ignore those atoms using the thermo_modify command with the lost ignore option and a fixed boundary.

The fix deposit command must use the region keyword to define an insertion volume. The specified region must have been previously defined with a region command. It must be defined with side = in.

**Note:** LAMMPS checks that the specified region is wholly inside the simulation box. It can do this correctly for orthonormal simulation boxes. However for triclinic boxes, it only tests against the larger orthonormal box that bounds the tilted simulation box. If the specified region includes volume outside the tilted box, then an insertion will likely fail, leading to a “lost atoms” error. Thus for triclinic boxes you should insure the specified region is wholly inside the simulation box.

The locations of inserted particles are taken from uniform distributed random numbers, unless the gaussian keyword is used. Then the individual coordinates are taken from a gaussian distribution of width sigma centered on xmid,ymid,zmid.

Individual atoms are inserted, unless the mol keyword is used. It specifies a template-ID previously defined using the molecule command, which reads files that define one or more molecules. The coordinates, atom types, charges, etc, as well as any bond/angle/etc and special neighbor information for the molecule can be specified in the molecule file. See the molecule command for details. The only settings required to be in each file are the coordinates and types of atoms in the molecule.

If the molecule template contains more than one molecule, the relative probability of depositing each molecule can be specified by the molfrac keyword. N relative probabilities, each from 0.0 to 1.0, are specified, where N is the number of molecules in the template. Each time a molecule is deposited, a random number is used to sample from the list of relative probabilities. The N values must sum to 1.0.

If you wish to insert molecules via the mol keyword, that will be treated as rigid bodies, use the rigid keyword, specifying as its value the ID of a separate fix rigid/small command which also appears in your input script.

**Note:** If you wish the new rigid molecules (and other rigid molecules) to be thermostatted correctly via fix rigid/small/nvt or fix rigid/small/npt, then you need to use the “fix_modify dynamic/dof yes” command for the rigid fix. This is to inform that fix that the molecule count will vary dynamically.

If you wish to insert molecules via the mol keyword, that will have their bonds or angles constrained via SHAKE, use the shake keyword, specifying as its value the ID of a separate fix shake command which also appears in your input script.

Each timestep a particle is inserted, the coordinates for its atoms are chosen as follows. For insertion of individual atoms, the “position” referred to in the following description is the coordinate of the atom. For insertion of molecule, the “position” is the geometric center of the molecule; see the molecule doc page for details. A random rotation of the molecule around its center point is performed, which determines the coordinates all the individual atoms.

A random position within the region insertion volume is generated. If neither the global or local keyword is used, the random position is the trial position. If the global keyword is used, the random x,y values are used, but the z position of the new particle is set above the highest current atom in the simulation by a distance randomly chosen between lo/hi. (For a 2d simulation, this is done for the y position.) If the local keyword is used, the z position is set a distance between lo/hi above the highest current atom in the simulation that is “nearby” the chosen x,y position. In this context, “nearby” means the lateral distance (in x,y) between the new and old particles is less than the delta setting.
Once a trial x,y,z position has been selected, the insertion is only performed if no current atom in the simulation is within a distance R of any atom in the new particle, including the effect of periodic boundary conditions if applicable. R is defined by the near keyword. Note that the default value for R is 0.0, which will allow atoms to strongly overlap if you are inserting where other atoms are present. This distance test is performed independently for each atom in an inserted molecule, based on the randomly rotated configuration of the molecule. If this test fails, a new random position within the insertion volume is chosen and another trial is made. Up to Q attempts are made. If the particle is not successfully inserted, LAMMPS prints a warning message.

**Note:** If you are inserting finite size particles or a molecule or rigid body consisting of finite-size particles, then you should typically set R larger than the distance at which any inserted particle may overlap with either a previously inserted particle or an existing particle. LAMMPS will issue a warning if R is smaller than this value, based on the radii of existing and inserted particles.

The rate option moves the insertion volume in the z direction (3d) or y direction (2d). This enables particles to be inserted from a successively higher height over time. Note that this parameter is ignored if the global or local keywords are used, since those options choose a z-coordinate for insertion independently.

The vx, vy, and vz components of velocity for the inserted particle are set using the values specified for the vx, vy, and vz keywords. Note that normally, new particles should be assigned a negative vertical velocity so that they move towards the surface. For molecules, the same velocity is given to every particle (no rotation or bond vibration).

If the target option is used, the velocity vector of the inserted particle is changed so that it points from the insertion position towards the specified target point. The magnitude of the velocity is unchanged. This can be useful, for example, for simulating a sputtering process. E.g. the target point can be far away, so that all incident particles strike the surface as if they are in an incident beam of particles at a prescribed angle.

The orient keyword is only used when molecules are deposited. By default, each molecule is inserted at a random orientation. If this keyword is specified, then (rx,ry,rz) is used as an orientation vector, and each inserted molecule is rotated around that vector with a random value from zero to 2*PI. For a 2d simulation, rx = ry = 0.0 is required, since rotations can only be performed around the z axis.

The id keyword determines how atom IDs and molecule IDs are assigned to newly deposited particles. Molecule IDs are only assigned if molecules are being inserted. For the max setting, the atom and molecule IDs of all current atoms are checked. Atoms in the new particle are assigned IDs starting with the current maximum plus one. If a molecule is inserted it is assigned an ID = current maximum plus one. This means that if particles leave the system, the new IDs may replace the lost ones. For the next setting, the maximum ID of any atom and molecule is stored at the time the fix is defined. Each time a new particle is added, this value is incremented to assign IDs to the new atom(s) or molecule. Thus atom and molecule IDs for deposited particles will be consecutive even if particles leave the system over time.

The units keyword determines the meaning of the distance units used for the other deposition parameters. A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacing. Note that the units choice affects all the keyword values that have units of distance or velocity.

**Note:** If you are monitoring the temperature of a system where the atom count is changing due to adding particles, you typically should use the compute modify dynamic yes command for the temperature compute you are using.
18.30.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the deposition to binary restart files. This includes information about how many particles have been deposited, the random number generator seed, the next timestep for deposition, etc. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** For this to work correctly, the timestep must **not** be changed after reading the restart with reset_timestep. The fix will try to detect it and stop with an error.

None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.30.5 Restrictions

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The specified insertion region cannot be a “dynamic” region, as defined by the region command.

18.30.6 Related commands

*fix pour, region*

18.30.7 Default

Insertions are performed for individual atoms, i.e. no mol setting is defined. If the mol keyword is used, the default for molfrac is an equal probabilities for all molecules in the template. Additional option defaults are id = max, delta = 0.0, near = 0.0, attempt = 10, rate = 0.0, vx = 0.0 0.0, vy = 0.0 0.0, vz = 0.0 0.0, and units = lattice.

18.31 fix dpd/energy command

Accelerator Variants: dpd/energy/kk

18.31.1 Syntax

```
fix ID group-ID dpd/energy
```

- ID, group-ID are documented in fix command
- dpd/energy = style name of this fix command
18.31.2 Examples

```
fix 1 all dpd/energy
```

18.31.3 Description

Perform constant energy dissipative particle dynamics (DPD-E) integration. This fix updates the internal energies for particles in the group at each timestep. It must be used in conjunction with a deterministic integrator (e.g., `fix nve`) that updates the particle positions and velocities.

For fix `dpd/energy`, the particle internal temperature is related to the particle internal energy through a mesoparticle equation of state. An additional fix must be specified that defines the equation of state for each particle, e.g., `fix eos/cv`.

This fix must be used with the `pair_style dpd/ft/energy` command.

Note that numerous variants of DPD can be specified by choosing an appropriate combination of the integrator and `pair_style dpd/ft/energy` command. DPD under isoenergetic conditions can be specified by using fix `dpd/energy`, fix `nve` and `pair_style dpd/ft/energy`. DPD under isoenthalpic conditions can be specified by using fix `dpd/energy`, fix `nph` and `pair_style dpd/ft/energy`. Examples of each DPD variant are provided in the examples/USER/dpd directory.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

18.31.4 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix must be used with an additional fix that specifies time integration, e.g., `fix nve`.

The fix `dpd/energy` requires the `dpd atom_style` to be used in order to properly account for the particle internal energies and temperature.

The fix `dpd/energy` must be used with an additional fix that specifies the mesoparticle equation of state for each particle.

18.32 fix edpd/source command

18.33 fix tdpd/source command

18.33.1 Syntax

```plaintext
fix ID group-ID edpd/source keyword values ...
fix ID group-ID tdpd/source cc_index keyword values ...
```

- ID, group-ID are documented in `fix` command
- edpd/source or tdpd/source = style name of this fix command
- index (only specified for tdpd/source) = index of chemical species (1 to Nspecies)
- keyword = sphere or cuboid

**sphere** values = cx,cy,cz,radius,source
  cx,cy,cz = x,y,z center of spherical domain (distance units)
  radius = radius of a spherical domain (distance units)
  source = heat source or concentration source (flux units, see below)

**cuboid** values = cx,cy,cz,dLx,dLy,dLz,source
  cx,cy,cz = x,y,z lower left corner of a cuboid domain (distance units)
  dLx,dLy,dLz = x,y,z side length of a cuboid domain (distance units)
  source = heat source or concentration source (flux units, see below)

18.33.2 Examples

```plaintext
fix 1 all edpd/source sphere 0.0 0.0 0.0 5.0 0.01
fix 1 all edpd/source cuboid 0.0 0.0 0.0 20.0 10.0 10.0 -0.01
fix 1 all tdpd/source 1 sphere 5.0 0.0 0.0 5.0 0.01
fix 1 all tdpd/source 2 cuboid 0.0 0.0 0.0 20.0 10.0 10.0 0.01
```
18.33.3 Description

Fix edpd/source adds a heat source as an external heat flux to each atom in a spherical or cuboid domain, where the source is in units of energy/time. Fix tdpd/source adds an external concentration source of the chemical species specified by index as an external concentration flux for each atom in a spherical or cuboid domain, where the source is in units of mole/volume/time.

This command can be used to give an additional heat/concentration source term to atoms in a simulation, such as for a simulation of a heat conduction with a source term (see Fig.12 in (Li2014)) or diffusion with a source term (see Fig.1 in (Li2015)), as an analog of a periodic Poiseuille flow problem.

If the sphere keyword is used, the cx,cy,cz,radius defines a spherical domain to apply the source flux to.

If the cuboid keyword is used, the cx,cy,cz,dLx,dLy,dLz defines a cuboid domain to apply the source flux to.

18.33.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.33.5 Restrictions

This fix is part of the USER-MESODPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Fix edpd/source must be used with the pair_style edpd command. Fix tdpd/source must be used with the pair_style tdpd command.

18.34 fix drag command

18.34.1 Syntax

```
fix ID group-ID drag x y z fmag delta
```

- ID, group-ID are documented in `fix` command
- `drag` = style name of this fix command
- `x,y,z` = coord to drag atoms towards
- `fmag` = magnitude of force to apply to each atom (force units)
- `delta` = cutoff distance inside of which force is not applied (distance units)

18.34.2 Examples

```
fix center small-molecule drag 0.0 10.0 0.0 5.0 2.0
```

18.34.3 Description

Apply a force to each atom in a group to drag it towards the point $(x,y,z)$. The magnitude of the force is specified by `fmag`. If an atom is closer than a distance `delta` to the point, then the force is not applied.

Any of the `x,y,z` values can be specified as NULL which means do not include that dimension in the distance calculation or force application.

This command can be used to steer one or more atoms to a new location in the simulation.

18.34.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The `fix_modify respa` option is supported by this fix. This allows to set at which level of the `r-RESPA` integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global 3-vector of forces, which can be accessed by various `output commands`. This is the total force on the group of atoms by the drag force. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

- flag1 flag2 ... flagN = Drude flag for each atom type (1 to N) in the system

18.35.2 Examples

```
fix 1 all drude 1 1 0 1 0 2 2 2
fix 1 all drude C C N C N D D D
```

18.35.3 Description

Assign each atom type in the system to be one of 3 kinds of atoms within the Drude polarization model. This fix is designed to be used with the thermalized Drude oscillator model. Polarizable models in LAMMPS are described on the Howto polarizable doc page.

The three possible types can be designated with an integer (0,1,2) or capital letter (N,C,D):

- 0 or N = non-polarizable atom (not part of Drude model)
- 1 or C = Drude core
- 2 or D = Drude electron

18.35.4 Restrictions

This fix should be invoked before any other commands that implement the Drude oscillator model, such as fix langevin/drude, fix drude/transform, compute temp/drude, pair_style thole.
18.35.5 Related commands

fix langevin/drude, fix drude/transform, compute temp/drude, pair_style thole

18.35.6 Default

18.36 fix drude/transform/direct command

18.37 fix drude/transform/inverse command

18.37.1 Syntax

fix ID group-ID style keyword value ...

- ID, group-ID are documented in fix command
- style = drude/transform/direct or drude/transform/inverse

18.37.2 Examples

```
fix 3 all drude/transform/direct
fix 1 all drude/transform/inverse
```

18.37.3 Description

Transform the coordinates of Drude oscillators from real to reduced and back for thermalizing the Drude oscillators as described in (Lamoureux) using a Nose-Hoover thermostat. This fix is designed to be used with the thermalized Drude oscillator model. Polarizable models in LAMMPS are described on the Howto polarizable doc page.

Drude oscillators are a pair of atoms representing a single polarizable atom. Ideally, the mass of Drude particles would vanish and their positions would be determined self-consistently by iterative minimization of the energy, the cores’ positions being fixed. It is however more efficient and it yields comparable results, if the Drude oscillators (the motion of the Drude particle relative to the core) are thermalized at a low temperature. In that case, the Drude particles need a small mass.

The thermostats act on the reduced degrees of freedom, which are defined by the following equations. Note that in these equations upper case denotes atomic or center of mass values and lower case denotes Drude particle or dipole values. Primes denote the transformed (reduced) values, while bare letters denote the original values.

Masses:

\[ M' = M + m \]
\[ m' = \frac{M m}{M'} \]

Positions:

\[ X' = \frac{M X + m x}{M'} \]
\[ x' = x - X \]

Velocities:
\[ V' = \frac{MV + mv}{M'} \]
\[ v' = v - V \]

Forces:
\[ F' = F + f \]
\[ f' = \frac{Mf - mF}{M'} \]

This transform conserves the total kinetic energy
\[ \frac{1}{2} (M V^2 + m v^2) = \frac{1}{2} (M' V'^2 + m' v'^2) \]

and the virial defined with absolute positions
\[ X F + x f = X' F' + x' f' \]

This fix requires each atom know whether it is a Drude particle or not. You must therefore use the fix drude command to specify the Drude status of each atom type.

**Note:** only the Drude core atoms need to be in the group specified for this fix. A Drude electron will be transformed together with its core even if it is not itself in the group. It is safe to include Drude electrons or non-polarizable atoms in the group. The non-polarizable atoms will simply not be transformed.

This fix does NOT perform time integration. It only transform masses, coordinates, velocities and forces. Thus you must use separate time integration fixes, like fix nve or fix npt to actually update the velocities and positions of atoms. In order to thermalize the reduced degrees of freedom at different temperatures, two Nose-Hoover thermostats must be defined, acting on two distinct groups.

**Note:** The fix drude/transform/direct command must appear before any Nose-Hoover thermostating fixes. The fix drude/transform/inverse command must appear after any Nose-Hoover thermostating fixes.

Example:
```
fix fDIRECT all drude/transform/direct
fix fNVT gCORES nvt temp 300.0 300.0 100
fix fNVT gDRUDES nvt temp 1.0 1.0 100
fix fINVERSE all drude/transform/inverse
compute TDRUDE all temp/drude
```
In this example, \texttt{gCORES} is the group of the atom cores and \texttt{gDRUDES} is the group of the Drude particles (electrons). The centers of mass of the Drude oscillators will be thermostatted at 300.0 and the internal degrees of freedom will be thermostatted at 1.0. The temperatures of cores and Drude particles, in center-of-mass and relative coordinates, are calculated using \texttt{compute temp/drude}.

In addition, if you want to use a barostat to simulate a system at constant pressure, only one of the Nose-Hoover fixes must be \texttt{npt}, the other one should be \texttt{nvt}. You must add a \texttt{compute temp/com} and a \texttt{fix modify} command so that the temperature of the \texttt{npt} fix be just that of its group (the Drude cores) but the pressure be the overall pressure \texttt{thermo_press}.

Example:

```plaintext
compute cTEMP_CORE gCORES temp/com
fix fDIRECT all drude/transform/direct
fix fnPT gCORES npt temp 298.0 298.0 100 iso 1.0 1.0 500
fix modify fnPT temp cTEMP_CORE press thermo_press
fix fnVT gDRUDES nvt temp 5.0 5.0 100
fix fINVERSE all drude/transform/inverse
```

In this example, \texttt{gCORES} is the group of the atom cores and \texttt{gDRUDES} is the group of the Drude particles. The centers of mass of the Drude oscillators will be thermostatted at 298.0 and the internal degrees of freedom will be thermostatted at 5.0. The whole system will be barostatted at 1.0.

In order to avoid the flying ice cube problem (irreversible transfer of linear momentum to the center of mass of the system), you may need to add a \texttt{fix momentum} command:

```plaintext
fix fMOMENTUM all momentum 100 linear 1 1 1
```

### 18.37.4 Restart, fix modify, output, run start/stop, minimize info

18.38 fix dt/reset command

18.38.1 Syntax

```plaintext
fix ID group-ID dt/reset N Tmin Tmax Xmax keyword values ...
```

- ID, group-ID are documented in `fix` command
- `dt/reset` = style name of this fix command
- `N` = re-compute `dt` every `N` timesteps
- `Tmin` = minimum `dt` allowed which can be NULL (time units)
- `Tmax` = maximum `dt` allowed which can be NULL (time units)
- `Xmax` = maximum distance for an atom to move in one timestep (distance units)
- zero or more keyword/value pairs may be appended
  - keyword = emax or units

```plaintext
emax value = Emax
Emax = maximum kinetic energy change for an atom in one timestep (energy units)
```

```plaintext
units value = lattice or box
lattice = Xmax is defined in lattice units
box = Xmax is defined in simulation box units
```

18.38.2 Examples

```plaintext
fix 5 all dt/reset 10 1.0e-5 0.01 0.1
fix 5 all dt/reset 10 0.01 2.0 0.2 units box
fix 5 all dt/reset 5 NULL 0.001 0.5 emax 30 units box
```

18.38.3 Description

Reset the timestep size every `N` steps during a run, so that no atom moves further than the specified `Xmax` distance, based on current atom velocities and forces. Optionally an additional criterion is imposed by the `emax` keyword, so that no atom’s kinetic energy changes by more than the specified `Emax`.

This can be useful when starting from a configuration with overlapping atoms, where forces will be large. Or it can be useful when running an impact simulation where one or more high-energy atoms collide with a solid, causing a damage cascade.

This fix overrides the timestep size setting made by the `timestep` command. The new timestep size `dt` is computed in the following manner.

For each atom, the timestep is computed that would cause it to displace `Xmax` on the next integration step, as a function of its current velocity and force. Since performing this calculation exactly would require the solution to a quartic equation, a cheaper estimate is generated. The estimate is conservative in that the atom’s displacement is guaranteed not to exceed `Xmax`, though it may be smaller.

In addition if the `emax` keyword is used, the specified `Emax` value is enforced as a limit on how much an atom’s kinetic energy can change. If the timestep required is even smaller than for the `Xmax` displacement, then the smaller timestep is used.
Given this putative timestep for each atom, the minimum timestep value across all atoms is computed. Then the \( T_{\text{min}} \) and \( T_{\text{max}} \) bounds are applied, if specified. If one (or both) is specified as NULL, it is not applied.

When the run style is respa, this fix resets the outer loop (largest) timestep, which is the same timestep that the timestep command sets.

Note that the cumulative simulation time (in time units), which accounts for changes in the timestep size as a simulation proceeds, can be accessed by the thermo_style time keyword.

### 18.38.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix computes a global scalar which can be accessed by various output commands. The scalar stores the last timestep on which the timestep was reset to a new value.

The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

### 18.38.5 Restrictions

none

### 18.38.6 Related commands

timestep

### 18.38.7 Default

The option defaults are units = lattice, and no emax kinetic energy limit.

### 18.39 fix efield command

#### 18.39.1 Syntax

| fix ID group-ID efield ex ey ez keyword value ... |

- ID, group-ID are documented in fix command
- efield = style name of this fix command
- \( ex,ey,ez \) = E-field component values (electric field units)
- any of \( ex,ey,ez \) can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
- keyword = region or energy

---

18.39. fix efield command
region value = region-ID
    region-ID = ID of region atoms must be in to have added force
energy value = v_name
    v_name = variable with name that calculates the potential energy of each atom in the added E-field

18.39.2 Examples

    fix kick external-field efield 1.0 0.0 0.0
    fix kick external-field efield 0.0 0.0 v_oscillate

18.39.3 Description

Add a force \( F = qE \) to each charged atom in the group due to an external electric field being applied to the system. If the system contains point-dipoles, also add a torque on the dipoles due to the external electric field.

For any of the 3 quantities defining the E-field components can be specified as an equal-style or atom-style variable, namely \( ex, ey, ez \). If the value is a variable, it should be specified as \( v\_name \), where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the E-field component.

For point-dipoles, equal-style variables can be used, but atom-style variables are not currently supported, since they imply a spatial gradient in the electric field which means additional terms with gradients of the field are required for the force and torque on dipoles.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent E-field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent E-field with optional time-dependence as well.

If the region keyword is used, the atom must also be in the specified geometric region in order to have force added to it.

Adding a force or torque to atoms implies a change in their potential energy as they move or rotate due to the applied E-field.

For dynamics via the “run” command, this energy can be optionally added to the system’s potential energy for thermodynamic output (see below). For energy minimization via the “minimize” command, this energy must be added to the system’s potential energy to formulate a self-consistent minimization problem (see below).

The energy keyword is not allowed if the added field is a constant vector \( (ex, ey, ez) \), with all components defined as numeric constants and not as variables. This is because LAMMPS can compute the energy for each charged particle directly as \( E = -x \cdot qE = -q (x*ex + y*ey + z*ez) \), so that -Grad(E) = F. Similarly for point-dipole particles the energy can be computed as \( E = -\mu \cdot E = -(mux*ex + muy*ey + muz*ez) \).

The energy keyword is optional if the added force is defined with one or more variables, and if you are performing dynamics via the run command. If the keyword is not used, LAMMPS will set the energy to 0.0, which is typically fine for dynamics.

The energy keyword is required if the added force is defined with one or more variables, and you are performing energy minimization via the “minimize” command for charged particles. It is not required for point-dipoles, but a warning is issued since the minimizer in LAMMPS does not rotate dipoles, so you should not expect to be able to minimize the orientation of dipoles in an applied electric field.
The `energy` keyword specifies the name of an atom-style variable which is used to compute the energy of each atom as function of its position. Like variables used for `ex`, `ey`, `ez`, the energy variable is specified as `v_name`, where name is the variable name.

Note that when the `energy` keyword is used during an energy minimization, you must insure that the formula defined for the atom-style variable is consistent with the force variable formulas, i.e. that \(-\text{Grad}(E) = F\). For example, if the force due to the electric field were a spring-like \(F = kx\), then the energy formula should be \(E = -0.5kx^2\). If you don’t do this correctly, the minimization will not converge properly.

### 18.39.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The `fix_modify energy` option is supported by this fix to add the potential “energy” inferred by the added force due to the electric field to the system’s potential energy as part of thermodynamic output. This is a fictitious quantity but is needed so that the `minimize` command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added force due to the electric field.

The `fix_modify virial` option is supported by this fix to add the contribution due to the added forces on atoms to the system’s virial as part of thermodynamic output. The default is `virial no`.

The `fix_modify respa` option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix adding its forces. Default is the outermost level.

This fix computes a global scalar and a global 3-vector of forces, which can be accessed by various output commands. The scalar is the potential energy discussed above. The vector is the total force added to the group of atoms. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command.

The forces due to this fix are imposed during an energy minimization, invoked by the `minimize` command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the `fix_modify energy` option for this fix.

### 18.39.5 Restrictions

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

fix fcold all ehex 1 -0.075 region rcold constrain com
fix frattle all rattle 1e-10 400 0 b 1 a 1
```
18.40.3 Description

This fix implements the asymmetric version of the enhanced heat exchange algorithm (Wirnsberger). The eHEX algorithm is an extension of the heat exchange algorithm (Ikeshoji) and adds an additional coordinate integration to account for higher-order truncation terms in the operator splitting. The original HEX algorithm (implemented as fix heat) is known to exhibit a slight energy drift limiting the accessible simulation times to a few nanoseconds. This issue is greatly improved by the new algorithm decreasing the energy drift by at least a factor of a hundred (LJ and SPC/E water) with little computational overhead.

In both algorithms (non-translational) kinetic energy is constantly swapped between regions (reservoirs) to impose a heat flux onto the system. The equations of motion are therefore modified if a particle $i$ is located inside a reservoir $\Gamma_k$ where $k > 0$. We use $\Gamma_0$ to label those parts of the simulation box which are not thermostatted.) The input parameter region-ID of this fix corresponds to $k$. The energy swap is modelled by introducing an additional thermostatting force to the equations of motion, such that the time evolution of coordinates and momenta of particle $i$ becomes (Wirnsberger)

\[
\dot{r}_i = v_i,
\]
\[
\dot{v}_i = \frac{f_i}{m_i} + \frac{g_i}{m_i}.
\]

The thermostatting force is given by

\[
g_i = \begin{cases} 
\frac{m_i}{2} \frac{F_{\Gamma_k(r_i)}}{K_{\Gamma_k(r_i)}} \left( v_i - v_{\Gamma_k(r_i)} \right) & k(r_i) > 0 \text{ (inside a reservoir)}, \\
0 & \text{otherwise}, 
\end{cases}
\]

where $m_i$ is the mass and $k(r_i)$ maps the particle position to the respective reservoir. The quantity $F_{\Gamma_k(r_i)}$ corresponds to the input parameter $F$, which is the energy flux into the reservoir. Furthermore, $K_{\Gamma_k(r_i)}$ and $v_{\Gamma_k(r_i)}$ denote the non-translational kinetic energy and the center of mass velocity of that reservoir. The thermostatting force does not affect the center of mass velocities of the individual reservoirs and the entire simulation box. A derivation of the equations and details on the numerical implementation with velocity Verlet in LAMMPS can be found in reference “(Wirnsberger)”

**Note:** This fix only integrates the thermostatting force and must be combined with another integrator, such as fix nve, to solve the full equations of motion.

This fix is different from a thermostat such as fix nvt or fix temp/rescale in that energy is added/subtracted continually. Thus if there is not another mechanism in place to counterbalance this effect, the entire system will heat or cool continuously.

**Note:** If heat is subtracted from the system too aggressively so that the group’s kinetic energy would go to zero, then LAMMPS will halt with an error message. Increasing the value of nevery means that heat is added/subtracted less frequently but in larger portions. The resulting temperature profile will therefore be the same.

This fix will default to fix heat (HEX algorithm) if the keyword hex is specified.

**Compatibility with SHAKE and RATTLE (rigid molecules):**

This fix is compatible with fix shake and fix rattle. If either of these constraining algorithms is specified in the input script and the keyword constrain is set, the bond distances will be corrected a second time at the end of the integration step. It is recommended to specify the keyword com in addition to the keyword constrain. With this option all sites of a constrained cluster are rescaled, if its center of mass is located inside the region. Rescaling all sites of a cluster by...
the same factor does not introduce any velocity components along fixed bonds. No rescaling takes place if the center of mass lies outside the region.

**Note:** You can only use the keyword *com* along with *constrain*.

To achieve the highest accuracy it is recommended to use *fix rattle* with the keywords *constrain* and *com* as shown in the second example. Only if RATTLE is employed, the velocity constraints will be satisfied.

**Note:** Even if RATTLE is used and the keywords *com* and *constrain* are both set, the coordinate constraints will not necessarily be satisfied up to the target precision. The velocity constraints are satisfied as long as all sites of a cluster are rescaled (keyword *com*) and the cluster does not span adjacent reservoirs. The current implementation of the eHEX algorithm introduces a small error in the bond distances, which goes to zero with order three in the timestep. For example, in a simulation of SPC/E water with a timestep of 2 fs the maximum relative error in the bond distances was found to be on the order of $10^{-7}$ for relatively large temperature gradients. A higher precision can be achieved by decreasing the timestep.

### 18.40.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 18.40.5 Restrictions

This fix is part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

18.41 fix electron/stopping command

18.41.1 Syntax

```plaintext
class ID group-ID electron/stopping Ecut file keyword value ...
```

- ID, group-ID are documented in `fix` command
- electron/stopping = style name of this fix command
- Ecut = minimum kinetic energy for electronic stopping (energy units)
- file = name of the file containing the electronic stopping power table
- zero or more keyword/value pairs may be appended to args
- keyword = `region` or `minneigh`
  - region value = region-ID
    - region-ID = region, whose atoms will be affected by this fix
  - minneigh value = minneigh
    - minneigh = minimum number of neighbors an atom to have stopping applied

18.41.2 Examples

```plaintext
fix el all electron/stopping 10.0 elstop-table.txt
fix el all electron/stopping 10.0 elstop-table.txt minneigh 3
fix el mygroup electron/stopping 1.0 elstop-table.txt region bulk
```

18.41.3 Description

This fix implements inelastic energy loss for fast projectiles in solids. It applies a friction force to fast moving atoms to slow them down due to electronic stopping (energy lost via electronic collisions per unit of distance). This fix should be used for simulation of irradiation damage or ion implantation, where the ions can lose noticeable amounts of energy from electron excitations. If the electronic stopping power is not considered, the simulated range of the ions can be severely overestimated (Nordlund98, Nordlund95).

The electronic stopping is implemented by applying a friction force to each atom as:

\[ \vec{F}_i = \vec{F}_i^0 - \frac{\vec{v}_i}{\|\vec{v}_i\|} \cdot S_e \]

where \( \vec{F}_i \) is the resulting total force on the atom, \( \vec{F}_i^0 \) is the original force applied to the atom, \( \vec{v}_i \) is its velocity and \( S_e \) is the stopping power of the ion.

**Note:** In addition to electronic stopping, atomic cascades and irradiation simulations require the use of an adaptive timestep (see `fix dt/reset`) and the repulsive ZBL potential (see ZBL potential) or similar. Without these settings the interaction between the ion and the target atoms will be faulty. It is also common to use in such simulations a thermostat (`fix nvt`) in the borders of the simulation cell.

**Note:** This fix removes energy from fast projectiles without depositing it as a heat to the simulation cell. Such implementation might lead to the unphysical results when the amount of energy deposited to the electronic system is
large, e.g. simulations of Swift Heavy Ions (energy per nucleon of 100 keV/amu or higher) or multiple projectiles. You could compensate energy loss by coupling bulk atoms with some thermostat or control heat transfer between electronic and atomic subsystems with the two-temperature model \((\text{fix}_\text{ttm})\).

At low velocities the electronic stopping is negligible. The electronic friction is not applied to atoms whose kinetic energy is smaller than \(E_{\text{cut}}\), or smaller than the lowest energy value given in the table in \textit{file}. Electronic stopping should be applied only when a projectile reaches bulk material. This fix scans neighbor list and excludes atoms with fewer than \(\text{minneigh}\) neighbors (by default one). If the pair potential cutoff is large, \(\text{minneigh}\) should be increased, though not above the number of nearest neighbors in bulk material. An alternative is to disable the check for neighbors by setting \(\text{minneigh}\) to zero and using the \textit{region} keyword. This is necessary when running simulations of cluster bombardment.

If the \textit{region} keyword is used, the atom must also be in the specified geometric \textit{region} in order to have electronic stopping applied to it. This is useful if the position of the bulk material is fixed. By default the electronic stopping is applied everywhere in the simulation cell.

The energy ranges and stopping powers are read from the file \textit{file}. Lines starting with \# and empty lines are ignored. Otherwise each line must contain exactly \(N+1\) numbers, where \(N\) is the number of atom types in the simulation.

The first column is the energy for which the stopping powers on that line apply. The energies must be sorted from the smallest to the largest. The other columns are the stopping powers \(S_e\) for each atom type, in ascending order, in force units. The stopping powers for intermediate energy values are calculated with linear interpolation between 2 nearest points.

For example:

```
# This is a comment
# atom-1 atom-2
# eV eV/Ang eV/Ang # units metal
10 0 0
250 60 80
750 100 150
```

If an atom which would have electronic stopping applied to it has a kinetic energy higher than the largest energy given in \textit{file}, LAMMPS will exit with an error message.

The stopping power depends on the energy of the ion and the target material. The electronic stopping table can be obtained from scientific publications, experimental databases or by using \textit{SRIM} software. Other programs such as \textit{CasP} or \textit{PASS} can calculate the energy deposited as a function of the impact parameter of the ion; these results can be used to derive the stopping power.

### 18.41.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to \textit{binary restart files}.

The \textit{fix\_modify} options are not supported.

This fix computes a global scalar, which can be accessed by various \textit{output commands}. The scalar is the total energy loss from electronic stopping applied by this fix since the start of the latest run. It is considered “intensive”.

The \textit{start/stop} keywords of the \textit{run} command have no effect on this fix.
18.41.5 Restrictions

This pair style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.41.6 Default

The default is no limitation by region, and minneigh = 1.

18.42 fix enforce2d command

Accelerator Variants: enforce2d/kk

18.42.1 Syntax

```plaintext
fix ID group-ID enforce2d
```

- ID, group-ID are documented in fix command
- enforce2d = style name of this fix command

18.42.2 Examples

```plaintext
fix 5 all enforce2d
```

18.42.3 Description

Zero out the z-dimension velocity and force on each atom in the group. This is useful when running a 2d simulation to insure that atoms do not move from their initial z coordinate.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

18.42.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

18.43 fix eos/cv command

18.43.1 Syntax

fix ID group-ID eos/cv cv

- ID, group-ID are documented in fix command
- eos/cv = style name of this fix command
- cv = constant-volume heat capacity (energy/temperature units)
18.43.2 Examples

fix 1 all eos/cv 0.01

18.43.3 Description

Fix *eos/cv* applies a mesoparticle equation of state to relate the particle internal energy \( u_i \) to the particle internal temperature \( \theta_i \). The *eos/cv* mesoparticle equation of state requires the constant-volume heat capacity, and is defined as follows:

\[
  u_i = u_i^{\text{mech}} + u_i^{\text{cond}} = C_V \theta_i
\]

where \( C_V \) is the constant-volume heat capacity, \( u_i^{\text{cond}} \) is the internal conductive energy, and \( u_i^{\text{mech}} \) is the internal mechanical energy. Note that alternative definitions of the mesoparticle equation of state are possible.

18.43.4 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This command also requires use of the *atom_style dpd* command.

18.43.5 Related commands

18.44 fix eos/table command

18.44.1 Syntax

```
fix ID group-ID eos/table style file N keyword
```

- ID, group-ID are documented in *fix* command
- eos/table = style name of this fix command
- style = *linear* = method of interpolation
- file = filename containing the tabulated equation of state
18.44.2 Examples

```plaintext
fix 1 all eos/table linear eos.table 100000 KEYWORD
```

18.44.3 Description

Fix `eos/table` applies a tabulated mesoparticle equation of state to relate the particle internal energy \( u_i \) to the particle internal temperature \( \text{dpdTheta}_i \).

Fix `eos/table` creates interpolation tables of length \( N \) from internal energy values listed in a file as a function of internal temperature.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy values at each of \( N \) internal temperatures, and vice versa. During a simulation, these tables are used to interpolate internal energy or temperature values as needed. The interpolation is done with the `linear` style.

For the `linear` style, the internal temperature is used to find 2 surrounding table values from which an internal energy is computed by linear interpolation, and vice versa.

The filename specifies a file containing tabulated internal temperature and internal energy values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# EOS TABLE (one or more comment or blank lines)
KEYWORD (keyword is first text on line)
N 500 (N parameter)
   (blank)
1 1.00 0.000 (index, internal temperature, internal energy)
2 1.02 0.001
...
500 10.0 0.500
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the fix command.

The next line lists the number of table entries. The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the \( N \) specified in the `fix eos/table` command. Let \( N_{\text{table}} = N \) in the fix command, and \( N_{\text{file}} = “N” \) in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the \( N_{\text{file}} \) tabulated values as nodal points. It uses these to interpolate as needed to generate energy and temperature values at \( N_{\text{table}} \) different points. The resulting tables of length \( N_{\text{table}} \) are then used as described above, when computing energy and temperature relationships. This means that if you want the interpolation tables of length \( N_{\text{table}} \) to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set \( N_{\text{table}} = N_{\text{file}} \).

Following a blank line, the next \( N \) lines list the tabulated values. On each line, the first value is the index from 1 to \( N \), the second value is the internal temperature (in temperature units), the third value is the internal energy (in energy units).

Note that the internal temperature and internal energy values must increase from one line to the next.
Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

18.44.4 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This command also requires use of the atom_style dpd command.

The equation of state must be a monotonically increasing function.

An error will occur if the internal temperature or internal energies are not within the table cutoffs.

18.44.5 Related commands

fix shardlow, pair dpd/fdt

18.45 fix eos/table/rx command

Accelerator Variants: eos/table/rx/kk

18.45.1 Syntax

fix ID group-ID eos/table/rx style file1 N keyword ...

- ID, group-ID are documented in fix command
- eos/table/rx = style name of this fix command
- style = linear = method of interpolation
- file1 = filename containing the tabulated equation of state
- N = use N values in linear tables
- keyword = name of table keyword corresponding to table file
- file2 = filename containing the heats of formation of each species (optional)
- deltaHf = heat of formation for a single species in energy units (optional)
- energyCorr = energy correction in energy units (optional)
- tempCorrCoeff = temperature correction coefficient (optional)
### 18.45.2 Examples

```plaintext
fix 1 all eos/table/rx linear eos.table 10000 KEYWORD thermo.table
fix 1 all eos/table/rx linear eos.table 10000 KEYWORD 1.5
fix 1 all eos/table/rx linear eos.table 10000 KEYWORD 1.5 0.025 0.0
```

### 18.45.3 Description

Fix `eos/table/rx` applies a tabulated mesoparticle equation of state to relate the concentration-dependent particle internal energy \( (u_i) \) to the particle internal temperature \( (\theta_i) \).

The concentration-dependent particle internal energy \( (u_i) \) is computed according to the following relation:

\[
U_i = \sum_{j=1}^{m} c_{i,j} (u_j + \Delta H_{f,j}) + \frac{3k_b T}{2} + Nk_b T
\]

where \( m \) is the number of species, \( c_{i,j} \) is the concentration of species \( j \) in particle \( i \), \( u_j \) is the internal energy of species \( j \), \( \Delta H_{f,j} \) is the heat of formation of species \( j \), \( N \) is the number of molecules represented by the coarse-grained particle, \( k_b \) is the Boltzmann constant, and \( T \) is the temperature of the system. Additionally, it is possible to modify the concentration-dependent particle internal energy relation by adding an energy correction, temperature-dependent correction, and/or a molecule-dependent correction. An energy correction can be specified as a constant (in energy units). A temperature correction can be specified by multiplying a temperature correction coefficient by the internal temperature. A molecular correction can be specified by multiplying a molecule correction coefficient by the average number of product gas particles in the coarse-grain particle.

Fix `eos/table/rx` creates interpolation tables of length \( N \) from \( m \) internal energy values of each species \( u_j \) listed in a file as a function of internal temperature. During a simulation, these tables are used to interpolate internal energy or temperature values as needed. The interpolation is done with the `linear` style. For the `linear` style, the internal temperature is used to find 2 surrounding table values from which an internal energy is computed by linear interpolation. A secant solver is used to determine the internal temperature from the internal energy.

The first filename specifies a file containing tabulated internal temperature and \( m \) internal energy values for each species \( u_j \). The keyword specifies a section of the file. The format of this file is described below.

The second filename specifies a file containing heat of formation \( \Delta H_{f,j} \) for each species.

In cases where the coarse-grain particle represents a single molecular species (i.e., no reactions occur and fix `rx` is not present in the input file), fix `eos/table/rx` can be applied in a similar manner to fix `eos/table` within a non-reactive DPD simulation. In this case, the heat of formation filename is replaced with the heat of formation value for the single species. Additionally, the energy correction and temperature correction coefficients may also be specified as fix arguments.

The format of a tabulated file is as follows (without the parenthesized comments):

```plaintext
# EOS TABLE (one or more comment or blank lines)

KEYWORD (keyword is first text on line)
N 500 h2 no2 n2 ... no (N parameter species1 species2 ... speciesN)
(blank)
1   1.00 0.000 ... 0.0000 (index, internal temperature, internal energy of species 1, ...
2   1.02 0.001 ... 0.0002, internal energy of species m)
...
500  10.0 0.500 ... 1.0000
```
A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the fix command.

The next line lists the number of table entries and the species names that correspond with all the species listed in the reaction equations through the *fix rx* command. The parameter “N” is required and its value is the number of table entries that follow. Let Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the internal temperature (in temperature units), the third value until the \( m+3 \) value are the internal energies of the \( m \) species (in energy units).

Note that all internal temperature and internal energy values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

The format of a heat of formation file is as follows (without the parenthesized comments):

```
# HEAT OF FORMATION TABLE (one or more comment or blank lines)

    (blank)

(h2  0.00)  (species name, heat of formation)
(no2 0.34)
(n2  0.00)
(...
(no  0.93)
```

Note that the species can be listed in any order. The tag that is used as the species name must correspond with the tags used to define the reactions with the *fix rx* command.

Alternatively, corrections to the EOS can be included by specifying three additional columns that correspond to the energy correction, the temperature correction coefficient and molecule correction coefficient. In this case, the format of the file is as follows:

```
# HEAT OF FORMATION TABLE (one or more comment or blank lines)

    (blank)

(h2  0.00 1.23 0.025 0.0  (species name, heat of formation, energy correction,
  temperature correction coefficient, molecule correction coefficient)
(no2 0.34 0.00 0.000 -1.76
(n2  0.00 0.00 0.000 -1.76
(...
(no  0.93 0.00 0.000 -1.76
```

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.
See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

18.45.4 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This command also requires use of the atom_style dpd command.

The equation of state must be a monotonically increasing function.

An error will occur if the internal temperature or internal energies are not within the table cutoffs.

18.45.5 Related commands

18.46 fix evaporate command

18.46.1 Syntax

```
fix ID group-ID evaporate N M region-ID seed
```

- ID, group-ID are documented in fix command
- evaporate = style name of this fix command
- N = delete atoms every this many timesteps
- M = number of atoms to delete each time
- region-ID = ID of region within which to perform deletions
- seed = random number seed to use for choosing atoms to delete
- zero or more keyword/value pairs may be appended

```
keyword = molecule
    molecule value = no or yes
```
18.46.2 Examples

```
fix 1 solvent evaporate 1000 10 surface 49892
fix 1 solvent evaporate 1000 10 surface 38277 molecule yes
```

18.46.3 Description

Remove M atoms from the simulation every N steps. This can be used, for example, to model evaporation of solvent particles or molecules (i.e. drying) of a system. Every N steps, the number of atoms in the fix group and within the specified region are counted. M of these are chosen at random and deleted. If there are less than M eligible particles, then all of them are deleted.

If the setting for the `molecule` keyword is `no`, then only single atoms are deleted. In this case, you should insure you do not delete only a portion of a molecule (only some of its atoms), or LAMMPS will soon generate an error when it tries to find those atoms. LAMMPS will warn you if any of the atoms eligible for deletion have a non-zero molecule ID, but does not check for this at the time of deletion.

If the setting for the `molecule` keyword is `yes`, then when an atom is chosen for deletion, the entire molecule it is part of is deleted. The count of deleted atoms is incremented by the number of atoms in the molecule, which may make it exceed \( M \). If the molecule ID of the chosen atom is 0, then it is assumed to not be part of a molecule, and just the single atom is deleted.

As an example, if you wish to delete 10 water molecules every \( N \) steps, you should set \( M \) to 30. If only the water’s oxygen atoms were in the fix group, then two hydrogen atoms would be deleted when an oxygen atom is selected for deletion, whether the hydrogen atoms are inside the evaporation region or not.

Note that neighbor lists are re-built on timesteps that atoms are removed. Thus you should not remove atoms too frequently or you will incur overhead due to the cost of building neighbor lists.

Note: If you are monitoring the temperature of a system where the atom count is changing due to evaporation, you typically should use the `compute_modify dynamic yes` command for the temperature compute you are using.

18.46.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to `binary restart files`. None of the `fix_modify` options are relevant to this fix. This fix computes a global scalar, which can be accessed by various `output commands`. The scalar is the cumulative number of deleted atoms. The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during `energy minimization`.

18.46.5 Restrictions

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

\text{fix} & \ 1 \ \text{all} \ \text{external} \ \text{pf/array} \ \text{10}
\end{align*}
\]

18.47.3 Description

This fix allows external programs that are running LAMMPS through its library interface to modify certain LAMMPS properties on specific timesteps, similar to the way other fixes do. The external driver can be a C/C++ or Fortran program or a Python script.

If mode is pf/callback then the fix will make a callback every Ncall timesteps or minimization iterations to the external program. The external program computes forces on atoms by setting values in an array owned by the fix. The fix then adds these forces to each atom in the group, once every Napply steps, similar to the way the fix addforce command works. Note that if Ncall > Napply, the force values produced by one callback will persist, and be used multiple times to update atom forces.

The callback function “foo” is invoked by the fix as:

\[
\text{foo(}\ void \ *\text{ptr, bigint timestep, int nlocal, tagint *ids, double **x, double* fexternal)}\]

The arguments are as follows:
• \textit{ptr} = pointer provided by and simply passed back to external driver
• \textit{timestep} = current LAMMPS timestep
• \textit{nlocal} = \# of atoms on this processor
• \textit{ids} = list of atom IDs on this processor
• \textit{x} = coordinates of atoms on this processor
• \textit{fexternal} = forces to add to atoms on this processor

Note that \textit{timestep} is a “bigint” which is defined in src/lmptype.h, typically as a 64-bit integer. And \textit{ids} is a pointer to type “tagint” which is typically a 32-bit integer unless LAMMPS is compiled with -DLAMMPS_BIGBIGN. For more info please see the build settings section of the manual. Finally, \textit{fexternal} are the forces returned by the driver program.

The fix has a set\_callback() method which the external driver can call to pass a pointer to its \textit{foo}() function. See the couple/lammps\_quest/Lmpqst.cpp file in the LAMMPS distribution for an example of how this is done. This sample application performs classical MD using quantum forces computed by a density functional code Quest.

If mode is \texttt{pf/array} then the fix simply stores force values in an array. The fix adds these forces to each atom in the group, once every \textit{Napply} steps, similar to the way the \textit{fix addforce} command works.

The name of the public force array provided by the FixExternal class is

\begin{verbatim}
double **fexternal;
\end{verbatim}

It is allocated by the FixExternal class as an (N,3) array where N is the number of atoms owned by a processor. The 3 corresonds to the \textit{fx}, \textit{fy}, \textit{fz} components of force.

It is up to the external program to set the values in this array to the desired quantities, as often as desired. For example, the driver program might perform an MD run in stages of 1000 timesteps each. In between calls to the LAMMPS \textit{run} command, it could retrieve atom coordinates from LAMMPS, compute forces, set values in \textit{fexternal}, etc.

To use this fix during energy minimization, the energy corresponding to the added forces must also be set so as to be consistent with the added forces. Otherwise the minimization will not converge correctly. Correspondingly, the global virial needs to be updated to be use this fix with variable cell calculations (e.g. \textit{fix box/relax} or \textit{fix npt}).

This can be done from the external driver by calling these public methods of the FixExternal class:

\begin{verbatim}
void set_energy_global(double eng);
void set_virial_global(double *virial);
\end{verbatim}

where \textit{eng} is the potential energy, and \textit{virial} an array of the 6 stress tensor components. Eng is an extensive quantity, meaning it should be the sum over per-atom energies of all affected atoms. It should also be provided in energy units consistent with the simulation. See the details below for how to insure this energy setting is used appropriately in a minimization.

Additional public methods that the caller can use to update system properties are:

\begin{verbatim}
void set_energy_peratom(double *eng);
void set_virial_peratom(double **virial);
void set_vector_length(int n);
void set_vector(int idx, double val);
\end{verbatim}

These allow to set per-atom energy contributions, per-atom stress contributions, the length and individual values of a global vector of properties that the caller code may want to communicate to LAMMPS (e.g. for use in \textit{fix ave/time} or in \textit{equal-style variables} or for \textit{custom thermo output}. 

\section{18.47. \texttt{fix external} command}
18.47.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the potential “energy” set by the external driver to the system’s potential energy as part of thermodynamic output. This is a fictitious quantity but is needed so that the minimize command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added force.

The fix_modify virial option is supported by this fix to add the contribution due to the interactions computed by the external program to the system’s virial as part of thermodynamic output. The default is virial yes.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the potential energy discussed above. The scalar stored by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

---

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

18.47.5 Restrictions

none

18.47.6 Related commands

18.47.7 Default

none

18.48 fix ffl command

18.48.1 Syntax

fix ID id-group ffl tau Tstart Tstop seed [flip-type]

- ID, group-ID are documented in fix command
- ffl = style name of this fix command
- tau = thermostat parameter (positive real)
- Tstart, Tstop = temperature ramp during the run
- seed = random number seed to use for generating noise (positive integer)
- one more value may be appended
flip-type = determines the flipping type, can be chosen between rescale - no_flip - hard - soft, if no flip type is given, rescale will be chosen by default.

18.48.2 Examples

\begin{verbatim}
fix 3 boundary ffl 10 300 300 31415
fix 1 all ffl 100 500 500 9265 soft
\end{verbatim}

18.48.3 Description

Apply a Fast-Forward Langevin Equation (FFL) thermostat as described in (Hijazi). Contrary to \textit{fix langevin}, this fix performs both thermostatting and evolution of the Hamiltonian equations of motion, so it should not be used together with \textit{fix nve} – at least not on the same atom groups.

The time-evolution of a single particle undergoing Langevin dynamics is described by the equations

\[
\frac{dq}{dt} = \frac{p}{m},
\]

\[
\frac{dp}{dt} = -\gamma p + W + F,
\]

where \( F \) is the physical force, \( \gamma \) is the friction coefficient, and \( W \) is a Gaussian random force.

The friction coefficient is the inverse of the thermostat parameter: \( \gamma = 1/\tau \), with \( \tau \) the thermostat parameter \textit{tau}. The thermostat parameter is given in the time units, \( \gamma \) is in inverse time units.

Equilibrium sampling a temperature \( T \) is obtained by specifying the target value as the \textit{Tstart} and \textit{Tstop} arguments, so that the internal constants depending on the temperature are computed automatically.

The random number \textit{seed} must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The flipping type \textit{flip-type} can be chosen between 4 types described in (Hijazi). The flipping operation occurs during the thermostatting step and it flips the momenta of the atoms. If no_flip is chosen, no flip will be executed and the integration will be the same as a standard Langevin thermostat (Bussi). The other flipping types are: rescale - hard - soft.

18.48.4 Restart, fix_modify, output, run start/stop, minimize info

The instantaneous values of the extended variables are written to \textit{binary restart files}. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior. Note however that you should use a different seed each time you restart, otherwise the same sequence of random numbers will be used each time, which might lead to stochastic synchronization and subtle artifacts in the sampling.

This fix can ramp its target temperature over multiple runs, using the \textit{start} and \textit{stop} keywords of the \textit{run} command. See the \textit{run} command for details of how to do this.

The \textit{fix_modify energy} option is supported by this fix to add the energy change induced by Langevin thermostatting to the system’s potential energy as part of \textit{thermodynamic output}.

This fix computes a global scalar which can be accessed by various \textit{output commands}. The scalar is the cumulative energy change due to this fix. The scalar value calculated by this fix is “extensive”.

18.48. \textit{fix ffl} command
18.48.5 Restrictions

In order to perform constant-pressure simulations please use `fix press/berendsen`, rather than `fix npt`, to avoid duplicate integration of the equations of motion.

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

18.48.6 Related commands

`fix nvt, fix temp/rescale, fix viscous, fix nvt, pair_style dpd/tstat, fix gld, fix gle`

18.49 fix filter/corotate command

18.49.1 Syntax

```
fix ID group-ID filter/corotate keyword value ...
```

- ID, group-ID are documented in `fix` command
- one or more constraint/value pairs are appended
  - constraint = b or a or t or m
    - b values = one or more bond types
    - a values = one or more angle types
    - t values = one or more atom types
    - m value = one or more mass values

18.49.2 Examples

```
timestep 8
run_style respa 3 2 8 bond 1 pair 2 kspace 3
fix cor all filter/corotate m 1.0
fix cor all filter/corotate b 4 19 a 3 5 2
```

18.49.3 Description

This fix implements a corotational filter for a mollified impulse method. In biomolecular simulations, it allows the usage of larger timesteps for long-range electrostatic interactions. For details, see (Fath).

When using `run_style respa` for a biomolecular simulation with high-frequency covalent bonds, the outer time-step is restricted to below ~ 4fs due to resonance problems. This fix filters the outer stage of the respa and thus a larger (outer) time-step can be used. Since in large biomolecular simulations the computation of the long-range electrostatic contributions poses a major bottleneck, this can significantly accelerate the simulation.
The filter computes a cluster decomposition of the molecular structure following the criteria indicated by the options a, b, t and m. This process is similar to the approach in fix shake, however, the clusters are not kept constrained. Instead, the position is slightly modified only for the computation of long-range forces. A good cluster decomposition constitutes in building clusters which contain the fastest covalent bonds inside clusters.

If the clusters are chosen suitably, the run_style respa is stable for outer time-steps of at least 8fs.

---

### 18.49.4 Restart, fix_modify, output, run start/stop, minimize info

No information about these fixes is written to binary restart files. None of the fix_modify options are relevant to these fixes. No global or per-atom quantities are stored by these fixes for access by various output commands. No parameter of these fixes can be used with the start/stop keywords of the run command. These fixes are not invoked during energy minimization.

---

### 18.49.5 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info. Currently, it does not support molecule templates.

### 18.50 fix flow/gauss command

---

### 18.50.1 Syntax

```plaintext
fix ID group-ID flow/gauss xflag yflag zflag keyword
```

- ID, group-ID are documented in fix command
- flow/gauss = style name of this fix command
- xflag,yflag,zflag = 0 or 1
  - 0 = do not conserve current in this dimension
  - 1 = conserve current in this dimension
- zero or more keyword/value pairs may be appended
- keyword = energy
  - energy value = no or yes
    - no = do not compute work done by this fix
    - yes = compute work done by this fix
18.50.2 Examples

```plaintext
fix GD fluid flow/gauss 1 0 0
fix GD fluid flow/gauss 1 1 1 energy yes
```

18.50.3 Description

This fix implements the Gaussian dynamics (GD) method to simulate a system at constant mass flux (Strong). GD is a nonequilibrium molecular dynamics simulation method that can be used to study fluid flows through pores, pipes, and channels. In its original implementation GD was used to compute the pressure required to achieve a fixed mass flux through an opening. The flux can be conserved in any combination of the directions, x, y, or z, using xflag, yflag, zflag. This fix does not initialize a net flux through a system, it only conserves the center-of-mass momentum that is present when the fix is declared in the input script. Use the velocity command to generate an initial center-of-mass momentum.

GD applies an external fluctuating gravitational field that acts as a driving force to keep the system away from equilibrium. To maintain steady state, a profile-unbiased thermostat must be implemented to dissipate the heat that is added by the driving force. Compute temp/profile can be used to implement a profile-unbiased thermostat.

A common use of this fix is to compute a pressure drop across a pipe, pore, or membrane. The pressure profile can be computed in LAMMPS with compute stress/atom and fix ave/chunk, or with the hardy method in fix atc. Note that the simple compute stress/atom method is only accurate away from inhomogeneities in the fluid, such as fixed wall atoms. Further, the computed pressure profile must be corrected for the acceleration applied by GD before computing a pressure drop or comparing it to other methods, such as the pump method (Zhu). The pressure correction is discussed and described in (Strong).

For a complete example including the considerations discussed above, see the examples/USER/flow_gauss directory.

**Note:** Only the flux of the atoms in group-ID will be conserved. If the velocities of the group-ID atoms are coupled to the velocities of other atoms in the simulation, the flux will not be conserved. For example, in a simulation with fluid atoms and harmonically constrained wall atoms, if a single thermostat is applied to group all, the fluid atom velocities will be coupled to the wall atom velocities, and the flux will not be conserved. This issue can be avoided by thermostatting the fluid and wall groups separately.

Adding an acceleration to atoms does work on the system. This added energy can be optionally subtracted from the potential energy for the thermodynamic output (see below) to check that the timestep is small enough to conserve energy. Since the applied acceleration is fluctuating in time, the work cannot be computed from a potential. As a result, computing the work is slightly more computationally expensive than usual, so it is not performed by default. To invoke the work calculation, use the energy keyword. The fix_modify energy option also invokes the work calculation, and overrides an energy no setting here. If neither energy yes or fix_modify energy yes are set, the global scalar computed by the fix will return zero.

**Note:** In order to check energy conservation, any other fixes that do work on the system must have fix_modify energy yes set as well. This includes thermostat fixes and any constraints that hold the positions of wall atoms fixed, such as fix spring/self.

If this fix is used in a simulation with the rRESPA integrator, the applied acceleration must be computed and applied at the same rRESPA level as the interactions between the flowing fluid and the obstacle. The rRESPA level at which the acceleration is applied can be changed using the fix_modify respa option discussed below. If the flowing fluid and the obstacle interact through multiple interactions that are computed at different rRESPA levels, then there must be a separate flow/gauss fix for each level. For example, if the flowing fluid and obstacle interact through pairwise and long-range Coulomb interactions, which are computed at rRESPA levels 3 and 4, respectively, then there must be two separate flow/gauss fixes, one that specifies fix_modify respa 3 and one with fix_modify respa 4.
18.50.4 Restart, fix_modify, output, run start/stop, minimize info

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to subtract the work done from the system’s potential energy as part of thermodynamic output.

The fix_modify respa option is supported by this fix. This allows the user to set at which level of the rRESPA integrator the fix computes and adds the external acceleration. Default is the outermost level.

This fix computes a global scalar and a global 3-vector of forces, which can be accessed by various output commands. The scalar is the negative of the work done on the system, see above discussion. The vector is the total force that this fix applied to the group of atoms on the current timestep. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

18.50.5 Restrictions

none

18.50.6 Related commands

fix addforce, compute temp/profile, velocity

18.50.7 Default

The option default for the energy keyword is energy = no.

18.51 fix freeze command

Accelerator Variants: freeze/kk
18.51.1 Syntax

```
fix ID group-ID freeze
```

- ID, group-ID are documented in `fix` command
- freeze = style name of this fix command

18.51.2 Examples

```
fix 2 bottom freeze
```

18.51.3 Description

Zero out the force and torque on a granular particle. This is useful for preventing certain particles from moving in a simulation. The `granular pair styles` also detect if this fix has been defined and compute interactions between frozen and non-frozen particles appropriately, as if the frozen particle has infinite mass. A similar functionality for normal (point) particles can be obtained using `fix setforce`.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

18.51.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to `binary restart files`. None of the `fix_modify` options are relevant to this fix.

This fix computes a global 3-vector of forces, which can be accessed by various `output commands`. This is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during `energy minimization`.

---

LAMMPS Documentation
18.51.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

There can only be a single freeze fix defined. This is because other the granular pair styles treat frozen particles differently and need to be able to reference a single group to which this fix is applied.

\end{verbatim}

18.52.3 Description

This fix performs grand canonical Monte Carlo (GCMC) exchanges of atoms or molecules with an imaginary ideal gas reservoir at the specified T and chemical potential (\(\mu\)) as discussed in \cite{Frenkel}. It also attempts Monte Carlo (MC) moves (translations and molecule rotations) within the simulation cell or region. If used with the \texttt{fix nvt} command, simulations in the grand canonical ensemble (\(\muVT\), constant chemical potential, constant volume, and constant temperature) can be performed. Specific uses include computing isotherms in microporous materials, or computing vapor-liquid coexistence curves.

Every \(N\) timesteps the fix attempts both GCMC exchanges (insertions or deletions) and MC moves of gas atoms or molecules. On those timesteps, the average number of attempted GCMC exchanges is \(X\), while the average number of attempted MC moves is \(M\). For GCMC exchanges of either molecular or atomic gasses, these exchanges can be either deletions or insertions, with equal probability.

The possible choices for MC moves are translation of an atom, translation of a molecule, and rotation of a molecule. The relative amounts of each are determined by the optional \texttt{mcmoves} keyword (see below). The default behavior is as follows. If the \texttt{mol} keyword is used, only molecule translations and molecule rotations are performed with equal probability. Conversely, if the \texttt{mol} keyword is not used, only atom translations are performed. \(M\) should typically be chosen to be approximately equal to the expected number of gas atoms or molecules of the given type within the simulation cell or region, which will result in roughly one MC move per atom or molecule per MC cycle.

All inserted particles are always added to two groups: the default group “all” and the fix group specified in the fix command. In addition, particles are also added to any groups specified by the \texttt{group} and \texttt{grouptype} keywords. If
inserted particles are individual atoms, they are assigned the atom type given by the type argument. If they are molecules, the type argument has no effect and must be set to zero. Instead, the type of each atom in the inserted molecule is specified in the file read by the molecule command.

**Note:** Care should be taken to apply fix gcmc only to a group that contains only those atoms and molecules that you wish to manipulate using Monte Carlo. Hence it is generally not a good idea to specify the default group “all” in the fix command, although it is allowed.

This fix cannot be used to perform GCMC insertions of gas atoms or molecules other than the exchanged type, but GCMC deletions, and MC translations, and rotations can be performed on any atom/molecule in the fix group. All atoms in the simulation cell can be moved using regular time integration translations, e.g. via fix nvt, resulting in a hybrid GCMC+MD simulation. A smaller-than-usual timestep size may be needed when running such a hybrid simulation, especially if the inserted molecules are not well equilibrated.

This command may optionally use the region keyword to define an exchange and move volume. The specified region must have been previously defined with a region command. It must be defined with side = in. Insertion attempts occur only within the specified region. For non-rectangular regions, random trial points are generated within the rectangular bounding box until a point is found that lies inside the region. If no valid point is generated after 1000 trials, no insertion is performed, but it is counted as an attempted insertion. Move and deletion attempt candidates are selected from gas atoms or molecules within the region. If there are no candidates, no move or deletion is performed, but it is counted as an attempt move or deletion. If an attempted move places the atom or molecule center-of-mass outside the specified region, a new attempted move is generated. This process is repeated until the atom or molecule center-of-mass is inside the specified region.

If used with fix nvt, the temperature of the imaginary reservoir, T, should be set to be equivalent to the target temperature used in fix nvt. Otherwise, the imaginary reservoir will not be in thermal equilibrium with the simulation cell. Also, it is important that the temperature used by fix nvt be dynamic/dof, which can be achieved as follows:

```
compute mdtemp mdatoms temp
compute_modify mdtemp dynamic/dof yes
fix mdnvt mdatoms nvt temp 300.0 300.0 10.0
fix_modify mdnvt temp mdtemp
```

Note that neighbor lists are re-built every timestep that this fix is invoked, so you should not set N to be too small. However, periodic rebuilds are necessary in order to avoid dangerous rebuilds and missed interactions. Specifically, avoid performing so many MC translations per timestep that atoms can move beyond the neighbor list skin distance. See the neighbor command for details.

When an atom or molecule is to be inserted, its coordinates are chosen at a random position within the current simulation cell or region, and new atom velocities are randomly chosen from the specified temperature distribution given by T. The effective temperature for new atom velocities can be increased or decreased using the optional keyword tfac_insert (see below). Relative coordinates for atoms in a molecule are taken from the template molecule provided by the user. The center of mass of the molecule is placed at the insertion point. The orientation of the molecule is chosen at random by rotating about this point.

Individual atoms are inserted, unless the mol keyword is used. It specifies a template-ID previously defined using the molecule command, which reads a file that defines the molecule. The coordinates, atom types, charges, etc., as well as any bonding and special neighbor information for the molecule can be specified in the molecule file. See the molecule command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

When not using the mol keyword, you should ensure you do not delete atoms that are bonded to other atoms, or LAMMPS will soon generate an error when it tries to find bonded neighbors. LAMMPS will warn you if any of the atoms eligible for deletion have a non-zero molecule ID, but does not check for this at the time of deletion.

If you wish to insert molecules using the mol keyword that will be treated as rigid bodies, use the rigid keyword,
specifying as its value the ID of a separate `fix rigid/small` command which also appears in your input script.

**Note:** If you wish the new rigid molecules (and other rigid molecules) to be thermostatted correctly via `fix rigid/small/nvt` or `fix rigid/small/npt`, then you need to use the “fix_modify dynamic/dof yes” command for the rigid fix. This is to inform that fix that the molecule count will vary dynamically.

If you wish to insert molecules via the `mol` keyword, that will have their bonds or angles constrained via SHAKE, use the `shake` keyword, specifying as its value the ID of a separate `fix shake` command which also appears in your input script.

Optionally, users may specify the relative amounts of different MC moves using the `mcmoves` keyword. The values `Patomtrans`, `Pmoltrans`, `Pmolrotate` specify the average proportion of atom translations, molecule translations, and molecule rotations, respectively. The values must be non-negative integers or real numbers, with at least one non-zero value. For example, `(10,30,0)` would result in 25% of the MC moves being atomic translations, 75% molecular translations, and no molecular rotations.

Optionally, users may specify the maximum rotation angle for molecular rotations using the `maxangle` keyword and specifying the angle in degrees. Rotations are performed by generating a random point on the unit sphere and a random rotation angle on the range `[0,maxangle)`. The molecule is then rotated by that angle about an axis passing through the molecule center of mass. The axis is parallel to the unit vector defined by the point on the unit sphere. The same procedure is used for randomly rotating molecules when they are inserted, except that the maximum angle is 360 degrees.

Note that fix gcmc does not use configurational bias MC or any other kind of sampling of intramolecular degrees of freedom. Inserted molecules can have different orientations, but they will all have the same intramolecular configuration, which was specified in the molecule command input.

For atomic gasses, inserted atoms have the specified atom type, but deleted atoms are any atoms that have been inserted or that already belong to the fix group. For molecular gasses, exchanged molecules use the same atom types as in the template molecule supplied by the user. In both cases, exchanged atoms/molecules are assigned to two groups: the default group “all” and the fix group (which can also be “all”).

The chemical potential is a user-specified input parameter defined as:

$$\mu = \mu^{id} + \mu^{ex}$$

The second term $\mu_{ex}$ is the excess chemical potential due to energetic interactions and is formally zero for the fictitious gas reservoir but is non-zero for interacting systems. So, while the chemical potential of the reservoir and the simulation cell are equal, $\mu_{ex}$ is not, and as a result, the densities of the two are generally quite different. The first term $\mu_{id}$ is the ideal gas contribution to the chemical potential. $\mu_{id}$ can be related to the density or pressure of the fictitious gas reservoir by:

$$\mu^{id} = k T \ln \rho \Lambda^{3} = k T \ln \frac{\phi P \Lambda^{3}}{k T}$$

where $k$ is Boltzmann’s constant, $T$ is the user-specified temperature, $\rho$ is the number density, $P$ is the pressure, and $\phi$ is the fugacity coefficient. The constant $\Lambda$ is required for dimensional consistency. For all unit styles except $lj$ it is defined as the thermal de Broglie wavelength

$$\Lambda = \sqrt{\frac{\hbar^2}{2\pi mkT}}$$

where $\hbar$ is Planck’s constant, and $m$ is the mass of the exchanged atom or molecule. For unit style $lj$, $\Lambda$ is simply set to unity. Note that prior to March 2017, $\Lambda$ for unit style $lj$ was calculated using the above formula with $\hbar$ set to the rather specific value of 0.18292026. Chemical potential under the old definition can be converted to an equivalent value under the new definition by subtracting $3kT \ln(\Lambda_{old})$. 

1048 Chapter 18. Fixes
As an alternative to specifying $\mu$ directly, the ideal gas reservoir can be defined by its pressure $P$ using the *pressure* keyword, in which case the user-specified chemical potential is ignored. The user may also specify the fugacity coefficient $\phi$ using the *fugacity_coeff* keyword, which defaults to unity.

The *full_energy* option means that the fix calculates the total potential energy of the entire simulated system, instead of just the energy of the part that is changed. The total system energy before and after the proposed GCMC exchange or MC move is then used in the Metropolis criterion to determine whether or not to accept the proposed change. By default, this option is off, in which case only partial energies are computed to determine the energy difference due to the proposed change.

The *full_energy* option is needed for systems with complicated potential energy calculations, including the following:

- long-range electrostatics (kspace)
- many-body pair styles
- hybrid pair styles
- eam pair styles
- tail corrections
- need to include potential energy contributions from other fixes

In these cases, LAMMPS will automatically apply the *full_energy* keyword and issue a warning message.

When the *mol* keyword is used, the *full_energy* option also includes the intramolecular energy of inserted and deleted molecules, whereas this energy is not included when *full_energy* is not used. If this is not desired, the *intra_energy* keyword can be used to define an amount of energy that is subtracted from the final energy when a molecule is inserted, and subtracted from the initial energy when a molecule is deleted. For molecules that have a non-zero intramolecular energy, this will ensure roughly the same behavior whether or not the *full_energy* option is used.

Inserted atoms and molecules are assigned random velocities based on the specified temperature $T$. Because the relative velocity of all atoms in the molecule is zero, this may result in inserted molecules that are systematically too cold. In addition, the intramolecular potential energy of the inserted molecule may cause the kinetic energy of the molecule to quickly increase or decrease after insertion. The *tfac_insert* keyword allows the user to counteract these effects by changing the temperature used to assign velocities to inserted atoms and molecules by a constant factor. For a particular application, some experimentation may be required to find a value of $tfac_insert$ that results in inserted molecules that equilibrate quickly to the correct temperature.

Some fixes have an associated potential energy. Examples of such fixes include: *efield, gravity, addforce, langevin, restrain, temp/berendsen, temp/rescale*, and *wall fixes*. For that energy to be included in the total potential energy of the system (the quantity used when performing GCMC exchange and MC moves), you MUST enable the *fix_modify energy* option for that fix. The doc pages for individual *fix* commands specify if this should be done.

Use the *charge* option to insert atoms with a user-specified point charge. Note that doing so will cause the system to become non-neutral. LAMMPS issues a warning when using long-range electrostatics (kspace) with non-neutral systems. See the *compute group/group* documentation for more details about simulating non-neutral systems with kspace on.

Use of this fix typically will cause the number of atoms to fluctuate, therefore, you will want to use the *compute_modify dynamic/dof* command to insure that the current number of atoms is used as a normalizing factor each time temperature is computed. A simple example of this is:

\[ \text{compute_modify thermo_temp dynamic yes} \]

A more complicated example is listed earlier on this page in the context of NVT dynamics.

**Note:** If the density of the cell is initially very small or zero, and increases to a much larger density after a period of equilibration, then certain quantities that are only calculated once at the start (kspace parameters) may no longer be
accurate. The solution is to start a new simulation after the equilibrium density has been reached.

With some pair_styles, such as *Buckingham*, *Born-Mayer-Huggins* and *ReaxFF*, two atoms placed close to each other may have an arbitrary large, negative potential energy due to the functional form of the potential. While these unphysical configurations are inaccessible to typical dynamical trajectories, they can be generated by Monte Carlo moves. The *overlap_cutoff* keyword suppresses these moves by effectively assigning an infinite positive energy to all new configurations that place any pair of atoms closer than the specified overlap cutoff distance.

The *max* and *min* keywords allow for the restriction of the number of atoms in the simulation. They automatically reject all insertion or deletion moves that would take the system beyond the set boundaries. Should the system already be beyond the boundary, only moves that bring the system closer to the bounds may be accepted.

The *group* keyword adds all inserted atoms to the *group* of the group-ID value. The *grouptype* keyword adds all inserted atoms of the specified type to the *group* of the group-ID value.

### 18.52.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the fix to *binary restart files*. This includes information about the random number generator seed, the next timestep for MC exchanges, the number of MC step attempts and successes etc. See the *read_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** For this to work correctly, the timestep must **not** be changed after reading the restart with *reset_timestep*. The fix will try to detect it and stop with an error.

None of the *fix_modify* options are relevant to this fix.

This fix computes a global vector of length 8, which can be accessed by various *output commands*. The vector values are the following global cumulative quantities:

- 1 = translation attempts
- 2 = translation successes
- 3 = insertion attempts
- 4 = insertion successes
- 5 = deletion attempts
- 6 = deletion successes
- 7 = rotation attempts
- 8 = rotation successes

The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.
18.52.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Do not set “neigh_modify once yes” or else this fix will never be called. Reneighboring is required.

Can be run in parallel, but aspects of the GCMC part will not scale well in parallel. Only usable for 3D simulations.

When using fix gcmc in combination with fix shake or fix rigid, only GCMC exchange moves are supported, so the argument $M$ must be zero.

Note that very lengthy simulations involving insertions/deletions of billions of gas molecules may run out of atom or molecule IDs and trigger an error, so it is better to run multiple shorter-duration simulations. Likewise, very large molecules have not been tested and may turn out to be problematic.

Use of multiple fix gcmc commands in the same input script can be problematic if using a template molecule. The issue is that the user-referenced template molecule in the second fix gcmc command may no longer exist since it might have been deleted by the first fix gcmc command. An existing template molecule will need to be referenced by the user for each subsequent fix gcmc command.

18.52.6 Related commands

fix atom/swap, fix nvt, neighbor, fix deposit, fix evaporate, delete_atoms

18.52.7 Default

The option defaults are mol = no, maxangle = 10, overlap_cutoff = 0.0, fugacity_coeff = 1.0, intra_energy = 0.0, tfac_insert = 1.0. (Patomtrans, Pmoltrans, Pmolrotate) = (1, 0, 0) for mol = no and (0, 1, 1) for mol = yes. full_energy = no, except for the situations where full_energy is required, as listed above.

18.53 fix gld command

18.53.1 Syntax

```
fix ID group-ID gld Tstart Tstop N_k seed series c_1 tau_1 ... c_N_k tau_N_k keyword_values ...
```

- ID, group-ID are documented in fix command
- gld = style name of this fix command
- Tstart, Tstop = desired temperature at start/end of run (temperature units)
- N_k = number of terms in the Prony series representation of the memory kernel
- seed = random number seed to use for white noise (positive integer)
- series = ppronyn is presently the only available option
- c_k = the weight of the kth term in the Prony series (mass per time units)
- tau_k = the time constant of the kth term in the Prony series (time units)
• zero or more keyword/value pairs may be appended
  
  keyword = frozen or zero
  frozen value = no or yes
  no = initialize extended variables using values drawn from equilibrium distribution at \( T_{\text{start}} \)
  yes = initialize extended variables to zero (i.e., from equilibrium distribution at zero temperature)
  zero value = no or yes
  no = do not set total random force to zero
  yes = set total random force to zero

### 18.53.2 Examples

```plaintext

fix 3 rouse gld 7.355 7.355 4 48823 pprony 107.1 0.02415 186.0 0.04294 428.6 0.09661 1714 0.38643
```

### 18.53.3 Description

Applies Generalized Langevin Dynamics to a group of atoms, as described in \( \text{Baczewski} \). This is intended to model the effect of an implicit solvent with a temporally non-local dissipative force and a colored Gaussian random force, consistent with the Fluctuation-Dissipation Theorem. The functional form of the memory kernel associated with the temporally non-local force is constrained to be a Prony series.

**Note:** While this fix bears many similarities to \textit{fix langevin}, it has one significant difference. Namely, \textit{fix gld} performs time integration, whereas \textit{fix langevin} does NOT. To this end, the specification of another fix to perform time integration, such as \textit{fix nve}, is NOT necessary.

With this fix active, the force on the \( j \)th atom is given as

\[
F_j(t) = F_j^C(t) - \int_0^t \Gamma_j(t-s)v_j(s)\,ds + F_j^R(t)
\]

\[
\Gamma_j(t-s) = \sum_{k=1}^{N_k} \frac{c_k}{\tau_k} e^{-(t-s)/\tau_k}
\]

\[
\langle F_j^R(t), F_j^R(s) \rangle = k_B T \Gamma_j(t-s)
\]

Here, the first term is representative of all conservative (pairwise, bonded, etc) forces external to this fix, the second is the temporally non-local dissipative force given as a Prony series, and the third is the colored Gaussian random force.

The Prony series form of the memory kernel is chosen to enable an extended variable formalism, with a number of exemplary mathematical features discussed in \( \text{Baczewski} \). In particular, \( 3N_k \) extended variables are added to each atom, which effect the action of the memory kernel without having to explicitly evaluate the integral over time in the second term of the force. This also has the benefit of requiring the generation of uncorrelated random forces, rather than correlated random forces as specified in the third term of the force.

Presently, the Prony series coefficients are limited to being greater than or equal to zero, and the time constants are limited to being greater than zero. To this end, the value of series MUST be set to \textit{pprony}, for now. Future updates will allow for negative coefficients and other representations of the memory kernel. It is with these updates in mind that the series option was included.
The units of the Prony series coefficients are chosen to be mass per time to ensure that the numerical integration scheme stably approaches the Newtonian and Langevin limits. Details of these limits, and the associated numerical concerns are discussed in (Baczewski).

The desired temperature at each timestep is ramped from $T_{\text{start}}$ to $T_{\text{stop}}$ over the course of the next run.

The random # seed must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The keyword/value option pairs are used in the following ways.

The keyword frozen can be used to specify how the extended variables associated with the GLD memory kernel are initialized. Specifying no (the default), the initial values are drawn at random from an equilibrium distribution at $T_{\text{start}}$, consistent with the Fluctuation-Dissipation Theorem. Specifying yes, initializes the extended variables to zero.

The keyword zero can be used to eliminate drift due to the thermostat. Because the random forces on different atoms are independent, they do not sum exactly to zero. As a result, this fix applies a small random force to the entire system, and the center-of-mass of the system undergoes a slow random walk. If the keyword zero is set to yes, the total random force is set exactly to zero by subtracting off an equal part of it from each atom in the group. As a result, the center-of-mass of a system with zero initial momentum will not drift over time.

**18.53.4 Restart, fix_modify, output, run start/stop, minimize info**

The instantaneous values of the extended variables are written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

**18.53.5 Restrictions**

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

**18.53.6 Related commands**

fix langevin, fix viscous, pair_style dpd/tstat
18.53.7 Default

The option defaults are frozen = no, zero = no.

18.54 fix gle command

18.54.1 Syntax

```
fix ID id-group gle Ns Tstart Tstop seed Amatrix [noneq Cmatrix] [every stride]
```

• ID, group-ID are documented in `fix` command
• gle = style name of this fix command
• Ns = number of additional fictitious momenta
• Tstart, Tstop = temperature ramp during the run
• Amatrix = file to read the drift matrix A from
• seed = random number seed to use for generating noise (positive integer)
• zero or more keyword/value pairs may be appended

  keyword = noneq or every
  noneq Cmatrix = file to read the non-equilibrium covariance matrix
  every stride = apply the GLE once every time steps. Reduces the
  accuracy of the integration of the GLE, but has *no effect* on the accuracy
  of equilibrium sampling. It might change sampling properties when used together
  with noneq.

18.54.2 Examples

```
fix 3 boundary gle 6 300 300 31415 smart.A
fix 1 all gle 6 300 300 31415 qt-300k.A noneq qt-300k.C
```

18.54.3 Description

Apply a Generalized Langevin Equation (GLE) thermostat as described in (Ceriotti). The formalism allows one to obtain a number of different effects ranging from efficient sampling of all vibrational modes in the system to inexpensive (approximate) modelling of nuclear quantum effects. Contrary to `fix langevin`, this fix performs both thermostatting and evolution of the Hamiltonian equations of motion, so it should not be used together with `fix nve` – at least not on the same atom groups.

Each degree of freedom in the thermostatted group is supplemented with Ns additional degrees of freedom s, and the equations of motion become
where \( F \) is the physical force, \( A \) is the drift matrix (that generalizes the friction in Langevin dynamics), \( B \) is the diffusion term and \( dW/dt \) un-correlated Gaussian random forces. The \( A \) matrix couples the physical \((q,p)\) dynamics with that of the additional degrees of freedom, and makes it possible to obtain effectively a history-dependent noise and friction kernel.

The drift matrix should be given as an external file \( Afile \) as a \((Ns+1 \times Ns+1)\) matrix in inverse time units. Matrices that are optimal for a given application and the system of choice can be obtained from (GLE4MD).

Equilibrium sampling a temperature \( T \) is obtained by specifying the target value as the \( Tstart \) and \( Tstop \) arguments, so that the diffusion matrix that gives canonical sampling for a given \( A \) is computed automatically. However, the GLE framework also allow for non-equilibrium sampling, that can be used for instance to model inexpensively zero-point energy effects (Ceriotti2). This is achieved specifying the \texttt{noneq} keyword followed by the name of the file that contains the static covariance matrix for the non-equilibrium dynamics. Please note, that the covariance matrix is expected to be given in temperature units.

Since integrating GLE dynamics can be costly when used together with simple potentials, one can use the \texttt{every} optional keyword to apply the Langevin terms only once every several MD steps, in a multiple time-step fashion. This should be used with care when doing non-equilibrium sampling, but should have no effect on equilibrium averages when using canonical sampling.

The random number \texttt{seed} must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

Note also that the Generalized Langevin Dynamics scheme that is implemented by the \texttt{fix gld} scheme is closely related to the present one. In fact, it should be always possible to cast the Prony series form of the memory kernel used by GLD into an appropriate input matrix for \texttt{fix gle}. While the GLE scheme is more general, the form used by \texttt{fix gld} can be more directly related to the representation of an implicit solvent environment.

### 18.54.4 Restart, \texttt{fix_modify}, output, run \texttt{start/stop}, minimize info

The instantaneous values of the extended variables are written to \textit{binary restart files}. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior. Note however that you should use a different seed each time you restart, otherwise the same sequence of random numbers will be used each time, which might lead to stochastic synchronization and subtle artifacts in the sampling.

This fix can ramp its target temperature over multiple runs, using the \texttt{start} and \texttt{stop} keywords of the \texttt{run} command. See the \texttt{run} command for details of how to do this.

The \texttt{fix_modify energy} option is supported by this fix to add the energy change induced by Langevin thermostatting to the system’s potential energy as part of thermodynamic output.

This fix computes a global scalar which can be accessed by various \textit{output commands}. The scalar is the cumulative energy change due to this fix. The scalar value calculated by this fix is “extensive”.

18.54. \texttt{fix gle} command
18.54.5 Restrictions

The GLE thermostat in its current implementation should not be used with rigid bodies, SHAKE or RATTLE. It is expected that all the thermostatted degrees of freedom are fully flexible, and the sampled ensemble will not be correct otherwise.

In order to perform constant-pressure simulations please use `fix press/berendsen`, rather than `fix npt`, to avoid duplicate integration of the equations of motion.

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.55 fix gravity command

Accelerator Variants: gravity/omp, gravity/kk

18.55.1 Syntax

```plaintext
fix ID group gravity magnitude style args
```

- `ID, group` are documented in `fix` command
- `gravity` = style name of this fix command
- `magnitude` = size of acceleration (force/mass units)
- `magnitude` can be a variable (see below)
- `style` = `chute` or `spherical` or `gradient` or `vector`

- chute args = angle
  - angle = angle in +x away from −z or −y axis in 3d/2d (in degrees)
  - angle can be a variable (see below)
  
- spherical args = phi theta
  - phi = azimuthal angle from +x axis (in degrees)
  - theta = angle from +z or +y axis in 3d/2d (in degrees)
  - phi or theta can be a variable (see below)

- vector args = x y z
  - x y z = vector direction to apply the acceleration
  - x or y or z can be a variable (see below)
18.55.2 Examples

```plaintext
fix 1 all gravity 1.0 chute 24.0
fix 1 all gravity v_increase chute 24.0
fix 1 all gravity 1.0 spherical 0.0 -180.0
fix 1 all gravity 10.0 spherical v_phi v_theta
fix 1 all gravity 100.0 vector 1 1 0
```

18.55.3 Description

Impose an additional acceleration on each particle in the group. This fix is typically used with granular systems to include a “gravity” term acting on the macroscopic particles. More generally, it can represent any kind of driving field, e.g. a pressure gradient inducing a Poiseuille flow in a fluid. Note that this fix operates differently than the `fix addforce` command. The addforce fix adds the same force to each atom, independent of its mass. This command imparts the same acceleration to each atom (force/mass).

The magnitude of the acceleration is specified in force/mass units. For granular systems (LJ units) this is typically 1.0. See the `units` command for details.

Style `chute` is typically used for simulations of chute flow where the specified angle is the chute angle, with flow occurring in the +x direction. For 3d systems, the tilt is away from the z axis; for 2d systems, the tilt is away from the y axis.

Style `spherical` allows an arbitrary 3d direction to be specified for the acceleration vector. Phi and theta are defined in the usual spherical coordinates. Thus for acceleration acting in the -z direction, theta would be 180.0 (or -180.0). Theta = 90.0 and phi = -90.0 would mean acceleration acts in the -y direction. For 2d systems, phi is ignored and theta is an angle in the xy plane where theta = 0.0 is the y-axis.

Style `vector` imposes an acceleration in the vector direction given by (x,y,z). Only the direction of the vector is important; it’s length is ignored. For 2d systems, the z component is ignored.

Any of the quantities magnitude, angle, phi, theta, x, y, z which define the gravitational magnitude and direction, can be specified as an equal-style variable. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the quantity. You should insure that the variable calculates a result in the appropriate units, e.g. force/mass or degrees.

Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent gravitational field.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.
18.55.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the gravitational potential energy of the system to the system’s potential energy as part of thermodynamic output.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various output commands. This scalar is the gravitational potential energy of the particles in the defined field, namely mass * (g dot x) for each particles, where x and mass are the particles position and mass, and g is the gravitational field. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

thermo_modify press fxgREM_press
fix          fxgREM_all grem 502 -0.15 -80000 fxnvt

18.56.3 Description

This fix implements the molecular dynamics version of the generalized replica exchange method (gREM) originally developed by (Kim), which uses non-Boltzmann ensembles to sample over first order phase transitions. The is done by defining replicas with an enthalpy dependent effective temperature

\[ T_{\text{eff}} = \lambda + \eta(H - H_0) \]

with \( \eta \) negative and steep enough to only intersect the characteristic microcanonical temperature (\( T_\text{s} \)) of the system once, ensuring a unimodal enthalpy distribution in that replica. \( \lambda \) is the intercept and effects the generalized ensemble similar to how temperature effects a Boltzmann ensemble. \( H_0 \) is a reference enthalpy, and is typically set as the lowest desired sampled enthalpy. Further explanation can be found in our recent papers (Malolepsza).

This fix requires a Nose-Hoover thermostat fix reference passed to the grem as thermostat-ID. Two distinct temperatures exist in this generalized ensemble, the effective temperature defined above, and a kinetic temperature that controls the velocity distribution of particles as usual. Either constant volume or constant pressure algorithms can be used.

The fix enforces a generalized ensemble in a single replica only. Typically, this ideology is combined with replica exchange with replicas differing by \( \lambda \) only for simplicity, but this is not required. A multi-replica simulation can be run within the LAMMPS environment using the temper/grem command. This utilizes LAMMPS partition mode and requires the number of available processors be on the order of the number of desired replicas. A 100-replica simulation would require at least 100 processors (1 per world at minimum). If many replicas are needed on a small number of processors, multi-replica runs can be run outside of LAMMPS. An example of this can be found in examples/USER/misc/grem and has no limit on the number of replicas per processor. However, this is very inefficient and error prone and should be avoided if possible.

In general, defining the generalized ensembles is unique for every system. When starting a many-replica simulation without any knowledge of the underlying microcanonical temperature, there are several tricks we have utilized to optimize the process. Choosing a less-steep \( \eta \) yields broader distributions, requiring fewer replicas to map the microcanonical temperature. While this likely struggles from the same sampling problems gREM was built to avoid, it provides quick insight to \( T_\text{s} \). Initially using an evenly-spaced \( \lambda \) distribution identifies regions where small changes in enthalpy lead to large temperature changes. Replicas are easily added where needed.

18.56.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The thermo_modify press option is supported by this fix to add the rescaled kinetic pressure as part of thermodynamic output.
18.56.5 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.57 fix halt command

18.57.1 Syntax

| fix ID group-ID halt N attribute operator avalue keyword value |

- ID, group-ID are documented in fix command
- halt = style name of this fix command
- N = check halt condition every N steps
- attribute = bondmax or tlimit or v_name
  - bondmax = length of longest bond in the system (in length units)
  - tlimit = elapsed CPU time (in seconds)
  - diskfree = free disk space (in megabytes)
  - v_name = name of equal-style variable
- operator = “<” or “<=” or “>” or “>=” or “==” or “!=” or “^”
- avalue = numeric value to compare attribute to
- zero or more keyword/value pairs may be appended
- keyword = error or message or path
  - error value = hard or soft or continue
  - message value = yes or no
  - path value = path to check for free space (may be in quotes)
18.57.2 Examples

```plaintext
fix 10 all halt 1 bondmax > 1.5
fix 10 all halt 10 v_myCheck != 0 error soft
fix 10 all halt 100 diskfree < 100000.0 path "dump storage/.
```

18.57.3 Description

Check a condition every N steps during a simulation run. N must be >=1. If the condition is met, exit the run. In this context a “run” can be dynamics or minimization iterations, as specified by the run or minimize command.

The specified group-ID is ignored by this fix.

The specified attribute can be one of the options listed above, namely bondmax, tlimit, diskfree, or an equal-style variable referenced as v_name, where “name” is the name of a variable that has been defined previously in the input script.

The bondmax attribute will loop over all bonds in the system, compute their current lengths, and set attribute to the longest bond distance.

The tlimit attribute queries the elapsed CPU time (in seconds) since the current run began, and sets attribute to that value. This is an alternative way to limit the length of a simulation run, similar to the timer timeout command. There are two differences in using this method versus the timer command option. The first is that the clock starts at the beginning of the current run (not when the timer or fix command is specified), so that any setup time for the run is not included in the elapsed time. The second is that the timer invocation and syncing across all processors (via MPI_Allreduce) is not performed once every N steps by this command. Instead it is performed (typically) only a small number of times and the elapsed times are used to predict when the end-of-the-run will be. Both of these attributes can be useful when performing benchmark calculations for a desired length of time with minimal overhead. For example, if a run is performing 1000s of timesteps/sec, the overhead for syncing the timer frequently across a large number of processors may be non-negligible.

The diskfree attribute will check for available disk space (in megabytes) on supported operating systems. By default it will check the file system of the current working directory. This can be changed with the optional path keyword, which will take the path to a file or folder on the file system to be checked as argument. This path must be given with single or double quotes, if it contains blanks or other special characters (like $).

Equal-style variables evaluate to a numeric value. See the variable command for a description. They calculate formulas which can involve mathematical operations, atom properties, group properties, thermodynamic properties, global values calculated by a compute or fix, or references to other variables. Thus they are a very general means of computing some attribute of the current system. For example, the following “bondmax” variable will calculate the same quantity as the hstyle = bondmax option.

```plaintext
compute bdist all bond/local dist
compute bmax all reduce max c_bdist
variable bondmax equal c_bmax
```

Thus these two versions of a fix halt command will do the same thing:

```plaintext
fix 10 all halt 1 bondmax > 1.5
fix 10 all halt 1 v_bondmax > 1.5
```

The version with “bondmax” will just run somewhat faster, due to less overhead in computing bond lengths and not storing them in a separate compute.

The choice of operators listed above are the usual comparison operators. The XOR operation (exclusive or) is also included as “^”. In this context, XOR means that if either the attribute or avalue is 0.0 and the other is non-zero, then the result is “true”. Otherwise it is “false”.

18.57. fix halt command 1061
The specified *value* must be a numeric value.

The optional *error* keyword determines how the current run is halted. If its value is *hard*, then LAMMPS will stop with an error message.

If its value is *soft*, LAMMPS will exit the current run, but continue to execute subsequent commands in the input script. However, additional *run* or *minimize* commands will be skipped. For example, this allows a script to output the current state of the system, e.g. via a *write_dump* or *write_restart* command.

If its value is *continue*, the behavior is the same as for *soft*, except subsequent *run* or *minimize* commands are executed. This allows your script to remedy the condition that triggered the halt, if necessary. Note that you may wish use the *unfix* command on the fix halt ID, so that the same condition is not immediately triggered in a subsequent run.

The optional *message* keyword determines whether a message is printed to the screen and logfile when the halt condition is triggered. If *message* is set to *yes*, a one line message with the values that triggered the halt is printed. If *message* is set to *no*, no message is printed; the run simply exits. The latter may be desirable for post-processing tools that extract thermodynamic information from log files.

### 18.57.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

### 18.57.5 Restrictions

The *diskfree* attribute is currently only supported on Linux, MacOSX, and BSD.

### 18.57.6 Related commands

*variable*

### 18.57.7 Default

The option defaults are error = hard, message = yes, and path = “.”.

### 18.58 fix heat command

#### 18.58.1 Syntax

```
fix ID group-ID heat N eflux
```

- *ID, group-ID* are documented in *fix command*
- *heat* = style name of this fix command
- *N* = add/subtract heat every this many timesteps
- *eflux* = rate of heat addition or subtraction (energy/time units)
- *eflux* can be a variable (see below)
• zero or more keyword/value pairs may be appended to args

• keyword = region

  region value = region-ID
  region-ID = ID of region atoms must be in to have added force

18.58.2 Examples

```plaintext
fix 3 qin heat 1 1.0
fix 3 qin heat 10 v_flux
fix 4 qout heat 1 -1.0 region top
```

18.58.3 Description

Add non-translational kinetic energy (heat) to a group of atoms in a manner that conserves their aggregate momentum. Two of these fixes can be used to establish a temperature gradient across a simulation domain by adding heat (energy) to one group of atoms (hot reservoir) and subtracting heat from another (cold reservoir). E.g. a simulation sampling from the McDLT ensemble.

If the region keyword is used, the atom must be in both the group and the specified geometric region in order to have energy added or subtracted to it. If not specified, then the atoms in the group are affected wherever they may move to.

Heat addition/subtraction is performed every N timesteps.

The eflux parameter can be specified as a numeric constant or as an equal- or atom-style variable. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its current value(s) used to determine the flux.

If eflux is a numeric constant or equal-style variable which evaluates to a scalar value, then eflux determines the change in aggregate energy of the entire group of atoms per unit time, e.g. in eV/ps for metal units. In this case it is an “extensive” quantity, meaning its magnitude should be scaled with the number of atoms in the group. Note that since eflux also has per-time units (i.e. it is a flux), this means that a larger value of N will add/subtract a larger amount of energy each time the fix is invoked.

Note: The heat-exchange (HEX) algorithm implemented by this fix is known to exhibit a pronounced energy drift. An improved algorithm (eHEX) is available as a fix ehex command and might be preferable if energy conservation is important.

If eflux is specified as an atom-style variable (see below), then the variable computes one value per atom. In this case, each value is the energy flux for a single atom, again in units of energy per unit time. In this case, each value is an “intensive” quantity, which need not be scaled with the number of atoms in the group.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent flux.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent flux with optional time-dependence as well.

Note: If heat is subtracted from the system too aggressively so that the group’s kinetic energy would go to zero, or any individual atom’s kinetic energy would go to zero for the case where eflux is an atom-style variable, then LAMMPS will halt with an error message.
Fix heat is different from a thermostat such as fix nvt or fix temp/rescale in that energy is added/subtracted continually. Thus if there is not another mechanism in place to counterbalance this effect, the entire system will heat or cool continuously. You can use multiple heat fixes so that the net energy change is 0.0 or use fix viscous to drain energy from the system.

This fix does not change the coordinates of its atoms; it only scales their velocities. Thus you must still use an integration fix (e.g. fix nve) on the affected atoms. This fix should not normally be used on atoms that have their temperature controlled by another fix - e.g. fix nvt or fix langevin fix.

### 18.58.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes a global scalar which can be accessed by various output commands. This scalar is the most recent value by which velocities were scaled. The scalar value calculated by this fix is “intensive”. If eflux is specified as an atom-style variable, this fix computes the average value by which the velocities were scaled for all of the atoms that had their velocities scaled.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

### 18.59 fix hyper/global command

#### 18.59.1 Syntax

```
fix ID group-ID hyper/global cutbond qfactor Vmax Tequil
```

- ID, group-ID are documented in fix command
- hyper/global = style name of this fix command
- cutbond = max distance at which a pair of atoms is considered bonded (distance units)
- qfactor = max strain at which bias potential goes to 0.0 (unitless)
- Vmax = height of bias potential (energy units)
- Tequil = equilibration temperature (temperature units)
18.59.2 Examples

```
fix 1 all hyper/global 1.0 0.3 0.8 300.0
```

18.59.3 Description

This fix is meant to be used with the `hyper` command to perform a bond-boost global hyperdynamics (GHD) simulation. The role of this fix is to select a single pair of atoms in the system at each timestep to add a global bias potential to, which will alter the dynamics of the system in a manner that effectively accelerates time. This is in contrast to the `fix hyper/local` command, which can be used to perform a local hyperdynamics (LHD) simulation, by adding a local bias potential to multiple pairs of atoms at each timestep. GHD can time accelerate a small simulation with up to a few 100 atoms. For larger systems, LHD is needed to achieve good time acceleration.

For a system that undergoes rare transition events, where one or more atoms move over an energy barrier to a new potential energy basin, the effect of the bias potential is to induce more rapid transitions. This can lead to an overall increase in the elapsed real time of the simulation as compared to running for the same number of timesteps with normal MD. See the `hyper` doc page for a more general discussion of hyperdynamics and citations that explain both GHD and LHD.

The equations and logic used by this fix and described here to perform GHD follow the description given in (Voter2013). The bond-boost form of a bias potential for HD is due to Miron and Fichthorn as described in (Miron). In LAMMPS we use a simplified version of bond-boost GHD where a single bond in the system is biased at any one timestep.

Bonds are defined between each pair of atoms $ij$, whose $R_{ij}^0$ distance is less than `cutbond`, when the system is in a quenched state (minimum) energy. Note that these are not “bonds” in a covalent sense. A bond is simply any pair of atoms that meet the distance criterion. `Cutbond` is an argument to this fix; it is discussed below. A bond is only formed if one or both of the $ij$ atoms are in the specified group.

The current strain of bond $ij$ (when running dynamics) is defined as

$$E_{ij} = \frac{R_{ij} - R_{ij}^0}{R_{ij}^0}$$

where $R_{ij}$ is the current distance between atoms $i$ and $j$, and $R_{ij}^0$ is the equilibrium distance in the quenched state.

The bias energy $V_{ij}$ of any bond between atoms $i$ and $j$ is defined as

$$V_{ij} = V_{\text{max}} \cdot \left( 1 - \left( \frac{E_{ij}}{q} \right)^2 \right) \text{ for } |E_{ij}| < q \text{factor or } 0 \text{ otherwise}$$

where the prefactor $V_{\text{max}}$ and the cutoff $q \text{factor}$ are arguments to this fix; they are discussed below. This functional form is an inverse parabola centered at 0.0 with height $V_{\text{max}}$ and which goes to 0.0 at +/- $q \text{factor}$.

Let $E_{\text{max}}$ be the maximum of $|E_{ij}|$ for all $ij$ bonds in the system on a given timestep. On that step, $V_{ij}$ is added as a bias potential to only the single bond with strain $E_{\text{max}}$, call it $V^*_{ij}$. Note that $V^*_{ij}$ will be 0.0 if $E_{\text{max}} >= q \text{factor}$ on that timestep. Also note that $V^*_{ij}$ is added to the normal interatomic potential that is computed between all atoms in the system at every step.

The derivative of $V^*_{ij}$ with respect to the position of each atom in the $E_{\text{max}}$ bond gives a bias force $F^*_{ij}$ acting on the bond as

$$F^*_{ij} = -\frac{dV^*_{ij}}{dE_{ij}} = \frac{2V_{\text{max}} E_{ij}}{q \text{factor}^2} \text{ for } |E_{ij}| < q \text{factor or } 0 \text{ otherwise}$$

which can be decomposed into an equal and opposite force acting on only the two $ij$ atoms in the $E_{\text{max}}$ bond.
The time boost factor for the system is given each timestep \( I \) by

\[ B_i = e^{\beta V_{ij}^{\text{max}}} \]

where \( \beta = \frac{1}{k T_{\text{equil}}} \), and \( T_{\text{equil}} \) is the temperature of the system and an argument to this fix. Note that \( B_i \geq 1 \) at every step.

**Note:** To run a GHD simulation, the input script must also use the `fix langevin` command to thermostat the atoms at the same \( T_{\text{equil}} \) as specified by this fix, so that the system is running constant-temperature (NVT) dynamics. LAMMPS does not check that this is done.

The elapsed time \( t_{\text{hyper}} \) for a GHD simulation running for \( N \) timesteps is simply

\[ t_{\text{hyper}} = \sum_{i=1, N} B - i \cdot dt \]

where \( dt \) is the timestep size defined by the `timestep` command. The effective time acceleration due to GHD is thus \( t_{\text{hyper}} / N \cdot dt \), where \( N \cdot dt \) is elapsed time for a normal MD run of \( N \) timesteps.

Note that in GHD, the boost factor varies from timestep to timestep. Likewise, which bond has \( E_{\text{max}} \) strain and thus which pair of atoms the bias potential is added to, will also vary from timestep to timestep. This is in contrast to local hyperdynamics (LHD) where the boost factor is an input parameter; see the `fix hyper/local` doc page for details.

Here is additional information on the input parameters for GHD.

The `cutbond` argument is the cutoff distance for defining bonds between pairs of nearby atoms. A pair of \( ij \) atoms in their equilibrium, minimum-energy configuration, which are separated by a distance \( R_{ij} < \text{cutbond} \), are flagged as a bonded pair. Setting `cutbond` to be \(~25\%\) larger than the nearest-neighbor distance in a crystalline lattice is a typical choice for solids, so that bonds exist only between nearest neighbor pairs.

The `qfactor` argument is the limiting strain at which the bias potential goes to 0.0. It is dimensionless, so a value of 0.3 means a bond distance can be up to 30\% larger or 30\% smaller than the equilibrium (quenched) \( R_{0ij} \) distance and the two atoms in the bond could still experience a non-zero bias force.

If `qfactor` is set too large, then transitions from one energy basin to another are affected because the bias potential is non-zero at the transition state (e.g. saddle point). If `qfactor` is set too small than little boost is achieved because the \( E_{ij} \) strain of some bond in the system will (nearly) always exceed `qfactor`. A value of 0.3 for `qfactor` is typically reasonable.

The `Vmax` argument is the prefactor on the bias potential. Ideally, it should be set to a value slightly less than the smallest barrier height for an event to occur. Otherwise the applied bias potential may be large enough (when added to the interatomic potential) to produce a local energy basin with a maxima in the center. This can produce artificial energy minima in the same basin that trap an atom. Or if `Vmax` is even larger, it may induce an atom(s) to rapidly transition to another energy basin. Both cases are “bad dynamics” which violate the assumptions of GHD that guarantee an accelerated time-accurate trajectory of the system.

Note that if `Vmax` is set too small, the GHD simulation will run correctly. There will just be fewer events because the hyper time (\( t_{\text{hyper}} \) equation above) will be shorter.

**Note:** If you have no physical intuition as to the smallest barrier height in your system, a reasonable strategy to determine the largest `Vmax` you can use for a GHD model, is to run a sequence of simulations with smaller and smaller `Vmax` values, until the event rate does not change (as a function of hyper time).

The `Tequil` argument is the temperature at which the system is simulated; see the comment above about the `fix langevin` thermostating. It is also part of the beta term in the exponential factor that determines how much boost is achieved as a function of the bias potential.
In general, the lower the value of Tequil and the higher the value of Vmax, the more time boost will be achievable by the GHD algorithm.

18.59.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the energy of the bias potential to the system’s potential energy as part of thermodynamic output.

This fix computes a global scalar and global vector of length 12, which can be accessed by various output commands. The scalar is the magnitude of the bias potential (energy units) applied on the current timestep. The vector stores the following quantities:

- 1 = boost factor on this step (unitless)
- 2 = max strain $E_{ij}$ of any bond on this step (absolute value, unitless)
- 3 = ID of first atom in the max-strain bond
- 4 = ID of second atom in the max-strain bond
- 5 = average # of bonds/atom on this step
- 6 = fraction of timesteps where the biased bond has bias = 0.0 during this run
- 7 = fraction of timesteps where the biased bond has negative strain during this run
- 8 = max drift distance of any atom during this run (distance units)
- 9 = max bond length during this run (distance units)
- 10 = cumulative hyper time since fix was defined (time units)
- 11 = cumulative count of event timesteps since fix was defined
- 12 = cumulative count of atoms in events since fix was defined

The first 5 quantities are for the current timestep. Quantities 6-9 are for the current hyper run. They are reset each time a new hyper run is performed. Quantities 19-12 are cumulative across multiple runs (since the point in the input script the fix was defined).

For value 8, drift is the distance an atom moves between two quenched states when the second quench determines an event has occurred. Atoms involved in an event will typically move the greatest distance since others typically remain near their original quenched position.

For value 11, events are checked for by the hyper command once every $N_{event}$ timesteps. This value is the count of those timesteps on which one (or more) events was detected. It is NOT the number of distinct events, since more than one event may occur in the same $N_{event}$ time window.

For value 12, each time the hyper command checks for an event, it invokes a compute to flag zero or more atoms as participating in one or more events. E.g. atoms that have displaced more than some distance from the previous quench state. Value 11 is the cumulative count of the number of atoms participating in any of the events that were found.

The scalar and vector values calculated by this fix are all “intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
18.59.5 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

18.60.3 Description

This fix is meant to be used with the hyper command to perform a bond-boost local hyperdynamics (LHD) simulation. The role of this fix is to select multiple pairs of atoms in the system at each timestep to add a local bias potential to, which will alter the dynamics of the system in a manner that effectively accelerates time. This is in contrast to the fix hyper/global command, which can be used to perform a global hyperdynamics (GHD) simulation, by adding a global bias potential to a single pair of atoms at each timestep. GHD can time accelerate a small simulation with up to a few 100 atoms. For larger systems, LHD is needed to achieve good time acceleration.

For a system that undergoes rare transition events, where one or more atoms move over an energy barrier to a new potential energy basin, the effect of the bias potential is to induce more rapid transitions. This can lead to a dramatic speed-up in the rate at which events occur, without altering their relative frequencies, thus leading to an overall increase in the elapsed real time of the simulation as compared to running for the same number of timesteps with normal MD. See the hyper doc page for a more general discussion of hyperdynamics and citations that explain both GHD and LHD.

The equations and logic used by this fix and described here to perform LHD follow the description given in (Voter2013). The bond-boost form of a bias potential for HD is due to Miron and Fichthorn as described in (Miron).

To understand this description, you should first read the description of the GHD algorithm on the fix hyper/global doc page. This description of LHD builds on the GHD description.

The definition of bonds and $E_{ij}$ are the same for GHD and LHD. The formulas for $V_{ij}^{max}$ and $F_{ij}^{max}$ are also the same except for a pre-factor $C_{ij}$, explained below.

The bias energy $V_{ij}$ applied to a bond $ij$ with maximum strain is

$$V_{ij}^{max} = C_{ij} \cdot V_{max} \cdot \left(1 - \left(\frac{E_{ij}}{q}\right)^2\right) \text{ for } |E_{ij}| < qfactor \text{ or } 0 \text{ otherwise}$$

The derivative of $V_{ij}^{max}$ with respect to the position of each atom in the $ij$ bond gives a bias force $F_{ij}^{max}$ acting on the bond as

$$F_{ij}^{max} = \frac{dV_{ij}^{max}}{dE_{ij}} = 2C_{ij}V_{max}E_{ij} qfactor^2 \text{ for } |E_{ij}| < qfactor \text{ or } 0 \text{ otherwise}$$

which can be decomposed into an equal and opposite force acting on only the two atoms $i$ and $j$ in the $ij$ bond.

The key difference is that in GHD a bias energy and force is added (on a particular timestep) to only one bond (pair of atoms) in the system, which is the bond with maximum strain $E_{max}$.

In LHD, a bias energy and force can be added to multiple bonds separated by the specified $Dcut$ distance or more. A bond $ij$ is biased if it is the maximum strain bond within its local “neighborhood”, which is defined as the bond $ij$ plus any neighbor bonds within a distance $Dcut$ from $ij$. The “distance” between bond $ij$ and bond $kl$ is the minimum distance between any of the $ik$, $il$, $jk$, and $jl$ pairs of atoms.

For a large system, multiple bonds will typically meet this requirement, and thus a bias potential $V_{ij}^{max}$ will be applied to many bonds on the same timestep.

In LHD, all bonds store a $C_{ij}$ prefactor which appears in the $V_{ij}^{max}$ and $F_{ij}^{max}$ equations above. Notethatthe : math : factor scales the strength of the bias energy and forces whenever bond $ij$ is the maximum strain bond in its neighborhood.
$C_{ij}$ is initialized to 1.0 when a bond between the $ij$ atoms is first defined. The specified $B_{\text{target}}$ factor is then used to adjust the $C_{ij}$ prefactors for each bond every timestep in the following manner.

An instantaneous boost factor $B_{ij}$ is computed each timestep for each bond, as

$$B_{ij} = e^{\beta V_{\text{max}}^{ij}}$$

where $V_{\text{max}}^{ij}$ is the bias energy of the maxstrain bond $kl$ within bond $ij$’s neighborhood, $\beta = \frac{1}{k_B T_{\text{equil}}}$, and $T_{\text{equil}}$ is the temperature of the system and an argument to this fix.

Note: To run an LHD simulation, the input script must also use the fix langevin command to thermostat the atoms at the same $T_{\text{equil}}$ as specified by this fix, so that the system is running constant-temperature (NVT) dynamics. LAMMPS does not check that this is done.

Note that if $ij = kl$, then bond $ij$ is a biased bond on that timestep, otherwise it is not. But regardless, the boost factor $B_{ij}$ can be thought of an estimate of time boost currently being applied within a local region centered on bond $ij$. For LHD, we want this to be the specified $B_{\text{target}}$ value everywhere in the simulation domain.

To accomplish this, if $B_{ij} < B_{\text{target}}$, the $C_{ij}$ prefactor for bond $ij$ is incremented on the current timestep by an amount proportional to the inverse of the specified $\alpha$ and the difference ($B_{ij} - B_{\text{target}}$). Conversely if $B_{ij} > B_{\text{target}}$, $C_{ij}$ is decremented by the same amount. This procedure is termed “boostostatting” in (Voter2013). It drives all of the individual $C_{ij}$ to values such that when $V_{\text{max}}^{ij}$ is applied as a bias to bond $ij$, the resulting boost factor $B_{ij}$ will be close to $B_{\text{target}}$ on average. Thus the LHD time acceleration factor for the overall system is effectively $B_{\text{target}}$.

Note that in LHD, the boost factor $B_{\text{target}}$ is specified by the user. This is in contrast to global hyperdynamics (GHD) where the boost factor varies each timestep and is computed as a function of $V_{\text{max}}$, $E_{\text{max}}$, and $T_{\text{equil}}$; see the fix hyper/global doc page for details.

Here is additional information on the input parameters for LHD.

Note that the cutbond, qfactor, and Tequil arguments have the same meaning as for GHD. The Vmax argument is slightly different. The Deut, alpha, and Btarget parameters are unique to LHD.

The cutbond argument is the cutoff distance for defining bonds between pairs of nearby atoms. A pair of I,J atoms in their equilibrium, minimum-energy configuration, which are separated by a distance $R_{ij} < \text{cutbond}$, are flagged as a bonded pair. Setting cutbond to be ~25% larger than the nearest-neighbor distance in a crystalline lattice is a typical choice for solids, so that bonds exist only between nearest neighbor pairs.

The qfactor argument is the limiting strain at which the bias potential goes to 0.0. It is dimensionless, so a value of 0.3 means a bond distance can be up to 30% larger or 30% smaller than the equilibrium (quenched) $R_{ij}^0$ distance and the two atoms in the bond could still experience a non-zero bias force.

If qfactor is set too large, then transitions from one energy basin to another are affected because the bias potential is non-zero at the transition state (e.g. saddle point). If qfactor is set too small than little boost can be achieved because the $E_{ij}$ strain of some bond in the system will (nearly) always exceed qfactor. A value of 0.3 for qfactor is typically a reasonable value.

The Vmax argument is a fixed prefactor on the bias potential. There is a also a dynamic prefactor $C_{ij}$, driven by the choice of Btarget as discussed above. The product of these should be a value less than the smallest barrier height for an event to occur. Otherwise the applied bias potential may be large enough (when added to the interatomic potential) to produce a local energy basin with a maxima in the center. This can produce artificial energy minima in the same basin that trap an atom. Or if $C_{ij} \cdot V_{\text{max}}^{ij}$ is even larger, it may induce an atom(s) to rapidly transition to another energy basin. Both cases are “bad dynamics” which violate the assumptions of LHD that guarantee an accelerated time-accurate trajectory of the system.
**Note:** It may seem that \( V_{\max} \) can be set to any value, and \( C_{ij} \) will compensate to reduce the overall prefactor if necessary. However the \( C_{ij} \) are initialized to 1.0 and the booststatting procedure typically operates slowly enough that there can be a time period of bad dynamics if \( V_{\max} \) is set too large. A better strategy is to set \( V_{\max} \) to the slightly smaller than the lowest barrier height for an event (the same as for GHD), so that the \( C_{ij} \) remain near unity.

The *Tequil* argument is the temperature at which the system is simulated; see the comment above about the *fix langevin* thermostatting. It is also part of the beta term in the exponential factor that determines how much boost is achieved as a function of the bias potential. See the discussion of the *Btarget* argument below.

As discussed above, the *Dcut* argument is the distance required between two locally maxstrain bonds for them to both be selected as biased bonds on the same timestep. Computationally, the larger *Dcut* is, the more work (computation and communication) must be done each timestep within the LHD algorithm. And the fewer bonds can be simultaneously biased, which may mean the specified *Btarget* time acceleration cannot be achieved.

Physically *Dcut* should be a long enough distance that biasing two pairs of atoms that close together will not influence the dynamics of each pair. E.g. something like 2x the cutoff of the interatomic potential. In practice a *Dcut* value of \(~10\) Angstroms seems to work well for many solid-state systems.

**Note:** You should insure that ghost atom communication is performed for a distance of at least \( D_{\text{cut}} + c_{\text{event}} \) = the distance one or more atoms move (between quenched states) to be considered an “event”. It is an argument to the “compute event/displace” command used to detect events. By default the ghost communication distance is set by the pair_style cutoff, which will typically be < *Dcut*. The *comm_modify cutoff* command should be used to override the ghost cutoff explicitly, e.g.

```
comm_modify cutoff 12.0
```

Note that this fix does not know the *cutevent* parameter, but uses half the *cutbond* parameter as an estimate to warn if the ghost cutoff is not long enough.

As described above the *alpha* argument is a pre-factor in the booststat update equation for each bond’s \( C_{ij} \) prefactor. *Alpha* is specified in time units, similar to other thermostat or barostat damping parameters. It is roughly the physical time it will take the booststat to adjust a \( C_{ij} \) value from a too high (or too low) value to a correct one. An *alpha* setting of a few ps is typically good for solid-state systems. Note that the *alpha* argument here is the inverse of the *alpha* parameter discussed in (Voter2013).

The *Btarget* argument is the desired time boost factor (a value > 1) that all the atoms in the system will experience. The elapsed time \( t_{\text{hyper}} \) for an LHD simulation running for \( N \) timesteps is simply

\[
 t_{\text{hyper}} = B_{\text{target}} \cdot N \cdot dt
\]

where \( dt \) is the timestep size defined by the *timestep* command. The effective time acceleration due to LHD is thus

\[
 \frac{t_{\text{hyper}}}{N \cdot dt} = B_{\text{target}}, \quad \text{where} \quad N \cdot dt \quad \text{is the elapsed time for a normal MD run of} \quad N \text{ timesteps.}
\]

You cannot choose an arbitrarily large setting for *Btarget*. The maximum value you should choose is

\[
 B_{\text{target}} = e^{\beta V_{\text{small}}}
\]

where \( V_{\text{small}} \) is the smallest event barrier height in your system, \( \beta = \frac{1}{kT_{\text{equil}}} \), and \( T_{\text{equil}} \) is the specified temperature of the system (both by this fix and the Langevin thermostat).

Note that if *Btarget* is set smaller than this, the LHD simulation will run correctly. There will just be fewer events because the hyper time (\( t_{\text{hyper}} \) equation above) will be shorter.

**Note:** If you have no physical intuition as to the smallest barrier height in your system, a reasonable strategy to
determine the largest $B_{\text{target}}$ you can use for an LHD model, is to run a sequence of simulations with smaller and smaller $B_{\text{target}}$ values, until the event rate does not change (as a function of hyper time).

Here is additional information on the optional keywords for this fix.

The **bound** keyword turns on min/max bounds for bias coefficients $C_{ij}$ for all bonds. $C_{ij}$ is a prefactor for each bond on the bias potential of maximum strength $V_{\text{max}}$. Depending on the choice of $\alpha$ and $B_{\text{target}}$ and $V_{\text{max}}$, the boostostatting can cause individual $C_{ij}$ values to fluctuate. If the fluctuations are too large $C_{ij} \cdot V_{\text{max}}$ can exceed low barrier heights and induce bad event dynamics. Bounding the $C_{ij}$ values is a way to prevent this. If $B_{\text{frac}}$ is set to -1 or any negative value (the default) then no bounds are enforced on $C_{ij}$ values (except they must always be $\geq 0.0$). A $B_{\text{frac}}$ setting $\geq 0.0$ sets a lower bound of $1.0 - B_{\text{frac}}$ and upper bound of $1.0 + B_{\text{frac}}$ on each $C_{ij}$ value. Note that all $C_{ij}$ values are initialized to 1.0 when a bond is created for the first time. Thus $B_{\text{frac}}$ limits the bias potential height to $V_{\text{max}} + /- B_{\text{frac}} \cdot V_{\text{max}}$.

The **reset** keyword allows $V_{\text{max}}$ to be adjusted dynamically depending on the average value of all $C_{ij}$ prefactors. This can be useful if you are unsure what value of $V_{\text{max}}$ will match the $B_{\text{target}}$ boost for the system. The $C_{ij}$ values will then adjust in aggregate (up or down) so that $C_{ij} \cdot V_{\text{max}}$ produces a boost of $B_{\text{target}}$, but this may conflict with the **bound** keyword settings. By using **bound** and **reset** together, $V_{\text{max}}$ itself can be reset, and desired bounds still applied to the $C_{ij}$ values.

A setting for $R_{\text{freq}}$ of -1 (the default) means $V_{\text{max}}$ never changes. A setting of 0 means $V_{\text{max}}$ is adjusted every time an event occurs and bond pairs are recalculated. A setting of $N > 0$ timesteps means $V_{\text{max}}$ is adjusted on the first time an event occurs on a timestep $\geq N$ steps after the previous adjustment. The adjustment to $V_{\text{max}}$ is computed as follows. The current average of all $C_{ij} \cdot V_{\text{max}}$ values is computed and the $V_{\text{max}}$ is reset to that value. All $C_{ij}$ values are changed to new prefactors such the new $C_{ij} \cdot V_{\text{max}}$ is the same as it was previously. If the **bound** keyword was used, those bounds are enforced on the new $C_{ij}$ values. Henceforth, new bonds are assigned a $C_{ij} = 1.0$, which means their bias potential magnitude is the new $V_{\text{max}}$.

The **check/ghost** keyword turns on extra computation each timestep to compute statistics about ghost atoms used to determine which bonds to bias. The output of these stats are the vector values 14 and 15, described below. If this keyword is not enabled, the output of the stats will be zero.

The **check/bias** keyword turns on extra computation and communication to check if any biased bonds are closer than $D_{\text{cut}}$ to each other, which should not be the case if LHD is operating correctly. Thus it is a debugging check. The $Nevery$ setting determines how often the check is made. The $\text{error}$, $\text{warn}$, or $\text{ignore}$ setting determines what is done if the count of too-close bonds is not zero. Either the code will exit, or issue a warning, or silently tally the count. The count can be output as vector value 17, as described below. If this keyword is not enabled, the output of that statistic will be 0.

Note that both of these computations are costly, hence they are only enabled by these keywords.

### 18.60.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The **fix_modify energy** option is supported by this fix to add the energy of the bias potential to the system’s potential energy as part of thermodynamic output.

This fix computes a global scalar and global vector of length 28, which can be accessed by various output commands. The scalar is the magnitude of the bias potential (energy units) applied on the current timestep, summed over all biased bonds. The vector stores the following quantities:

- 1 = average boost for all bonds on this step (unitless)
• 2 = # of biased bonds on this step
• 3 = max strain $E_{ij}$ of any bond on this step (absolute value, unitless)
• 4 = value of $V_{max}$ on this step (energy units)
• 5 = average bias coeff for all bonds on this step (unitless)
• 6 = min bias coeff for all bonds on this step (unitless)
• 7 = max bias coeff for all bonds on this step (unitless)
• 8 = average # of bonds/atom on this step
• 9 = average neighbor bonds/bond on this step within $D_{cut}$
• 10 = average boost for all bonds during this run (unitless)
• 11 = average # of biased bonds/step during this run
• 12 = fraction of biased bonds with no bias during this run
• 13 = fraction of biased bonds with negative strain during this run
• 14 = max bond length during this run (distance units)
• 15 = average bias coeff for all bonds during this run (unitless)
• 16 = min bias coeff for any bond during this run (unitless)
• 17 = max bias coeff for any bond during this run (unitless)
• 18 = max drift distance of any bond atom during this run (distance units)
• 19 = max distance from proc subbox of any ghost atom with max strain $< q_{factor}$ during this run (distance units)
• 20 = max distance outside my box of any ghost atom with any max strain during this run (distance units)
• 21 = count of ghost atoms that could not be found on reneighbor steps during this run
• 22 = count of bias overlaps ($< D_{cut}$) found during this run
• 23 = cumulative hyper time since fix created (time units)
• 24 = cumulative count of event timesteps since fix created
• 25 = cumulative count of atoms in events since fix created
• 26 = cumulative # of new bonds formed since fix created

27 = average boost for biased bonds on this step (unitless) 28 = # of bonds with absolute strain $>= q$ on this step

The first quantities 1-9 are for the current timestep. Quantities 10-22 are for the current hyper run. They are reset each
time a new hyper run is performed. Quantities 23-26 are cumulative across multiple runs (since the point in the input
script the fix was defined).

For value 10, each bond instantaneous boost factor is given by the equation for $B_{ij}$ above. The total system boost
(average across all bonds) fluctuates, but should average to a value close to the specified $B_{target}$.

For value 12, the numerator is a count of all biased bonds on each timestep whose bias energy = 0.0 due to $E_{ij} >=
q_{factor}$. The denominator is the count of all biased bonds on all timesteps.

For value 13, the numerator is a count of all biased bonds on each timestep with negative strain. The denominator is
the count of all biased bonds on all timesteps.

Values 18-22 are mostly useful for debugging and diagnostic purposes.
For value 18, drift is the distance an atom moves between two quenched states when the second quench determines an event has occurred. Atoms involved in an event will typically move the greatest distance since others typically remain near their original quenched position.

For values 19-21, neighbor atoms in the full neighbor list with cutoff $D_{cut}$ may be ghost atoms outside a processor’s sub-box. Before the next event occurs they may move further than $D_{cut}$ away from the sub-box boundary. Value 19 is the furthest (from the sub-box) any ghost atom in the neighbor list with maxstrain < $q_{factor}$ was accessed during the run. Value 20 is the same except that the ghost atom’s maxstrain may be $\geq q_{factor}$, which may mean it is about to participate in an event. Value 21 is a count of how many ghost atoms could not be found on reneighbor steps, presumably because they moved too far away due to their participation in an event (which will likely be detected at the next quench).

Typical values for 19 and 20 should be slightly larger than $D_{cut}$, which accounts for ghost atoms initially at a $D_{cut}$ distance moving thermally before the next event takes place.

Note that for values 19 and 20 to be computed, the optional keyword check/ghost must be specified. Otherwise these values will be zero. This is because computing them incurs overhead, so the values are only computed if requested.

Value 21 should be zero or small. As explained above a small count likely means some ghost atoms were participating in their own events and moved a longer distance. If the value is large, it likely means the communication cutoff for ghosts is too close to $D_{cut}$ leading to many not-found ghost atoms before the next event. This may lead to a reduced number of bonds being selected for biasing, since the code assumes those atoms are part of highly strained bonds. As explained above, the comm_modify cutoff command can be used to set a longer cutoff.

For value 22, no two bonds should be biased if they are within a $D_{cut}$ distance of each other. This value should be zero, indicating that no pair of biased bonds are closer than $D_{cut}$ from each other.

Note that for value 22 to be computed, the optional keyword check/bias must be specified and it determines how often this check is performed. This is because performing the check incurs overhead, so if only computed as often as requested.

The result at the end of the run is the cumulative total from every timestep the check was made. Note that the value is a count of atoms in bonds which found other atoms in bonds too close, so it is almost always an over-count of the number of too-close bonds.

Value 23 is simply the specified boost factor times the number of timesteps times the timestep size.

For value 24, events are checked for by the hyper command once every $N_{event}$ timesteps. This value is the count of those timesteps on which one (or more) events was detected. It is NOT the number of distinct events, since more than one event may occur in the same $N_{event}$ time window.

For value 25, each time the hyper command checks for an event, it invokes a compute to flag zero or more atoms as participating in one or more events. E.g. atoms that have displaced more than some distance from the previous quench state. Value 25 is the cumulative count of the number of atoms participating in any of the events that were found.

Value 26 tallies the number of new bonds created by the bond reset operation. Bonds between a specific I,J pair of atoms may persist for the entire hyperdynamics simulation if neither I or J are involved in an event.

Value 27 computes the average boost for biased bonds only on this step.

Value 28 is the count of bonds with an absolute value of strain $\geq q$ on this step.

The scalar and vector values calculated by this fix are all “intensive”.

This fix also computes a local vector of length the number of bonds currently in the system. The value for each bond is its $C_{ij}$ prefactor (bias coefficient). These values can be can be accessed by various output commands. A particularly useful one is the fix ave/histo command which can be used to histogram the $C_{ij}$ values to see if they are distributed reasonably close to 1.0, which indicates a good choice of $V_{max}$.

The local values calculated by this fix are unitless.
No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during \textit{energy minimization}.

\subsection*{18.60.5 Restrictions}
This fix is part of the REPLICA package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

\subsection*{18.60.6 Related commands}
\textit{hyper, fix hyper/global}

\subsection*{18.60.7 Default}
The default settings for optimal keywords are \texttt{bounds} = -1 and \texttt{reset} = -1. The check/ghost and check/bias keywords are not enabled by default.

\section*{18.61 \texttt{fix imd} command}

\subsection*{18.61.1 Syntax}

\begin{verbatim}
fix ID group-ID imd trate port keyword values ...
\end{verbatim}

- \texttt{ID, group-ID} are documented in \textit{fix} command
- \texttt{imd} = style name of this fix command
- \texttt{port} = port number on which the fix listens for an IMD client
- \texttt{keyword = unwrap or fscale or trate}

\texttt{unwrap arg = on or off}
- \texttt{off} = coordinates are wrapped back into the principal unit cell \textsuperscript{\leftarrow} (default)
- \texttt{on} = "unwrapped" coordinates using the image flags used

\texttt{fscale arg = factor}
- \texttt{factor} = floating point number to scale IMD forces (default: 1.0)

\texttt{trate arg = transmission rate of coordinate data sets (default: 1)}

\texttt{nowait arg = on or off}
- \texttt{off} = LAMMPS waits to be connected to an IMD client before continuing \textsuperscript{\leftarrow} (default)
- \texttt{on} = LAMMPS listens for an IMD client, but continues with the run
18.61.2 Examples

```plaintext
fix vmd all imd 5678
fix comm all imd 8888 trate 5 unwrap on fscale 10.0
```

18.61.3 Description

This fix implements the “Interactive MD” (IMD) protocol which allows realtime visualization and manipulation of MD simulations through the IMD protocol, as initially implemented in VMD and NAMD. Specifically it allows LAMMPS to connect an IMD client, for example the VMD visualization program, so that it can monitor the progress of the simulation and interactively apply forces to selected atoms.

If LAMMPS is compiled with the pre-processor flag -DLAMMPS_ASYNC_IMD then fix imd will use POSIX threads to spawn a IMD communication thread on MPI rank 0 in order to offload data reading and writing from the main execution thread and potentially lower the inferred latencies for slow communication links. This feature has only been tested under linux.

There are example scripts for using this package with LAMMPS in examples/USER/imd. Additional examples and a driver for use with the Novint Falcon game controller as haptic device can be found at: http://sites.google.com/site/akohlmey/software/vrpn-icms.

The source code for this fix includes code developed by the Theoretical and Computational Biophysics Group in the Beckman Institute for Advanced Science and Technology at the University of Illinois at Urbana-Champaign. We thank them for providing a software interface that allows codes like LAMMPS to hook to VMD.

Upon initialization of the fix, it will open a communication port on the node with MPI task 0 and wait for an incoming connection. As soon as an IMD client is connected, the simulation will continue and the fix will send the current coordinates of the fix’s group to the IMD client at every trate MD step. When using r-RESPA, trate applies to the steps of the outmost RESPA level. During a run with an active IMD connection also the IMD client can request to apply forces to selected atoms of the fix group.

The port number selected must be an available network port number. On many machines, port numbers < 1024 are reserved for accounts with system manager privilege and specific applications. If multiple imd fixes would be active at the same time, each needs to use a different port number.

The nowait keyword controls the behavior of the fix when no IMD client is connected. With the default setting of off, LAMMPS will wait until a connection is made before continuing with the execution. Setting nowait to on will have the LAMMPS code be ready to connect to a client, but continue with the simulation. This can for example be used to monitor the progress of an ongoing calculation without the need to be permanently connected or having to download a trajectory file.

The trate keyword allows to select how often the coordinate data is sent to the IMD client. It can also be changed on request of the IMD client through an IMD protocol message. The unwrap keyword allows to send “unwrapped” coordinates to the IMD client that undo the wrapping back of coordinates into the principle unit cell, as done by default in LAMMPS. The fscale keyword allows to apply a scaling factor to forces transmitted by the IMD client. The IMD protocols stipulates that forces are transferred in kcal/mol/angstrom under the assumption that coordinates are given in angstrom. For LAMMPS runs with different units or as a measure to tweak the forces generated by the manipulation of the IMD client, this option allows to make adjustments.

To connect VMD to a listening LAMMPS simulation on the same machine with fix imd enabled, one needs to start VMD and load a coordinate or topology file that matches the fix group. When the VMD command prompts appears, one types the command line:

```
imd connect localhost 5678
```

This assumes that fix imd was started with 5678 as a port number for the IMD protocol.
The steps to do interactive manipulation of a running simulation in VMD are the following:

In the Mouse menu of the VMD Main window, select “Mouse -> Force -> Atom”. You may alternately select “Residue”, or “Fragment” to apply forces to whole residues or fragments. Your mouse can now be used to apply forces to your simulation. Click on an atom, residue, or fragment and drag to apply a force. Click quickly without moving the mouse to turn the force off. You can also use a variety of 3D position trackers to apply forces to your simulation. Game controllers or haptic devices with force-feedback such as the Novint Falcon or Sensable PHANTOM allow you to feel the resistance due to inertia or interactions with neighbors that the atoms experience you are trying to move, as if they were real objects. See the VMD IMD Homepage and the VRPN-ICMS Homepage for more details.

If IMD control messages are received, a line of text describing the message and its effect will be printed to the LAMMPS output screen, if screen output is active.

18.61.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global scalar or vector or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.61.5 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

When used in combination with VMD, a topology or coordinate file has to be loaded, which matches (in number and ordering of atoms) the group the fix is applied to. The fix internally sorts atom IDs by ascending integer value; in VMD (and thus the IMD protocol) those will be assigned 0-based consecutive index numbers.

When using multiple active IMD connections at the same time, each needs to use a different port number.

fix 1 all indent 10.0 sphere v_x v_y 0.0 v_radius side in
fix 2 flow indent 10.0 cylinder z 0.0 0.0 10.0 units box

18.62.3 Description

Insert an indenter within a simulation box. The indenter repels all atoms in the group that touch it, so it can be used to push into a material or as an obstacle in a flow. Or it can be used as a constraining wall around a simulation; see the discussion of the side keyword below.

The indenter can either be spherical or cylindrical or planar. You must set one of those 3 keywords.

A spherical indenter exerts a force of magnitude

\[ F(r) = -K (r - R)^2 \]

on each atom where \( K \) is the specified force constant, \( r \) is the distance from the atom to the center of the indenter, and \( R \) is the radius of the indenter. The force is repulsive and \( F(r) = 0 \) for \( r > R \).

A cylindrical indenter exerts the same force, except that \( r \) is the distance from the atom to the center axis of the cylinder. The cylinder extends infinitely along its axis.

Spherical and cylindrical indenters account for periodic boundaries in two ways. First, the center point of a spherical indenter \((x,y,z)\) or axis of a cylindrical indenter \((c1,c2)\) is remapped back into the simulation box, if the box is periodic in a particular dimension. This occurs every timestep if the indenter geometry is specified with a variable (see below), e.g. it is moving over time. Second, the calculation of distance to the indenter center or axis accounts for periodic boundaries. Both of these mean that an indenter can effectively move through and straddle one or more periodic boundaries.
A planar indenter is really an axis-aligned infinite-extent wall exerting the same force on atoms in the system, where $R$ is the position of the plane and $r-R$ is the distance from the plane. If the side parameter of the plane is specified as lo then it will indent from the lo end of the simulation box, meaning that atoms with a coordinate less than the plane’s current position will be pushed towards the hi end of the box and atoms with a coordinate higher than the plane’s current position will feel no force. Vice versa if side is specified as hi.

Any of the 4 quantities defining a spherical indenter’s geometry can be specified as an equal-style variable, namely x, y, z, or R. Similarly, for a cylindrical indenter, any of c1, c2, or R, can be a variable. For a planar indenter, pos can be a variable. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to define the indenter geometry.

Note that equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify indenter properties that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the start and stop keywords of the run command and the elaplong keyword of thermo_style custom for details.

For example, if a spherical indenter’s x-position is specified as v_x, then this variable definition will keep it’s center at a relative position in the simulation box, 1/4 of the way from the left edge to the right edge, even if the box size changes:

```plaintext
variable x equal "xlo + 0.25*lx"
```

Similarly, either of these variable definitions will move the indenter from an initial position at 2.5 at a constant velocity of 5:

```plaintext
variable x equal "2.5 + 5*elaplong*dt"
variable x equal vdisplace(2.5,5)
```

If a spherical indenter’s radius is specified as v_r, then these variable definitions will grow the size of the indenter at a specified rate.

```plaintext
variable r0 equal 0.0
variable rate equal 1.0
variable r equal "v_r0 + step*dt*v_rate"
```

If the side keyword is specified as out, which is the default, then particles outside the indenter are pushed away from its outer surface, as described above. This only applies to spherical or cylindrical indenters. If the side keyword is specified as in, the action of the indenter is reversed. Particles inside the indenter are pushed away from its inner surface. In other words, the indenter is now a containing wall that traps the particles inside it. If the radius shrinks over time, it will squeeze the particles.

The units keyword determines the meaning of the distance units used to define the indenter geometry. A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacing. The (x,y,z) coords of the indenter position are scaled by the x,y,z lattice spacings respectively. The radius of a spherical or cylindrical indenter is scaled by the x lattice spacing.

Note that the units keyword only affects indenter geometry parameters specified directly with numbers, not those specified as variables. In the latter case, you should use the xlat, ylat, zlat keywords of the thermo_style command if you want to include lattice spacings in a variable formula.

The force constant $K$ is not affected by the units keyword. It is always in force/distance^2 units where force and distance are defined by the units command. If you wish K to be scaled by the lattice spacing, you can define K with a variable whose formula contains xlat, ylat, zlat keywords of the thermo_style command, e.g.

```plaintext
variable k equal 100.0/xlat/xlat
fix 1 all indent $k sphere ...
```
18.62.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the energy of interaction between atoms and the indenter to the system’s potential energy as part of thermodynamic output. The energy of each particle interacting with the indenter is \( \frac{K}{3} (r - R)^3 \).

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar energy and a global 3-vector of forces (on the indenter), which can be accessed by various output commands. The scalar and vector values calculated by this fix are “extensive”.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command. Note that if you define the indenter geometry with a variable using a time-dependent formula, LAMMPS uses the iteration count in the minimizer as the timestep. But it is almost certainly a bad idea to have the indenter change its position or size during a minimization. LAMMPS does not check if you have done this.

Note: If you want the atom/indenter interaction energy to be included in the total potential energy of the system (the quantity being minimized), you must enable the fix_modify energy option for this fix.

18.63 fix ipi command

18.63.1 Syntax

```plaintext
fix ID group-ID ipi address port [unix] [reset]
```

- ID, group-ID are documented in fix command
- ipi = style name of this fix command
- address = internet address (FQDN or IP), or UNIX socket name
- port = port number (ignored for UNIX sockets)
- optional keyword = unix, if present uses a unix socket
- optional keyword = reset, if present reset electrostatics at each call
18.63.2 Examples

```plaintext
fix 1 all ipi my.server.com 12345
fix 1 all ipi mysocket 666 unix reset
```

18.63.3 Description

This fix enables LAMMPS to be run as a client for the i-PI Python wrapper (IPI) for performing a path integral molecular dynamics (PIMD) simulation. The philosophy behind i-PI is described in the following publication (IPI-CPC).

A version of the i-PI package, containing only files needed for use with LAMMPS, is provided in the tools/i-pi directory. See the tools/i-pi/manual.pdf for an introduction to i-PI. The examples/USER/i-pi directory contains example scripts for using i-PI with LAMMPS.

In brief, the path integral molecular dynamics is performed by the Python wrapper, while the client (LAMMPS in this case) simply computes forces and energy for each configuration. The communication between the two components takes place using sockets, and is reduced to the bare minimum. All the parameters of the dynamics are specified in the input of i-PI, and all the parameters of the force field must be specified as LAMMPS inputs, preceding the fix ipi command.

The server address must be specified by the address argument, and can be either the IP address, the fully-qualified name of the server, or the name of a UNIX socket for local, faster communication. In the case of internet sockets, the port argument specifies the port number on which i-PI is listening, while the unix optional switch specifies that the socket is a UNIX socket.

Note that there is no check of data integrity, or that the atomic configurations make sense. It is assumed that the species in the i-PI input are listed in the same order as in the data file of LAMMPS. The initial configuration is ignored, as it will be substituted with the coordinates received from i-PI before forces are ever evaluated.

A note of caution when using potentials that contain long-range electrostatics, or that contain parameters that depend on box size: all of these options will be initialized based on the cell size in the LAMMPS-side initial configuration and kept constant during the run. This is required to e.g. obtain reproducible and conserved forces. If the cell varies too wildly, it may be advisable to re-initialize these interactions at each call. This behavior can be requested by setting the reset switch.

18.63.4 Restart, fix_modify, output, run start/stop, minimize info

There is no restart information associated with this fix, since all the dynamical parameters are dealt with by i-PI.

18.63.5 Restrictions

Using this fix on anything other than all atoms requires particular care, since i-PI will know nothing on atoms that are not those whose coordinates are transferred. However, one could use this strategy to define an external potential acting on the atoms that are moved by i-PI.

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info. Because of the use of UNIX domain sockets, this fix will only work in a UNIX environment.

```

18.64.3 Description

Apply a Langevin thermostat as described in (Schneider) to a group of atoms which models an interaction with a background implicit solvent. Used with fix nve, this command performs Brownian dynamics (BD), since the total force on each atom will have the form:

\[ F = F_c + F_f + F_r \]
\[ F_f = -\frac{m}{\text{damp}} v \]
\[ F_r \propto \sqrt{\frac{k_B T m}{dt \text{ damp}}} \]

\( F_c \) is the conservative force computed via the usual inter-particle interactions (pair_style, bond_style, etc). The \( F_f \) and \( F_r \) terms are added by this fix on a per-particle basis. See the pair_style dpd/tstat command for a thermostatting option that adds similar terms on a pairwise basis to pairs of interacting particles.

\( F_f \) is a frictional drag or viscous damping term proportional to the particle’s velocity. The proportionality constant for each atom is computed as \( \frac{m}{\text{damp}} \), where \( m \) is the mass of the particle and \( \text{damp} \) is the damping factor specified by the user.

\( F_r \) is a force due to solvent atoms at a temperature \( T \) randomly bumping into the particle. As derived from the fluctuation/dissipation theorem, its magnitude as shown above is proportional to \( \sqrt{\frac{k_B T m}{dt \text{ damp}}} \), where \( k_B \) is the Boltzmann constant, \( T \) is the desired temperature, \( m \) is the mass of the particle, \( dt \) is the timestep size, and \( \text{damp} \) is the damping factor. Random numbers are used to randomize the direction and magnitude of this force as described in (Dunweg), where a uniform random number is used (instead of a Gaussian random number) for speed.

Note that unless you use the omega or angmom keywords, the thermostat effect of this fix is applied to only the translational degrees of freedom for the particles, which is an important consideration for finite-size particles, which have rotational degrees of freedom, are being thermostatted. The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

Note: Unlike the fix nvt command which performs Nose/Hoover thermostatting AND time integration, this fix does NOT perform time integration. It only modifies forces to effect thermostatting. Thus you must use a separate time integration fix, like fix nve to actually update the velocities and positions of atoms using the modified forces. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by fix nvt or fix temp/rescale commands.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostatting.

The desired temperature at each timestep is a ramped value during the run from \( T_{start} \) to \( T_{stop} \).

\( T_{start} \) can be specified as an equal-style or atom-style variable. In this case, the \( T_{stop} \) setting is ignored. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.
the equation above and of

soid defines a finite size and shape for aspherical particles and an angular momentum. The Langevin formulas for

rotational degrees of freedom are the same as those above, where force is replaced by torque, m is

replaced by the moment of inertia I, and v is replaced by omega (which is derived from the angular momentum in the

case of aspherical particles).

The rotational temperature of the particles can be monitored by the

compute temp/sphere and compute temp/asphere

commands with their rotate options.

For the omega keyword there is also a scale factor of \( \frac{10.0}{3.0} \) that is applied as a multiplier on the \( F_f \) (damping) term in

the equation above and of \( \sqrt{\frac{10.0}{3.0}} \) as a multiplier on the \( F_r \) term. This does not affect the thermostatting behavior of

the Langevin formalism but insures that the randomized rotational diffusivity of spherical particles is correct.

For the angmom keyword a similar scale factor is needed which is \( \frac{10.0}{3.0} \) for spherical particles, but is anisotropic for

aspherical particles (e.g. ellipsoids). Currently LAMMPS only applies an isotropic scale factor, and you can choose

its magnitude as the specified value of the angmom keyword. If your aspherical particles are (nearly) spherical than a

value of \( \frac{10.0}{3.0} \) is a good choice. If they are highly aspherical, a value of 1.0 is as good a choice as any, since the

effects on rotational diffusivity of the particles will be incorrect regardless. Note that for any reasonable scale factor, the

thermostatting effect of the angmom keyword on the rotational temperature of the aspherical particles should still be

valid.

The keyword scale allows the damp factor to be scaled up or down by the specified factor for atoms of that type. This

can be useful when different atom types have different sizes or masses. It can be used multiple times to adjust damp for

several atom types. Note that specifying a ratio of 2 increases the relaxation time which is equivalent to the solvent’s

viscosity acting on particles with \( \frac{1}{2} \) the diameter. This is the opposite effect of scale factors used by the fix viscous

command, since the damp factor in fix langevin is inversely related to the \( \gamma \) factor in fix viscous. Also note that the

damping factor in fix langevin includes the particle mass in Ff, unlike fix viscous. Thus the mass and size of different

atom types should be accounted for in the choice of ratio values.

The keyword tally enables the calculation of the cumulative energy added/subtracted to the atoms as they are ther-

mostatted. Effectively it is the energy exchanged between the infinite thermal reservoir and the particles. As described
below, this energy can then be printed out or added to the potential energy of the system to monitor energy conservation.

Note: this accumulated energy does NOT include kinetic energy removed by the zero flag. LAMMPS will print a warning when both options are active.

The keyword zero can be used to eliminate drift due to the thermostat. Because the random forces on different atoms are independent, they do not sum exactly to zero. As a result, this fix applies a small random force to the entire system, and the center-of-mass of the system undergoes a slow random walk. If the keyword zero is set to yes, the total random force is set exactly to zero by subtracting off an equal part of it from each atom in the group. As a result, the center-of-mass of a system with zero initial momentum will not drift over time.

The keyword gif can be used to run the Gronbech-Jensen/Farago time-discretization of the Langevin model. As described in the papers cited below, the purpose of this method is to enable longer timesteps to be used (up to the numerical stability limit of the integrator), while still producing the correct Boltzmann distribution of atom positions.

The current implementation provides the user with the option to output the velocity in one of two forms: vfull or vhalf, which replaces the outdated option yes. The gif option vfull outputs the on-site velocity given in Gronbech-Jensen/Farago; this velocity is shown to be systematically lower than the target temperature by a small amount, which grows quadratically with the timestep. The gif option vhalf outputs the 2GJ half-step velocity given in Gronbech Jensen/Gronbech-Jensen; for linear systems, this velocity is shown to not have any statistical errors for any stable time step. An overview of statistically correct Boltzmann and Maxwell-Boltzmann sampling of true on-site and true half-step velocities is given in Gronbech-Jensen. Regardless of the choice of output velocity, the sampling of the configurational distribution of atom positions is the same, and linearly consistent with the target temperature.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

18.64.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

The fix_modify temp option is supported by this fix. You can use it to assign a temperature compute you have defined to this fix which will be used in its thermostatting procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The fix_modify energy option is supported by this fix to add the energy change induced by Langevin thermostatting to the system’s potential energy as part of thermodynamic output. Note that use of this option requires setting the tally keyword to yes.

18.64. fix langevin command
This fix computes a global scalar which can be accessed by various output commands. The scalar is the cumulative energy change due to this fix. The scalar value calculated by this fix is “extensive”. Note that calculation of this quantity requires setting the tally keyword to yes.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

### 18.64.5 Restrictions

For gif do not choose damp=dt/2. gif is not compatible with run_style respa.

### 18.64.6 Related commands

```

### 18.65.3 Description

Apply two Langevin thermostats as described in *(Jiang)* for thermalizing the reduced degrees of freedom of Drude oscillators. This link describes how to use the *thermalized Drude oscillator model* in LAMMPS and polarizable models in LAMMPS are discussed on the *Howto polarizable* doc page.

Drude oscillators are a way to simulate polarizables atoms, by splitting them into a core and a Drude particle bound by a harmonic bond. The thermalization works by transforming the particles degrees of freedom by these equations. In these equations upper case denotes atomic or center of mass values and lower case denotes Drude particle or dipole values. Primes denote the transformed (reduced) values, while bare letters denote the original values.

Velocities:

\[ V' = \frac{MV + mv}{M'} \]
\[ v' = v - V \]

Masses:

\[ M' = M + m \]
\[ m' = \frac{Mm}{M'} \]

The Langevin forces are computed as

\[ F' = -\frac{M'}{damp_{\text{com}}} V' + F'_{r} \]
\[ f' = -\frac{m'}{damp_{\text{drude}}} v' + f'_{r} \]

\( F'_{r} \) is a random force proportional to \( \sqrt{\frac{2k_BT_{com}m'}{dt\cdot\text{damp}_{\text{com}}}} \). \( f'_{r} \) is a random force proportional to \( \sqrt{\frac{2k_BT_{\text{drude}}m'}{dt\cdot\text{damp}_{\text{drude}}}} \). Then the real forces acting on the particles are computed from the inverse transform:

\[ F = \frac{M}{M'} F' - f' \]
\[ f = \frac{m}{M'} F' + f' \]

This fix also thermostats non-polarizable atoms in the group at temperature \( T_{\text{com}} \), as if they had a massless Drude partner. The Drude particles themselves need not be in the group. The center of mass and the dipole are thermostatted iff the core atom is in the group.
Note that the thermostat effect of this fix is applied to only the translational degrees of freedom of the particles, which is an important consideration if finite-size particles, which have rotational degrees of freedom, are being thermostatted. The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

**Note:** Like the `fix langevin` command, this fix does NOT perform time integration. It only modifies forces to effect thermostatting. Thus you must use a separate time integration fix, like `fix nve` or `fix nph` to actually update the velocities and positions of atoms using the modified forces. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by `fix nvt` or `fix temp/rescale` commands.

See the *Howto thermostat* doc page for a discussion of different ways to compute temperature and perform thermostatting.

This fix requires each atom know whether it is a Drude particle or not. You must therefore use the `fix drude` command to specify the Drude status of each atom type.

**Note:** only the Drude core atoms need to be in the group specified for this fix. A Drude electron will be transformed together with its cores even if it is not itself in the group. It is safe to include Drude electrons or non-polarizable atoms in the group. The non-polarizable atoms will simply be thermostatted as if they had a massless Drude partner (electron).

**Note:** Ghost atoms need to know their velocity for this fix to act correctly. You must use the `comm_modify` command to enable this, e.g.

```
comm_modify vel yes
```

*Tcom* is the target temperature of the centers of mass, which would be used to thermostat the non-polarizable atoms. *Tdrude* is the (normally low) target temperature of the core-Drude particle pairs (dipoles). *Tcom* and *Tdrude* can be specified as an equal-style variable. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature. Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

Like other fixes that perform thermostatting, this fix can be used with `compute commands` that remove a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms. This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in. **NOTE:** this feature has not been tested.

Note: The temperature thermostatting the core-Drude particle pairs should be chosen low enough, so as to mimic as closely as possible the self-consistent minimization. It must however be high enough, so that the dipoles can follow the local electric field exerted by the neighboring atoms. The optimal value probably depends on the temperature of the centers of mass and on the mass of the Drude particles.

*damp_com* is the characteristic time for reaching thermal equilibrium of the centers of mass. For example, a value of 100.0 means to relax the temperature of the centers of mass in a timespan of (roughly) 100 time units (tau or fs or ps...
- see the units command). 

\textit{damp\_drude} is the characteristic time for reaching thermal equilibrium of the dipoles. It is typically a few timesteps.

The number \textit{seed\_com} and \textit{seed\_drude} are positive integers. They set the seeds of the Marsaglia random number generators used for generating the random forces on centers of mass and on the dipoles. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The keyword \textit{zero} can be used to eliminate drift due to the thermostat on centers of mass. Because the random forces on different centers of mass are independent, they do not sum exactly to zero. As a result, this fix applies a small random force to the entire system, and the momentum of the total center of mass of the system undergoes a slow random walk. If the keyword \textit{zero} is set to \textit{yes}, the total random force on the centers of mass is set exactly to zero by subtracting off an equal part of it from each center of mass in the group. As a result, the total center of mass of a system with zero initial momentum will not drift over time.

The actual temperatures of cores and Drude particles, in center-of-mass and relative coordinates, respectively, can be calculated using the \textit{compute temp/drude} command.

\begin{verbatim}
Usage example for rigid bodies in the NPT ensemble:
comm_modify vel yes
fix TEMP all langevin/drude 300. 100. 1256 1. 20. 13977 zero yes
fix NPH ATOMS rigid/nph/small molecule iso 1. 1. 500.
fix NVE DRUDES nve
compute TDRUDE all temp/drude
\end{verbatim}

Comments:

\begin{itemize}
  \item Drude particles should not be in the rigid group, otherwise the Drude oscillators will be frozen and the system will lose its polarizability.
  \item \textit{zero yes} avoids a drift of the center of mass of the system, but is a bit slower.
  \item Use two different random seeds to avoid unphysical correlations.
  \item Temperature is controlled by the fix \textit{langevin/drude}, so the time-integration fixes do not thermostat. Don’t forget to time-integrate both cores and Drude particles.
  \item Pressure is time-integrated only once by using \textit{nve} for Drude particles and \textit{nph} for atoms/cores (or vice versa). Do not use \textit{nph} for both.
  \item The temperatures of cores and Drude particles are calculated by \textit{compute temp/drude}
  \item Contrary to the alternative thermostatting using Nose-Hoover thermostat fix \textit{npt} and \textit{fix drude/transform}, the \textit{fix modify} command is not required here, because the fix \textit{nph} computes the global pressure even if its group is \textit{ATOMS}. This is what we want. If we thermostatted \textit{ATOMS} using \textit{npt}, the pressure should be the global one, but the temperature should be only that of the cores. That’s why the command \textit{fix modify} should be called in that case.
\end{itemize}
18.65.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

The fix_modify temp option is supported by this fix. You can use it to assign a temperature compute you have defined to this fix which will be used in its thermostating procedure, as described above. For consistency, the group used by the compute should include the group of this fix and the Drude particles.

This fix is not invoked during energy minimization.

```

18.66.3 Description

Apply a Langevin thermostat as described in (Schneider) to a group of nuclei and electrons in the electron force field model. Used with fix nve/eff, this command performs Brownian dynamics (BD), since the total force on each atom will have the form:

\[ F = F_c + F_f + F_r \]

\[ F_f = -\frac{m}{\text{damp}} v \]

\[ F_r \propto \sqrt{\frac{k_B T m}{\text{damp}}} \]

\( F_c \) is the conservative force computed via the usual inter-particle interactions (pair_style). The \( F_f \) and \( F_r \) terms are added by this fix on a per-particle basis.

The operation of this fix is exactly like that described by the fix langevin command, except that the thermostatting is also applied to the radial electron velocity for electron particles.

18.66.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

The fix_modify temp option is supported by this fix. You can use it to assign a temperature compute you have defined to this fix which will be used in its thermostatting procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The fix_modify energy option is supported by this fix to add the energy change induced by Langevin thermostatting to the system’s potential energy as part of thermodynamic output. Note that use of this option requires setting the tally keyword to yes.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the cumulative energy change due to this fix. The scalar value calculated by this fix is “extensive”. Note that calculation of this quantity requires setting the tally keyword to yes.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.
18.66.5 Restrictions

none

This fix is part of the USER-EFF package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.66.6 Related commands

fix langevin

18.66.7 Default

The option defaults are scale = 1.0 for all types and tally = no.

(Schneider) Schneider and Stoll, Phys Rev B, 17, 1302 (1978).

18.67 fix langevin/spin command

18.67.1 Syntax

fix ID group-ID langevin/spin T Tdamp seed

- ID, group-ID are documented in fix command
- langevin/spin = style name of this fix command
- T = desired temperature of the bath (temperature units, K in metal units)
- Tdamp = transverse magnetic damping parameter (adim)
- seed = random number seed to use for white noise (positive integer)

18.67.2 Examples

fix 2 all langevin/spin 300.0 0.01 21

18.67.3 Description

Apply a Langevin thermostat as described in (Mayergoyz) to the magnetic spins associated to the atoms. Used with fix nve/spin, this command performs Brownian dynamics (BD). A random torque and a transverse dissipation are applied to each spin i according to the following stochastic differential equation:

\[
\frac{d\vec{s}_i}{dt} = \frac{1}{(1 + \lambda^2)} \left( (\vec{\omega}_i + \vec{\eta}) \times \vec{s}_i + \lambda \vec{s}_i \times (\vec{\omega}_i \times \vec{s}_i) \right)
\]

with \( \lambda \) the transverse damping, and \( \eta \) a random vector. This equation is referred to as the stochastic Landau-Lifshitz-Gilbert (sLLG) equation.
The components of $\eta$ are drawn from a Gaussian probability law. Their amplitude is defined as a proportion of the temperature of the external thermostat $T$ (in K in metal units).

More details about this implementation are reported in (Tranchida).

Note: due to the form of the sLLG equation, this fix has to be defined just before the nve/spin fix (and after all other magnetic fixes). As an example:

```
fix 1 all precession/spin zeeman 0.01 0.0 0.0 1.0
fix 2 all langevin/spin 300.0 0.01 21
fix 3 all nve/spin lattice moving
```

is correct, but defining a force/spin command after the langevin/spin command would give an error message.

Note: The random # seed must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

18.67.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

This fix is not invoked during energy minimization.

18.67.5 Restrictions

The langevin/spin fix is part of the SPIN package. This style is only enabled if LAMMPS was built with this package. See the Build package doc page for more info.

The numerical integration has to be performed with fix nve/spin when fix langevin/spin is enabled.

This fix has to be the last defined magnetic fix before the time integration fix (e.g. fix nve/spin).

18.67.6 Related commands

18.68 fix latte command

18.68.1 Syntax

```
fix ID group-ID latte peID
```

- ID, group-ID are documented in fix command
- latte = style name of this fix command
- peID = NULL or ID of compute used to calculate per-atom energy

18.68.2 Examples

```
fix dftb all latte NULL
```

18.68.3 Description

This fix style is a wrapper on the self-consistent charge transfer density functional based tight binding (DFTB) code LATTE. If you download and build LATTE, it can be called as a library by LAMMPS via this fix to run dynamics or perform energy minimization using DFTB forces and energies computed by LATTE.

LATTE is principally developed and supported by Marc Cawkwell and co-workers at Los Alamos National Laboratory (LANL). See the full list of contributors in the src/LATTE/README file.

To use this fix, the LATTE program needs to be compiled as a library and linked with LAMMPS. LATTE can be downloaded (or cloned) from https://github.com/lanl/LATTE. Instructions on how to download and build LATTE on your system can be found in the lib/latte/README file. Note that you can also use the “make lib-latte” command from the LAMMPS src directory to automate this process.

Once LAMMPS is built with the LATTE package, you can run the example input scripts for molecular dynamics or energy minimization that are found in examples/latte.

A step-by-step tutorial can be followed at: LAMMPS-LATTE tutorial

The peID argument is not yet supported by fix latte, so it must be specified as NULL. Eventually it will be used to enable LAMMPS to calculate a Coulomb potential as an alternative to LATTE performing the calculation.

LATTE is a code for performing self-consistent charge transfer tight-binding (SC-TB) calculations of total energies and the forces acting on atoms in molecules and solids. This tight-binding method is becoming more and more popular and widely used in chemistry, biochemistry, material science, etc.

The SC-TB formalism is derived from an expansion of the Kohn-Sham density functional to second order in charge fluctuations about a reference charge of overlapping atom-centered densities and bond integrals are parameterized using a Slater-Koster tight-binding approach. This procedure, which usually is referred to as the DFTB method has been described in detail by (Elstner) and (Finnis) and coworkers.

The work of the LATTE developers follows that of Elstner closely with respect to the physical model. However, the development of LATTE is geared principally toward large-scale, long duration, microcanonical quantum-based Born-Oppenheimer molecular dynamics (QMD) simulations. One of the main bottlenecks of an electronic structure calculation is the solution of the generalized eigenvalue problem which scales with the cube of the system size O(N^3).

The Theoretical and Computer sciences divisions at Los Alamos National Laboratory have accumulated large experience addressing this issue by calculating the density matrix directly instead of using diagonalization. We typically use
a recursive sparse Fermi-operator expansion using second-order spectral projection functions (SP2-algorithm), which was introduced by Niklasson in 2002 (Niklasson2002), (Rubensson), (Mniszewski). When the matrices involved in the recursive expansion are sufficiently sparse, the calculation of the density matrix scales linearly as a function of the system size O(N).

Another important feature is the extended Lagrangian framework for Born-Oppenheimer molecular dynamics (XL-BOMD) (Niklasson2008) (Niklasson2014), (Niklasson2017) that allows for a drastic reduction or even a complete removal of the iterative self-consistent field optimization. Often only a single density matrix calculation per molecular dynamics time step is required, yet total energy stability is well maintained. The SP2 and XL-BOMD techniques enables stable linear scaling MD simulations with a very small computational overhead. This opens a number of opportunities in many different areas of chemistry and materials science, as we now can simulate larger system sizes and longer time scales (Cawkwell2012), (Negre2016).

18.68.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the potential energy computed by LATTE to the system’s potential energy as part of thermodynamic output.

The fix_modify virial option is supported by this fix to add the LATTE DFTB contribution to the system’s virial as part of thermodynamic output. The default is virial yes

This fix computes a global scalar which can be accessed by various output commands. The scalar is the potential energy discussed above. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The DFTB forces computed by LATTE via this fix are imposed during an energy minimization, invoked by the minimize command.

Note: If you want the potential energy associated with the DFTB forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

18.68.5 Restrictions

This fix is part of the LATTE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

You must use metal units, as set by the units command to use this fix.

LATTE does not currently compute per-atom energy or per-atom virial contributions. So they will not show up as part of the calculations performed by the compute pe/atom or compute stress/atom commands.

Currently, LAMMPS must be run in serial or as a single MPI task, to use this fix. This is typically not a bottleneck, since LATTE will be doing 99% or more of the work to compute quantum-accurate forces.

Note: NEB calculations can be done using this fix using multiple replicas and running LAMMPS in parallel. However, each replica must be run on a single MPI task. For details, see the neb command doc page and the -partition command-line switch

18.69 fix lb/fluid command

18.69.1 Syntax

```
fix ID group-ID lb/fluid nevery LBtype viscosity density keyword values ...
```

- ID, group-ID are documented in `fix` command
- `lb/fluid` = style name of this fix command
- `nevery` = update the lattice-Boltzmann fluid every this many timesteps
- `LBtype` = 1 to use the standard finite difference LB integrator, 2 to use the LB integrator of Ollila et al.
- `viscosity` = the fluid viscosity (units of mass/(time*length)).
- `density` = the fluid density.
- zero or more keyword/value pairs may be appended
- `keyword` = `setArea` or `setGamma` or `scaleGamma` or `dx` or `dm` or `a0` or `noise` or `calcforce` or `trilinear` or `D3Q19` or `read_restart` or `write_restart` or `zwall_velocity` or `bodyforce` or `printfluid`
setArea values = type node_area
  type = atom type (1-N)
  node_area = portion of the surface area of the composite object associated with the particular atom type (used when the force coupling constant is set by default).

setGamma values = gamma
  gamma = user set value for the force coupling constant.

scaleGamma values = type gammaFactor
  type = atom type (1-N)
  gammaFactor = factor to scale the setGamma gamma value by, for the specified atom type.

dx values = dx_LB = the lattice spacing.

dm values = dm_LB = the lattice-Boltzmann mass unit.

a0 values = a_0_real = the square of the speed of sound in the fluid.

noise values = Temperature seed
  Temperature = fluid temperature.
  seed = random number generator seed (positive integer)

calcforce values = N forcegroup-ID
  N = output the force and torque every N timesteps
  forcegroup-ID = ID of the particle group to calculate the force and torque of

trilinear values = none (used to switch from the default Peskin interpolation stencil to the trilinear stencil).

D3Q19 values = none (used to switch from the default D3Q15, 15 velocity lattice, to the D3Q19, 19 velocity lattice).

read_restart values = restart file = name of the restart file to use to restart a fluid run.

write_restart values = N = write a restart file every N MD timesteps.

zwall_velocity values = velocity_bottom velocity_top = velocities along the y-direction of the bottom and top walls (located at z=zmin and z=zmax).

bodyforce values = bodyforcex bodyforcey bodyforcez = the x, y and z components of a constant body force added to the fluid.

printfluid values = N = print the fluid density and velocity at each grid point every N timesteps.

18.69.2 Examples

```

18.69.3 Description

Implement a lattice-Boltzmann fluid on a uniform mesh covering the LAMMPS simulation domain. The MD particles described by group-ID apply a velocity dependent force to the fluid.

The lattice-Boltzmann algorithm solves for the fluid motion governed by the Navier Stokes equations,

\[
\begin{align*}
\partial_t \rho + \partial_\beta (\rho u_\beta) &= 0 \\
\partial_t (\rho u_\alpha) + \partial_\beta (\rho u_\alpha u_\beta) &= \partial_\beta \sigma_{\alpha \beta} + F_\alpha + \partial_\beta (\eta_{\alpha \beta \gamma \nu} \partial_\gamma u_\nu)
\end{align*}
\]
with,

$$\eta_{\alpha\beta\gamma} = \eta \left[ \delta_{\alpha\gamma} \delta_{\beta\nu} + \delta_{\alpha\nu} \delta_{\beta\gamma} - \frac{2}{3} \delta_{\alpha\beta} \delta_{\nu\gamma} \right] + \Lambda \delta_{\alpha\beta} \delta_{\nu\gamma}$$

where $\rho$ is the fluid density, $u$ is the local fluid velocity, $\sigma$ is the stress tensor, $F$ is a local external force, and $\eta$ and $\Lambda$ are the shear and bulk viscosities respectively. Here, we have implemented

$$\sigma_{\alpha\beta} = -P_{\alpha\beta} = -\rho a_0 \delta_{\alpha\beta}$$

with $a_0$ set to $\frac{1}{3} \frac{dx}{dt}^2$ by default.

The algorithm involves tracking the time evolution of a set of partial distribution functions which evolve according to a velocity discretized version of the Boltzmann equation,

$$(\partial_t + e_i \partial_\alpha) f_i = -\frac{1}{\tau} (f_i - f_i^{eq}) + W_i$$

where the first term on the right hand side represents a single time relaxation towards the equilibrium distribution function, and $\tau$ is a parameter physically related to the viscosity. On a technical note, we have implemented a 15 velocity model (D3Q15) as default; however, the user can switch to a 19 velocity model (D3Q19) through the use of the D3Q19 keyword. This fix provides the user with the choice of two algorithms to solve this equation, through the specification of the keyword $\text{LBtype}$. If $\text{LBtype}$ is set equal to 1, the standard finite difference LB integrator is used. If $\text{LBtype}$ is set equal to 2, the algorithm of Ollila et al. is used.

Physical variables are then defined in terms of moments of the distribution functions,

$$\rho = \sum_i f_i$$

$$\rho u_\alpha = \sum_i f_i e_{i\alpha}$$

Full details of the lattice-Boltzmann algorithm used can be found in Mackay et al..

The fluid is coupled to the MD particles described by group-ID through a velocity dependent force. The contribution to the fluid force on a given lattice mesh site $j$ due to MD particle $\alpha$ is calculated as:

$$F_{ja} = \gamma (v_n - u_f) \zeta_{ja}$$

where $v_n$ is the velocity of the MD particle, $u_f$ is the fluid velocity interpolated to the particle location, and $\gamma$ is the force coupling constant. $\zeta$ is a weight assigned to the grid point, obtained by distributing the particle to the nearest lattice sites. For this, the user has the choice between a trilinear stencil, which provides a support of 8 lattice sites, or the immersed boundary method Peskin stencil, which provides a support of 64 lattice sites. While the Peskin stencil is seen to provide more stable results, the trilinear stencil may be better suited for simulation of objects close to walls, due to its smaller support. Therefore, by default, the Peskin stencil is used; however the user may switch to the trilinear stencil by specifying the keyword, $\text{trilinear}$.

By default, the force coupling constant, $\gamma$, is calculated according to

$$\gamma = \frac{2m_v m_u}{m_u + m_v} \left( \frac{1}{\Delta t_{\text{collision}}} \right)$$

Here, $m_v$ is the mass of the MD particle, $m_u$ is a representative fluid mass at the particle location, and $\Delta t_{\text{collision}}$ is a collision time, chosen such that $\frac{\tau}{\Delta t_{\text{collision}}} = 1$ (see Mackay and Denniston for full details). In order to calculate $m_u$, the fluid density is interpolated to the MD particle location, and multiplied by a volume, node_area * $dx_{LB}$, where node_area represents the portion of the surface area of the composite object associated with a given MD particle. By default, node_area is set equal to $dx_{LB}^2$; however specific values for given atom types can be set using the $\text{setArea}$ keyword.
The user also has the option of specifying their own value for the force coupling constant, for all the MD particles associated with the fix, through the use of the `setGamma` keyword. This may be useful when modelling porous particles. See Mackay et al. for a detailed description of the method by which the user can choose an appropriate $\gamma$ value.

**Note:** while this fix applies the force of the particles on the fluid, it does not apply the force of the fluid to the particles. When the force coupling constant is set using the default method, there is only one option to include this hydrodynamic force on the particles, and that is through the use of the `lb/viscous` fix. This fix adds the hydrodynamic force to the total force acting on the particles, after which any of the built-in LAMMPS integrators can be used to integrate the particle motion. However, if the user specifies their own value for the force coupling constant, as mentioned in Mackay et al., the built-in LAMMPS integrators may prove to be unstable. Therefore, we have included our own integrators `fix lb/rigid/pc/sphere`, and `fix lb/pc`, to solve for the particle motion in these cases. These integrators should not be used with the `lb/viscous` fix, as they add hydrodynamic forces to the particles directly. In addition, they can not be used if the force coupling constant has been set the default way.

**Note:** if the force coupling constant is set using the default method, and the `lb/viscous` fix is NOT used to add the hydrodynamic force to the total force acting on the particles, this physically corresponds to a situation in which an infinitely massive particle is moving through the fluid (since collisions between the particle and the fluid do not act to change the particle’s velocity). Therefore, the user should set the mass of the particle to be significantly larger than the mass of the fluid at the particle location, in order to approximate an infinitely massive particle (see the dragforce test run for an example).

Inside the fix, parameters are scaled by the lattice-Boltzmann timestep, $dt_{LB}$, grid spacing, $dx_{LB}$, and mass unit, $dm_{LB}$. $dt_{LB}$ is set equal to $\textit{nevery}$, $dt_{MD}$, where $dt_{MD}$ is the MD timestep. By default, $dm_{LB}$ is set equal to 1.0, and $dx_{LB}$ is chosen so that $\frac{\tau}{dt} = \frac{3\eta}{\rho dx^2}$ is approximately equal to 1. However, the user has the option of specifying their own values for $dm_{LB}$, and $dx_{LB}$, by using the optional keywords $dm$, and $dx$ respectively.

**Note:** Care must be taken when choosing both a value for $dx_{LB}$, and a simulation domain size. This fix uses the same subdivision of the simulation domain among processors as the main LAMMPS program. In order to uniformly cover the simulation domain with lattice sites, the lengths of the individual LAMMPS sub-domains must all be evenly divisible by $dx_{LB}$. If the simulation domain size is cubic, with equal lengths in all dimensions, and the default value for $dx_{LB}$ is used, this will automatically be satisfied.

Physical parameters describing the fluid are specified through viscosity, density, and $a0$. If the force coupling constant is set the default way, the surface area associated with the MD particles is specified using the `setArea` keyword. If the user chooses to specify a value for the force coupling constant, this is set using the `setGamma` keyword. These parameters should all be given in terms of the mass, distance, and time units chosen for the main LAMMPS run, as they are scaled by the LB timestep, lattice spacing, and mass unit, inside the fix.

The `setArea` keyword allows the user to associate a surface area with a given atom type. For example if a spherical composite object of radius R is represented as a spherical shell of N evenly distributed MD particles, all of the same type, the surface area per particle associated with that atom type should be set equal to $\frac{4\pi R^2}{N}$. This keyword should only be used if the force coupling constant, $\gamma$, is set the default way.

The `setGamma` keyword allows the user to specify their own value for the force coupling constant, $\gamma$, instead of using the default value.

The `scaleGamma` keyword should be used in conjunction with the `setGamma` keyword, when the user wishes to specify different $\gamma$ values for different atom types. This keyword allows the user to scale the `setGamma` $\gamma$ value by a factor, `gammaFactor`, for a given atom type.
The \( dx \) keyword allows the user to specify a value for the LB grid spacing.

The \( dm \) keyword allows the user to specify the LB mass unit.

If the \( a0 \) keyword is used, the value specified is used for the square of the speed of sound in the fluid. If this keyword is not present, the speed of sound squared is set equal to \( \frac{1}{3} \left( \frac{dx_{LB}}{dt_{LB}} \right)^2 \). Setting \( a0 > \left( \frac{dx_{LB}}{dt_{LB}} \right)^2 \) is not allowed, as this may lead to instabilities.

If the \textit{noise} keyword is used, followed by a positive temperature value, and a positive integer random number seed, a thermal lattice-Boltzmann algorithm is used. If \textit{LBtype} is set equal to 1 (i.e. the standard LB integrator is chosen), the thermal LB algorithm of \textit{Adhikari et al.} is used; however if \textit{LBtype} is set equal to 2 both the LB integrator, and thermal LB algorithm described in \textit{Ollila et al.} are used.

If the \textit{calcforce} keyword is used, both the fluid force and torque acting on the specified particle group are printed to the screen every \( N \) timesteps.

If the keyword \textit{trilinear} is used, the trilinear stencil is used to interpolate the particle nodes onto the fluid mesh. By default, the immersed boundary method, Peskin stencil is used. Both of these interpolation methods are described in \textit{Mackay et al.}.

If the keyword \textit{D3Q19} is used, the 19 velocity (D3Q19) lattice is used by the lattice-Boltzmann algorithm. By default, the 15 velocity (D3Q15) lattice is used.

If the keyword \textit{write_restart} is used, followed by a positive integer, \( N \), a binary restart file is printed every \( N \) LB timesteps. This restart file only contains information about the fluid. Therefore, a LAMMPS restart file should also be written in order to print out full details of the simulation.

\textbf{Note:} When a large number of lattice grid points are used, the restart files may become quite large.

In order to restart the fluid portion of the simulation, the keyword \textit{read_restart} is specified, followed by the name of the binary lb_fluid restart file to be used.

If the \textit{zwall_velocity} keyword is used \( y \)-velocities are assigned to the lower and upper walls. This keyword requires the presence of walls in the \( z \)-direction. This is set by assigning fixed boundary conditions in the \( z \)-direction. If fixed boundary conditions are present in the \( z \)-direction, and this keyword is not used, the walls are assumed to be stationary.

If the \textit{bodyforce} keyword is used, a constant body force is added to the fluid, defined by it’s \( x \), \( y \) and \( z \) components.

If the \textit{printfluid} keyword is used, followed by a positive integer, \( N \), the fluid densities and velocities at each lattice site are printed to the screen every \( N \) timesteps.

For further details, as well as descriptions and results of several test runs, see \textit{Mackay et al.}. Please include a citation to this paper if the lb_fluid fix is used in work contributing to published research.

\section*{18.69.4 Restart, fix_modify, output, run start/stop, minimize info}

Due to the large size of the fluid data, this fix writes it’s own binary restart files, if requested, independent of the main LAMMPS binary restart files; no information about lb_fluid is written to the main LAMMPS binary restart files.

None of the \textit{fix_modify} options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various \textit{output commands}. No parameter of this fix can be used with the \textit{start/stop} keywords of the \textit{run} command. This fix is not invoked during \textit{energy minimization}. 

1100 Chapter 18. Fixes
18.69.5 Restrictions

This fix is part of the USER-LB package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix can only be used with an orthogonal simulation domain.

Walls have only been implemented in the z-direction. Therefore, the boundary conditions, as specified via the main LAMMPS boundary command must be periodic for x and y, and either fixed or periodic for z. Shrink-wrapped boundary conditions are not permitted with this fix.

This fix must be used before any of fix lb/viscous, fix lb/momentum, fix lb/rigid/pc/sphere, and/ or fix lb/pc , as the fluid needs to be initialized before any of these routines try to access its properties. In addition, in order for the hydrodynamic forces to be added to the particles, this fix must be used in conjunction with the lb/viscous fix if the force coupling constant is set by default, or either the lb/viscous fix or one of the lb/rigid/pc/sphere or lb/pc integrators, if the user chooses to specify their own value for the force coupling constant.

18.69.6 Related commands

fix lb/viscous, fix lb/momentum, fix lb/rigid/pc/sphere, fix lb/pc

18.69.7 Default

By default, the force coupling constant is set according to

\[ \gamma = \frac{2m_u m_v}{m_u + m_v} \left( \frac{1}{\Delta t_{\text{collision}}} \right) \]

and an area of \(dx_{LB}^2\) per node, used to calculate the fluid mass at the particle node location, is assumed.

dx is chosen such that \(\tau = \frac{3\eta dt_{LB}}{\rho dx_{LB}^2}\) is approximately equal to 1. \(dm\) is set equal to 1.0. \(a0\) is set equal to \(\frac{1}{3} \left( \frac{dx_{LB}}{dt_{LB}} \right)^2\).

The Peskin stencil is used as the default interpolation method. The D3Q15 lattice is used for the lattice-Boltzmann algorithm. If walls are present, they are assumed to be stationary.

18.70 fix lb/momentum command

18.70.1 Syntax

|fix ID group-ID lb/momentum nevery keyword values ...|

- ID, group-ID are documented in the fix command
- lb/momentum = style name of this fix command
- nevery = adjust the momentum every this many timesteps
- zero or more keyword/value pairs may be appended
- keyword = linear

linear values = xflag yflag zflag
xflag, yflag, zflag = 0/1 to exclude/include each dimension.

18.70.2 Examples

|fix 1 sphere lb/momentum
fix 1 all lb/momentum linear 1 1 0|

18.70.3 Description

This fix is based on the fix momentum command, and was created to be used in place of that command, when a lattice-Boltzmann fluid is present.

Zero the total linear momentum of the system, including both the atoms specified by group-ID and the lattice-Boltzmann fluid every nevery timesteps. This is accomplished by adjusting the particle velocities and the fluid velocities at each lattice site.

Note: This fix only considers the linear momentum of the system.

By default, the subtraction is performed for each dimension. This can be changed by specifying the keyword linear, along with a set of three flags set to 0/1 in order to exclude/include the corresponding dimension.

18.70.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
18.70.5 Restrictions

Can only be used if a lattice-Boltzmann fluid has been created via the `fix lb/fluid` command, and must come after this command.

This fix is part of the USER-LB package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

    - innergroup-ID = ID of the atom group which does not experience a hydrodynamic force from the lattice-Boltzmann fluid
18.72.2 Examples

```plaintext
fix 1 spheres lb/rigid/pc/sphere
fix 1 all lb/rigid/pc/sphere force 1 0 0 innerNodes ForceAtoms
```

18.72.3 Description

This fix is based on the `fix rigid` command, and was created to be used in place of that fix, to integrate the equations of motion of spherical rigid bodies when a lattice-Boltzmann fluid is present with a user-specified value of the force-coupling constant. The fix uses the integration algorithm described in Mackay et al. to update the positions, velocities, and orientations of a set of spherical rigid bodies experiencing velocity dependent hydrodynamic forces. The spherical bodies are assumed to rotate as solid, uniform density spheres, with moments of inertia calculated using the combined sum of the masses of all the constituent particles (which are assumed to be point particles).

By default, all of the atoms that this fix acts on experience a hydrodynamic force due to the presence of the lattice-Boltzmann fluid. However, the `innerNodes` keyword allows the user to specify atoms belonging to a rigid object which do not interact with the lattice-Boltzmann fluid (i.e., these atoms do not feel a hydrodynamic force from the lattice-Boltzmann fluid). This can be used to distinguish between atoms on the surface of a non-porous object, and those on the inside.

This feature can be used, for example, when implementing a hard sphere interaction between two spherical objects. Instead of interactions occurring between the particles on the surfaces of the two spheres, it is desirable simply to place an atom at the center of each sphere, which does not contribute to the hydrodynamic force, and have these central atoms interact with one another.

Apart from the features described above, this fix is very similar to the rigid fix (although it includes fewer optional arguments, and assumes the constituent atoms are point particles); see `fix rigid` for a complete documentation.

18.72.4 Restart, fix_modify, output, run start/stop, minimize info

No information about the `rigid` and `rigid/nve` fixes are written to binary restart files.

Similar to the `fix rigid` command: The rigid fix computes a global scalar which can be accessed by various output commands. The scalar value calculated by these fixes is “intensive”. The scalar is the current temperature of the collection of rigid bodies. This is averaged over all rigid bodies and their translational and rotational degrees of freedom. The translational energy of a rigid body is $1/2 \, m \, v^2$, where $m$ = total mass of the body and $v$ = the velocity of its center of mass. The rotational energy of a rigid body is $1/2 \, I \, w^2$, where $I$ = the moment of inertia tensor of the body and $w$ = its angular velocity. Degrees of freedom constrained by the `force` and `torque` keywords are removed from this calculation.

All of these fixes compute a global array of values which can be accessed by various output commands. The number of rows in the array is equal to the number of rigid bodies. The number of columns is 15. Thus for each rigid body, 15 values are stored: the xyz coords of the center of mass (COM), the xyz components of the COM velocity, the xyz components of the force acting on the COM, the xyz components of the torque acting on the COM, and the xyz image flags of the COM, which have the same meaning as image flags for atom positions (see the “dump” command). The force and torque values in the array are not affected by the `force` and `torque` keywords in the fix rigid command; they reflect values before any changes are made by those keywords.

The ordering of the rigid bodies (by row in the array) is as follows. For the single keyword there is just one rigid body. For the molecule keyword, the bodies are ordered by ascending molecule ID. For the group keyword, the list of group IDs determines the ordering of bodies.
The array values calculated by these fixes are “intensive”, meaning they are independent of the number of atoms in the simulation.

No parameter of these fixes can be used with the start/stop keywords of the run command. These fixes are not invoked during energy minimization.

18.72.5 Restrictions

This fix is part of the USER-LB package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Can only be used if a lattice-Boltzmann fluid has been created via the fix lb/fluid command, and must come after this command. Should only be used if the force coupling constant used in fix lb/fluid has been set by the user; this integration fix cannot be used if the force coupling constant is set by default.

18.72.6 Related commands

fix lb/fluid, fix lb/pc

18.72.7 Default

The defaults are force * on on on, and torque * on on on.

18.73 fix lb/viscous command

18.73.1 Syntax

```plaintext
fix ID group-ID lb/viscous
```

- ID, group-ID are documented in fix command
- lb/viscous = style name of this fix command

18.73.2 Examples

```plaintext
fix 1 flow lb/viscous
```
18.73.3 Description

This fix is similar to the fix viscous command, and is to be used in place of that command when a lattice-Boltzmann fluid is present, and the user wishes to integrate the particle motion using one of the built in LAMMPS integrators.

This fix adds a force, \( F = - \gamma \cdot (\text{velocity} - \text{fluid velocity}) \), to each atom, where \( \gamma \) is the force coupling constant described in the fix lb/fluid command (which applies an equal and opposite force to the fluid).

**Note:** This fix should only be used in conjunction with one of the built in LAMMPS integrators; it should not be used with the fix lb/pc or fix lb/rigid/pc/sphere integrators, which already include the hydrodynamic forces. These latter fixes should only be used if the force coupling constant has been set by the user (instead of using the default value); if the default force coupling value is used, then this fix provides the only method for adding the hydrodynamic forces to the particles.

For further details, as well as descriptions and results of several test runs, see Mackay et al.. Please include a citation to this paper if this fix is used in work contributing to published research.

18.73.4 Restart, fix_modify, output, run start/stop, minimize info

As described in the fix viscous documentation:

“No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command. This fix should only be used with damped dynamics minimizers that allow for non-conservative forces. See the min_style command for details.”

18.73.5 Restrictions

This fix is part of the USER-LB package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Can only be used if a lattice-Boltzmann fluid has been created via the fix lb/fluid command, and must come after this command.

This fix should not be used if either the fix lb/pc or fix lb/rigid/pc/sphere integrator is used.

18.73.6 Related commands

18.74 fix lineforce command

18.74.1 Syntax

```
fix ID group-ID lineforce x y z
```

- ID, group-ID are documented in fix command
- lineforce = style name of this fix command
- x y z = direction of line as a 3-vector

18.74.2 Examples

```
fix hold boundary lineforce 0.0 1.0 1.0
```

18.74.3 Description

Adjust the forces on each atom in the group so that only the component of force along the linear direction specified by the vector (x,y,z) remains. This is done by subtracting out components of force in the plane perpendicular to the line. If the initial velocity of the atom is 0.0 (or along the line), then it should continue to move along the line thereafter.

18.74.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

18.74.5 Restrictions

none
18.74.6 Related commands

fix planeforce

18.74.7 Default

none

18.75 fix manifoldforce command

18.75.1 Syntax

fix ID group-ID manifoldforce manifold manifold-args ...

- ID, group-ID are documented in fix command
- manifold = name of the manifold
- manifold-args = parameters for the manifold

18.75.2 Examples

fix constrain all manifoldforce sphere 5.0

18.75.3 Description

This fix subtracts each time step from the force the component along the normal of the specified manifold. This can be used in combination with minimize to remove overlap between particles while keeping them (roughly) constrained to the given manifold, e.g. to set up a run with fix nve/manifold/rattle. I have found that only hftn and quickmin with a very small time step perform adequately though.

18.75.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is invoked during energy minimization.
18.75.5 Restrictions

This fix is part of the USER-MANIFOLD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Only use this with min_style hftn or min_style quickmin. If not, the constraints will not be satisfied very well at all. A warning is generated if the min_style is incompatible but no error.

#### 18.76.3 Description

Perform updates of position, velocity, internal energy and local density for mesoscopic particles in the group each timestep using the specified settings or formulas, without regard to forces on the particles. This can be useful for boundary, solid bodies or other particles, whose movement can influence nearby particles.

The operation of this fix is exactly like that described by the `fix move` command, except that particles’ density, internal energy and extrapolated velocity are also updated.

**Note:** The particles affected by this fix should not be time integrated by other fixes (e.g. `fix sph`, `fix sph/stationary`), since that will change their positions and velocities twice.

**Note:** As particles move due to this fix, they will pass through periodic boundaries and be remapped to the other side of the simulation box, just as they would during normal time integration (e.g. via the `fix sph` command). It is up to you to decide whether periodic boundaries are appropriate with the kind of particle motion you are prescribing with this fix.

**Note:** As discussed below, particles are moved relative to their initial position at the time the fix is specified. These initial coordinates are stored by the fix in “unwrapped” form, by using the image flags associated with each particle. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each particle. You can reset the image flags (e.g. to 0) before invoking this fix by using the `set image` command.

The `linear` style moves particles at a constant velocity, so that their position \( X = (x,y,z) \) as a function of time is given in vector notation as

\[
X(t) = X_0 + V \times \delta
\]

where \( X_0 = (x_0,y_0,z_0) \) is their position at the time the fix is specified, \( V \) is the specified velocity vector with components \( (V_x,V_y,V_z) \), and \( \delta \) is the time elapsed since the fix was specified. This style also sets the velocity of each particle to \( V = (V_x,V_y,V_z) \). If any of the velocity components is specified as NULL, then the position and velocity of that component is time integrated the same as the `fix sph` command would perform, using the corresponding force component on the particle.

Note that the `linear` style is identical to using the `variable` style with an `equal-style variable` that uses the `vdisplace()` function. E.g.

```plaintext
variable V equal 10.0
variable x equal vdisplace(0.0,SV)
fix 1 boundary move variable v_x NULL NULL v_V NULL NULL
```

The `wiggle` style moves particles in an oscillatory fashion, so that their position \( X = (x,y,z) \) as a function of time is given in vector notation as
\[ X(t) = X_0 + A \sin(\omega \cdot \delta) \]

where \(X_0 = (x_0,y_0,z_0)\) is their position at the time the fix is specified, \(A\) is the specified amplitude vector with components \((A_x,A_y,A_z)\), \(\omega\) is \(2\pi/\text{period}\), and \(\delta\) is the time elapsed since the fix was specified. This style also sets the velocity of each particle to the time derivative of this expression. If any of the amplitude components is specified as NULL, then the position and velocity of that component is time integrated the same as the \textit{fix sph} command would perform, using the corresponding force component on the particle.

Note that the \textit{wiggle} style is identical to using the \textit{variable} style with \textit{equal-style variables} that use the \texttt{wiggle()} and \texttt{cwiggle()} functions. E.g.

```plaintext
variable A equal 10.0
variable T equal 5.0
variable omega equal 2.0*PI/$T
variable x equal swiggle(0.0,$A,$T)
variable v equal v_omega*(SA-cwiggle(0.0,$A,$T))
fix 1 boundary move variable v_x NULL NULL v_v NULL NULL
```

The \textit{rotate} style rotates particles around a rotation axis \(R = (R_x,R_y,R_z)\) that goes through a point \(P = (P_x,P_y,P_z)\). The \textit{period} of the rotation is also specified. The direction of rotation for the particles around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along \(R\), then your fingers wrap around the axis in the direction of rotation.

This style also sets the velocity of each particle to \((\omega \times R_{perp})\) where \(\omega\) is its angular velocity around the rotation axis and \(R_{perp}\) is a perpendicular vector from the rotation axis to the particle.

The \textit{variable} style allows the position and velocity components of each particle to be set by formulas specified via the \textit{variable} command. Each of the 6 variables is specified as an argument to the fix as \texttt{v\_name}, where \texttt{name} is the variable name that is defined elsewhere in the input script.

Each variable must be of either the \textit{equal} or \textit{atom} style. \textit{Equal-style} variables compute a single numeric quantity, that can be a function of the timestep as well as of other simulation values. \textit{Atom-style} variables compute a numeric quantity for each particle, that can be a function per-atom quantities, such as the particle’s position, as well as of the timestep and other simulation values. Note that this fix stores the original coordinates of each particle (see note below) so that per-atom quantity can be used in an atom-style variable formula. See the \textit{variable} command for details.

The first 3 variables \((v\_dx,v\_dy,v\_dz)\) specified for the \textit{variable} style are used to calculate a displacement from the particle’s original position at the time the fix was specified. The second 3 variables \((v\_vx,v\_vy,v\_vz)\) specified are used to compute a velocity for each particle.

Any of the 6 variables can be specified as NULL. If both the displacement and velocity variables for a particular \(x,y,z\) component are specified as NULL, then the position and velocity of that component is time integrated the same as the \textit{fix sph} command would perform, using the corresponding force component on the particle. If only the velocity variable for a component is specified as NULL, then the displacement variable will be used to set the position of the particle, and its velocity component will not be changed. If only the displacement variable for a component is specified as NULL, then the velocity variable will be used to set the velocity of the particle, and the position of the particle will be time integrated using that velocity.

The \textit{units} keyword determines the meaning of the distance units used to define the \textit{linear} velocity and \textit{wiggle} amplitude and \textit{rotate} origin. This setting is ignored for the \textit{variable} style. A \textit{box} value selects standard units as defined by the \textit{units} command, e.g. velocity in Angstroms/fs and amplitude and position in Angstroms for units = real. A \textit{lattice} value means the velocity units are in lattice spacings per time and the amplitude and position are in lattice spacings. The \textit{lattice} command must have been previously used to define the lattice spacing. Each of these 3 quantities may be dependent on the \(x,y,z\) dimension, since the lattice spacings can be different in \(x,y,z\).
18.76.4  Restart, fix_modify, output, run start/stop, minimize info

This fix writes the original coordinates of moving particles to binary restart files, as well as the initial timestep, so that the motion can be continuous in a restarted simulation. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

Note: Because the move positions are a function of the current timestep and the initial timestep, you cannot reset the timestep to a different value after reading a restart file, if you expect a fix move command to work in an uninterrupted fashion.

None of the fix_modify options are relevant to this fix.

This fix produces a per-atom array which can be accessed by various output commands. The number of columns for each atom is 3, and the columns store the original unwrapped x,y,z coords of each particle. The per-atom values can be accessed on any timestep.

No parameter of this fix can be used with the start/stop keywords of the run command.

This fix is not invoked during energy minimization.

18.76.5 Restrictions

This fix is part of the USER-SDPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix requires that atoms store density and internal energy as defined by the atom_style sph command.

All particles in the group must be mesoscopic SPH/SDPD particles.

18.76.6 Related commands

fix move, fix sph, displace_atoms

18.76.7 Default

The option default is units = lattice.

18.77  fix_modify AtC commands

18.77.1 fix_modify AtC add_molecule command

Syntax

fix_modify <AtC fixID> add_molecule <small|large> <tag> <group-ID>

- AtC fixID = ID of fix atc instance
- add_molecule = name of the AtC sub-command
- small or large = can be small if molecule size < cutoff radius, must be large otherwise
- tag = tag for tracking a molecule
• \textit{group-ID} = LAMMPS defined group-ID

Examples

\begin{verbatim}
group WATERGROUP type 1 2
fix_modify AtC add_molecule small water WATERGROUP
\end{verbatim}

Description

Associates a tag with all molecules corresponding to a specified group.

Restrictions

None.

Related AtC commands

• \textit{fix_modify AtC command overview}
• \textit{fix_modify AtC add_species}
• \textit{fix_modify AtC remove_species}
• \textit{fix_modify AtC remove_molecule}

Default

None.

18.77.2 \textit{fix_modify AtC add_species} command

Syntax

\begin{verbatim}
fix_modify <AtC fixID> add_species <tag> <group|type> <ID>
\end{verbatim}

• AtC fixID = ID of \textit{fix atc} instance
• add_species = name of the AtC sub-command
• tag = tag for tracking a species
• \textit{group} or \textit{type} = LAMMPS defined group or type of atoms
• ID = name of group or type number
Examples

```
fix_modify AtC add_species gold type l
group GOLDGROUP type l
fix_modify AtC add_species gold group GOLDGROUP
```

Description

Associates a tag with all atoms of a specified type or within a specified group.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC add_molecule`
- `fix_modify AtC remove_species`
- `fix_modify AtC remove_molecule`

Default

None.

18.77.3 fix_modify AtC atom_element_map command

Syntax

```
fix_modify <AtC fixID> atom_element_map <eulerian|lagrangian> [<frequency>]
```

- AtC fixID = ID of `fix atc` instance
- atom_element_map = name of the AtC sub-command
- `eulerian` or `lagrangian` = frame of reference
- frequency = frequency of updating atom-to-continuum maps based on the current configuration - (only for eulerian)
Examples

```
fix_modify AtC atom_element_map eulerian 100
```

Description

Changes frame of reference from *eulerian* to *lagrangian* or vice versa and sets the frequency for which the map from atoms to elements is reformed and all the attendant data is recalculated.

Restrictions

Cannot change map type after initialization.

Related AtC commands

- `fix_modify AtC command overview`

Default

*lagrangian*

### 18.77.4 fix_modify AtC atom_weight command

Syntax

```
fix_modify <AtC fixID> atom_weight <method> <args>
```

- **AtC fixID** = ID of *fix atc* instance
- **atom_weight** = name of the AtC sub-command
- **method** = constant or lattice or element or region or group or read_in
  - **constant** <group-ID> <value>: atoms in specified group are assigned the constant value given
  - **lattice**: volume per atom for specified lattice type (e.g. fcc) and parameter
  - **element**: element volume divided among atoms within element
  - **region**: volume per atom determined based on the atom count in the MD regions and their volumes. Note: meaningful only if atoms completely fill all the regions.
  - **group**: volume per atom determined based on the atom count in a group and its volume
  - **node**: (undocumented)
  - **node_element**: (undocumented)
  - **read_in<filename>**: list of values for atoms are read-in from specified file
Examples

```plaintext
fix_modify AtC atom_weight constant myatoms 11.8
fix_modify AtC atom_weight lattice
fix_modify AtC atom_weight read-in atm_wt_file.txt
```

Description

Command for assigning the value of atomic weights used for atomic integration in atom-continuum coupled simulations.

Restrictions

The use of the lattice option requires a lattice type and parameter is already specified.

Related AtC commands

- fix_modify AtC command overview

Default

lattice

18.77.5 fix_modify AtC atomic_charge command

Syntax

```plaintext
fix_modify <AtC fixID> <include|omit> atomic_charge
```

- AtC fixID = ID of fix atc instance
- include or omit = switch to activate/deactivate inclusion of intrinsic atomic charge in ATC
- atomic_charge = name of the AtC sub-command

Examples

```plaintext
fix_modify AtC include atomic_charge
```
Description

Determines whether AtC tracks the total charge as a finite element field.

Restrictions

Required for: *electrostatics*

Related AtC commands

- *fix_modify AtC command overview*

Default

If the atom charge is defined, default is on, otherwise default is off.

18.77.6 **fix_modify AtC boundary_dynamics command**

Syntax

```
fix_modify <AtC fixID> boundary_dynamics <on|damped_harmonic|prescribed|coupled|none>
```

- AtC fixID = ID of *fix atc* instance
- boundary_dynamics = name of the AtC sub-command
- *on* or *damped_harmonic* prescribed coupled none

Description

Sets different schemes for controlling boundary atoms. *on* will integrate the boundary atoms using the velocity-verlet algorithm. *damped_harmonic* uses a mass/spring/dashpot for the boundary atoms with added arguments of the damping and spring constants followed by the ratio of the boundary type mass to the desired mass. *prescribed* forces the boundary atoms to follow the finite element displacement. *coupled* does the same.

Restrictions

Boundary atoms must be specified. When using swaps between internal and boundary atoms, the initial configuration must have already correctly partitioned the two.
Related AtC commands

• *fix_modify AtC command overview*

Default

*prescribed on*

**18.77.7 fix_modify AtC boundary_faceset command**

**Syntax**

```
fix_modify <AtC fixID> boundary_faceset <is|add> <faceset_name>
```

• AtC fixID = ID of fix atc instance
• boundary_faceset = name of the AtC sub-command
• is or add = select whether to select or add a faceset
• faceset_name = name of the faceset

**Examples**

```
fix_modify AtC boundary_faceset is obndy
```

**Description**

This command specifies the faceset name when using a faceset to compute the MD/FE boundary fluxes. The faceset must already exist.

**Restrictions**

This is only valid when *fe_md_boundary* is set to *faceset*.

**Related AtC commands**

• *fix_modify AtC command overview*
• *fix_modify AtC fe_md_boundary*
• *fix_modify AtC mesh create_faceset box*
• *fix_modify AtC mesh create_faceset plane*
18.77.8 fix_modify AtC boundary type command

Syntax

```
fix_modify <AtC fixID> boundary type <atom-type-id>
```

- AtC fixID = ID of fix atc instance
- boundary type = name of the AtC sub-command
- atom-type-id = type id for atoms that represent a fictitious boundary internal to the FE mesh

Examples

```
fix_modify AtC boundary type ghost_atoms
```

Description

Command to define the atoms that represent the fictitious boundary internal to the FE mesh. For fully overlapped MD/FE domains with periodic boundary conditions no boundary atoms should be defined.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`

Default

None.

18.77.9 fix_modify AtC consistent_fe_initialization command

Syntax

```
fix_modify <AtC fixID> consistent_fe_initialization <on|off>
```

- AtC fixID = ID of fix atc instance
- consistent_fe_initialization = name of the AtC sub-command
- on or off = switch to activate/deactivate the initial setting of the FE intrinsic field to match the projected MD field
Examples

```plaintext
fix_modify AtC consistent_fe_initialization on
```

Description

Determines whether AtC initializes FE intrinsic fields (e.g., temperature) to match the projected MD values. This is particularly useful for fully overlapping simulations.

Restrictions

Can be used with: `thermal, two_temperature`. Cannot be used with time filtering on. Does not include boundary nodes.

Related AtC commands

- `fix_modify AtC command overview`

Default

Default is `off`

18.77.10 `fix_modify` AtC control localized_lambda command

Syntax

```plaintext
fix_modify <AtC fixID> control localized_lambda <on|off>
```

- AtC fixID = ID of `fix atc` instance
- control localized_lambda = name of the AtC sub-command
- `on` or `off` = Toggles state of localization algorithm

Examples

```plaintext
fix_modify AtC control localized_lambda on
```

Description

Turns the localization algorithms `on` or `off` for control algorithms to restrict the influence of FE coupling or boundary conditions to a region near the boundary of the MD region. Control algorithms will not affect atoms in elements not possessing faces on the boundary of the region. Flux-based control is localized via row-sum lumping while quantity control is done by solving a truncated matrix equation.
Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`

Default

off

18.77.11 fix_modify AtC control momentum command

Syntax

```plaintext
fix_modify <AtC fixID> control <physics_type> <solution_parameter> <value>
fix_modify AtC control momentum none
fix_modify AtC control momentum rescale <frequency>
fix_modify AtC control momentum glc_displacement
fix_modify AtC control momentum glc_velocity
fix_modify AtC control momentum hoover
fix_modify AtC control momentum flux [faceset face_set_id, interpolate]
```

- `AtC fixID = ID of fix atc instance`
- `control = name of the AtC sub-command`
- `physics_type = thermal or momentum`
- `solution_parameter = max_iterations or tolerance`
- `value = solution_parameter value`
- `momentum option = none or rescale or glc_displacement or glc_velocity hoover or flux`
- `frequency = time step frequency for applying displacement and velocity rescaling`
- `faceset_id = id of boundary face set (optional, only for faceset)`

Examples

```plaintext
fix_modify AtC control momentum none
fix_modify AtC control momentum flux faceset bndy_faces
fix_modify AtC control momentum glc_velocity
```
**Description**

The general version of control sets the numerical parameters for the matrix solvers used in the specified control algorithm. Many solution approaches require iterative solvers, and these methods enable users to provide the maximum number of iterations and the relative tolerance.

The control momentum version sets the momentum exchange mechanism from the finite elements to the atoms, managed through a control algorithm. rescale computes a scale factor for each atom to match the finite element temperature. hoover is a Gaussian least-constraint isokinetic thermostat enforces that the nodal restricted atomic temperature matches the finite element temperature. flux is a similar mode, but rather adds energy to the atoms based on conservation of energy.

correction_max_iterations sets the maximum number of iterations to compute the second order in time correction term for lambda with the fractional step method. The method uses the same tolerance as the controller’s matrix solver.

**Restrictions**

Only for be used with the specific controllers thermal or momentum. They are ignored if a lumped solution is requested. control momentum is only for be used with specific transfers: elastic rescale not valid with time filtering activated

**Related AtC commands**

- **fix_modify AtC command overview**
- **fix_modify AtC control thermal**

**Default**

- max_iterations is the number of rows in the matrix.
- tolerance is 1.0e-10.

**18.77.12 fix_modify AtC control thermal command**

**Syntax**

```
fix_modify <AtC fixID> control <physics_type> <solution_parameter> <value>
fix_modify <AtC fixID> control thermal <control_type> <optional_args>
fix_modify <AtC fixID> control thermal rescale <frequency>
fix_modify <AtC fixID> control thermal flux <boundary_integration_type> <faceset_id>
fix_modify <AtC fixID> control thermal correction_max_iterations <max_iterations>
```

- AtC fixID = ID of fix atc instance
- control = name of the AtC sub-command
- physics_type = thermal or momentum
- solution_parameter = max_iterations or tolerance
- value = solution_parameter value
- thermal control_type = none or rescale or hoover or flux
- frequency = time step frequency for applying velocity rescaling

18.77. fix_modify AtC commands
LAMMPS Documentation

- boundary_integration_type = faceset or interpolate (optional)
- faceset_id = id of boundary face set (optional, only for faceset)
- correction_max_iterations = maximum number of iterations that will be used by iterative matrix solvers for thermal physics type

Examples

```plaintext
fix_modify AtC control thermal none
fix_modify AtC control thermal rescale 10
fix_modify AtC control thermal hoover
fix_modify AtC control thermal flux
fix_modify AtC control thermal flux faceset bndy_faces
fix_modify AtC control thermal correction_max_iterations 10
```

Description

The general version of control sets the numerical parameters for the matrix solvers used in the specified control algorithm. Many solution approaches require iterative solvers, and these methods enable users to provide the maximum number of iterations and the relative tolerance.

The control thermal version sets the energy exchange mechanism from the finite elements to the atoms, managed through a control algorithm. rescale computes a scale factor for each atom to match the finite element temperature. hoover is a Gaussian least-constraint isokinetic thermostat enforces that the nodal restricted atomic temperature matches the finite element temperature. flux is a similar mode, but rather adds energy to the atoms based on conservation of energy. hoover and flux allow the prescription of sources or fixed temperatures on the atoms.

correction_max_iterations sets the maximum number of iterations to compute the second order in time correction term for lambda with the fractional step method. The method uses the same tolerance as the controller’s matrix solver.

Restrictions

Only for be used with the specific controllers thermal or momentum. They are ignored if a lumped solution is requested. control thermal is only for be used with specific transfers: thermal (rescale, hoover, flux), two_temperature (flux). rescale not valid with time filtering activated

correction_max_iterations is only for use with thermal physics using the fractional step method.

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC control momentum
Default

- `max_iterations` is the number of rows in the matrix.
- `tolerance` is 1.0e-10.
- `rescale` frequency is 1
- `flux boundary_integration_type` is `interpolate`
- `correction_max_iterations` is 20

18.77.13 fix_modify AtC decomposition command

Syntax

```
fix_modify <AtC fixID> decomposition <type>
```

- `AtC fixID` = ID of `fix atc` instance
- `decomposition` = name of the AtC sub-command
- `type` = `replicated_memory` or `distributed_memory`

Examples

```
fix_modify AtC decomposition distributed_memory
```

Description

Command for assigning the distribution of work and memory for parallel runs. With `replicated_memory` the nodal information is replicated on each processor, and with `distributed_memory` only the owned nodal information kept on each processor. The `replicated_memory` option is most appropriate for simulations were the number of nodes is much smaller than the number of atoms.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
18.77.14 fix_modify AtC extrinsic electron_integration command

Syntax

```
fix_modify <AtC fixID> extrinsic electron_integration <integration_type> [num_subcycle_steps]
```

- AtC fixID = ID of fix atc instance
- extrinsic electron_integration = name of the AtC sub-command
- integration_type = explicit or implicit or steady
- num_subcycle_steps = number of subcycle steps for the electron time integration (optional)

Examples

```
fix_modify AtC extrinsic electron_integration implicit
fix_modify AtC extrinsic electron_integration explicit 100
```

Description

Switches between integration schemes for the electron temperature. The number of subcycling steps used to integrate the electron temperature for one LAMMPS timestep can be manually adjusted to capture fast electron dynamics.

Restrictions

For use only with the two_temperature type of the AtC fix (see fix atc command)

Related AtC commands

- fix_modify AtC command overview

Default

implicit and subcycle_steps = 1
18.77.15  fix_modify AtC equilibrium_start command

Syntax

```bash
fix_modify <AtC fixID> equilibrium_start <on|off>
```

- `AtC fixID` = ID of `fix atc` instance
- `equilibrium_start` = name of the AtC sub-command
- `exponential` or `step` or `no_filter` = select type of filter

Examples

```bash
fix_modify AtC equilibrium_start on
```

Description

Starts filtered calculations assuming they start in equilibrium, i.e. perfect finite element force balance.

Restrictions

Only for use with these specific transfers: thermal, two_temperature

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC filter`
- `fix_modify AtC filter scale`

Default

None.

18.77.16  fix_modify AtC extrinsic exchange command

Syntax

```bash
fix_modify <AtC fixID> extrinsic exchange <on|off>
```

- `AtC fixID` = ID of `fix atc` instance
- `extrinsic exchange` = name of the AtC sub-command
- `on` or `off` = set state of energy exchange
Examples

```
fix_modify AtC extrinsic exchange on
```

Description

Switches energy exchange between the MD system and the electron system on or off

Restrictions

For use only with the two_temperature type of the AtC fix (see fix atc command)

Related AtC commands

- `fix_modify AtC command overview`

Default

`on`

18.77.17 fix_modify AtC fe_md_boundary command

Syntax

```
fix_modify <AtC fixID> fe_md_boundary <faceset|interpolate|no_boundary>
```

- AtC fixID = ID of fix atc instance
- fe_md_boundary = name of the AtC sub-command
- faceset or interpolate or no_boundary

Examples

```
fix_modify AtC fe_md_boundary interpolate
```

Description

Specifies different methods for computing fluxes between between the MD and FE integration regions. Faceset defines a faceset separating the MD and FE regions and uses finite element face quadrature to compute the flux. Interpolate uses a reconstruction scheme to approximate the flux, which is more robust but less accurate if the MD/FE boundary does correspond to a faceset. No boundary results in no fluxes between the systems being computed.
Restrictions

If *faceset* is used, all the AtC non-boundary atoms must lie within and completely fill the domain enclosed by the faceset.

Related AtC commands

- *fix_modify AtC command overview*
- *fix_modify AtC mesh create_faceset box*
- *fix_modify AtC mesh create_faceset plane*

Default

*interpolate*

18.77.18  *fix_modify AtC filter scale command*

Syntax

```
fix_modify <AtC fixID> filter scale <scale>
```

- AtC fixID = ID of *fix atc* instance
- filter scale = name of the AtC sub-command
- scale = characteristic times scale of the filter

Examples

```
fix_modify AtC filter scale 10.0
```

Description

Sets the time scale for MD dynamics filter to construct a more appropriate continuous field.

Restrictions

Only for use with these specific transfers: thermal, two_temperature
Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC filter
- fix_modify AtC filter type

Default

0.0

18.77.19 fix_modify AtC filter type command

Syntax

```
fix_modify <AtC fixID> filter type <exponential|step|no_filter>
```

- AtC fixID = ID of fix atc instance
- filter type = name of the AtC sub-command
- exponential or step or no_filter = select type of filter

Examples

```
fix_modify AtC filter type exponential
```

Description

Specifies the type of time filter used.

Restrictions

Only for use with these specific transfers: thermal, two_temperature

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC filter
- fix_modify AtC filter scale
Default

None.

18.77.20 fix_modify AtC fix command

Syntax

```
fix_modify <AtC fixID> fix <field> <nodeset> <constant|function>
```

- AtC fixID = ID of fix atc instance
- fix = name of the AtC sub-command
- field = field kind name valid for type of physics: temperature or electron_temperature
- nodeset = name of set of nodes to apply boundary condition
- constant or function = value or name of function followed by its parameters

Examples

```
fix_modify AtC fix temperature groupName 10.
fix_modify AtC fix temperature groupName 0 0 10.0 0 0 1.0
```

Description

Creates a constraint on the values of the specified field at specified nodes.

Restrictions

The keyword all is reserved and thus not available as nodeset name.

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC unfix

Default

None.
18.77.21  fix_modify AtC fix_flux command

Syntax

fix_modify <AtC fixID> fix_flux <field> <face_set> <value|function>

- AtC fixID = ID of fix atc instance
- fix_flux = name of the AtC sub-command
- field = field kind name valid for type of physics: temperature or electron_temperature
- face_set = name of set of element faces
- value or function = value or name of function followed by its parameters

Examples

fix_modify AtC fix_flux temperature faceSet 10.0

Description

Command for fixing normal fluxes e.g. heat_flux. This command only prescribes the normal component of the physical flux, e.g. heat (energy) flux. The units are in AtC units, i.e. derived from the LAMMPS length, time, and mass scales.

Restrictions

Only normal fluxes (Neumann data) can be prescribed.

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC unfix_flux

Default

None.

18.77.22  fix_modify AtC computes command

Syntax

fix_modify <AtC fixID> computes <add|delete> <per-atom compute-ID> <volume|number>

- AtC fixID = ID of fix atc instance
- computes = name of the AtC sub-command
- add or delete = add or delete the calculation of an equivalent continuum field for the specified per-atom compute as volume or number density quantity
• per-atom compute-ID = ID of a per-atom compute; fields can be calculated for all per-atom computes available in LAMMPS
• \textit{volume} or \textit{number} = select whether the created field is a per-unit-volume quantity or a per-atom quantity as weighted by kernel functions

\textbf{Examples}

\begin{verbatim}
compute virial all stress/atom
fix_modify AtC computes add virial volume
fix_modify AtC computes delete virial

compute centrosymmetry all centro/atom
fix_modify AtC computes add centrosymmetry number
\end{verbatim}

\textbf{Description}

Calculates continuum fields corresponding to specified per-atom \textit{computes} created by LAMMPS.

\textbf{Restrictions}

Must be used with \textit{fix atc hardy}. The per-atom compute must be specified before the corresponding continuum field can be requested.

\textbf{Related AtC commands}

• \textit{fix\_modify AtC command overview}
• \textit{fix\_modify AtC fields}
• \textit{compute}

\textbf{Default}

None.

\textbf{18.77.23 \textit{fix\_modify AtC fields} command}

\textbf{Syntax}

\begin{verbatim}
fix_modify <AtC fixID> fields <all|none>
fix_modify <AtC fixID> fields <add|delete> <list_of_fields>
\end{verbatim}

• AtC fixID = ID of \textit{fix atc} instance
• fields = name of the AtC sub-command
• \textit{all} or \textit{none} = output all or no fields
• \textit{add} or \textit{delete} = add or delete the listed output fields
• list\_of\_fields = one or more of the fields listed below:
- density: mass per unit volume
- displacement: displacement vector
- momentum: momentum per unit volume
- velocity: defined by momentum divided by density
- projected_velocity: simple kernel estimation of atomic velocities
- temperature: temperature derived from the relative atomic kinetic energy
- kinetic_temperature: temperature derived from the full kinetic energy
- number_density: simple kernel estimation of number of atoms per unit volume
- stress: Cauchy stress tensor for eulerian analysis (atom_element_map), or first Piola-Kirchhoff stress tensor for lagrangian analysis
- transformed_stress: first Piola-Kirchhoff stress tensor for eulerian analysis (atom_element_map), or Cauchy stress tensor for lagrangian analysis
- heat_flux: spatial heat flux vector for eulerian, or referential heat flux vector for lagrangian
- potential_energy: potential energy per unit volume
- kinetic_energy: kinetic energy per unit volume
- thermal_energy: thermal energy (kinetic energy - continuum kinetic energy) per unit volume
- internal_energy: total internal energy (potential + thermal) per unit volume
- energy: total energy (potential + kinetic) per unit volume
- number_density: number of atoms per unit volume
- eshelby_stress: configurational stress (energy-momentum) tensor defined by [Eshelby]
- vacancy_concentration: volume fraction of vacancy content
- type_concentration: volume fraction of a specific atom type

**Examples**

```
fix_modify AtC fields add velocity temperature
```

**Description**

Allows modification of the fields calculated and output by the AtC transfer class. The commands are cumulative, e.g.:

```
fix_modify AtC fields none
fix_modify AtC fields add velocity temperature
```

will only output the velocity and temperature fields.
Restrictions

Must be used with `fix atc hardy`. Currently, the stress and heat flux formulas are only correct for central force potentials, e.g. Lennard-Jones and EAM but not Stillinger-Weber.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC gradients`
- `fix_modify AtC rates`
- `fix_modify AtC computes`

Default

By default, no fields are output.

References

18.77.24 `fix_modify AtC gradients command`

Syntax

```
fix_modify <AtC fixID> gradients <add|delete> <list_of_fields>
```

- `AtC fixID` = ID of `fix atc` instance
- `gradients` = name of the AtC sub-command
- `add` or `delete` = select whether to add or delete calculation of gradients for the listed output fields
- `list_of_fields` = one or more of the fields listed below:
  - `density` : mass per unit volume
  - `displacement` : displacement vector
  - `momentum` : momentum per unit volume
  - `velocity` : defined by momentum divided by density
  - `projected_velocity` : simple kernel estimation of atomic velocities
  - `temperature` : temperature derived from the relative atomic kinetic energy
  - `kinetic_temperature` : temperature derived from the full kinetic energy
  - `number_density` : simple kernel estimation of number of atoms per unit volume
  - `stress` : Cauchy stress tensor for eulerian analysis (atom_element_map), or first Piola-Kirchhoff stress tensor for lagrangian analysis
  - `transformed_stress` : first Piola-Kirchhoff stress tensor for eulerian analysis (atom_element_map), or Cauchy stress tensor for lagrangian analysis
  - `heat_flux` : spatial heat flux vector for eulerian, or referential heat flux vector for lagrangian
  - `potential_energy` : potential energy per unit volume
- kinetic_energy : kinetic energy per unit volume
- thermal_energy : thermal energy (kinetic energy - continuum kinetic energy) per unit volume
- internal_energy : total internal energy (potential + thermal) per unit volume
- energy : total energy (potential + kinetic) per unit volume
- number_density : number of atoms per unit volume
- eshelby_stress : configurational stress (energy-momentum) tensor defined by [Eshelby]
- vacancy_concentration : volume fraction of vacancy content
- type_concentration : volume fraction of a specific atom type

Examples

```
fix_modify AtC gradients add temperature velocity stress
fix_modify AtC gradients delete velocity
```

Description

Requests calculation and output of gradients of the fields from the AtC transfer class. These gradients will be with regard to spatial or material coordinate for Eulerian or Lagrangian analysis, respectively, as specified by `fix_modify AtC atom_element_map`

Restrictions

Must be used with `fix atc hardy`.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC atom_element_map`
- `fix_modify AtC fields`
- `fix_modify AtC rates`

Default

None.
18.77.25 `fix_modify AtC kernel command`

Syntax

```
fix_modify <AtC fixID> kernel <type> <parameters>
```

- AtC fixID = ID of `fix atc` instance
- `kernel` = name of the AtC sub-command
- `type` = `step`, `cell`, `cubic_bar`, `cubic_cylinder`, `cubic_sphere`, `quartic_bar`, `quartic_cylinder`, or `quartic_sphere`

- the following parameter(s) are required for each kernel:
  - `step` : `<radius>`
  - `cell` : `<hx> <hy> <hz>` or `<h>`
  - `cubic_bar` : `<half_width>`
  - `cubic_cylinder` : `<radius>`
  - `cubic_sphere` : `<radius>`
  - `quartic_bar` : `<half_width>`
  - `quartic_cylinder` : `<radius>`
  - `quartic_sphere` : `<radius>`

Examples

```
fix_modify AtC kernel cell 1.0 1.0 1.0
fix_modify AtC kernel quartic_sphere 10.0
```

Description

Sets the localization kernel type and parameters for `fix atc hardy`.

Restrictions

Must be used with `fix atc hardy`. For bar kernel types, half-width oriented along x-direction. For cylinder kernel types, cylindrical axis is assumed to be in z-direction.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC fields`
- `fix_modify AtC gradients`
- `fix_modify AtC rates`
- `fix_modify AtC computes`
**Default**

None.

### 18.77.26 fix_modify AtC on_the_fly command

#### Syntax

```plaintext
fix_modify <AtC fixID> on_the_fly <bond|kernel> <on|off>
```

- **AtC fixID** = ID of `fix atc` instance
- **on_the_fly** = name of the AtC sub-command
- **bond or kernel** = specifies on-the-fly calculation of bond or kernel matrix elements
- **on or off** = activate or discontinue on-the-fly mode

#### Examples

```plaintext
fix_modify AtC on_the_fly bond on
fix_modify AtC on_the_fly kernel
fix_modify AtC on_the_fly kernel off
```

#### Description

Overrides normal mode of pre-calculating and storing bond pair-to-node and kernel atom-to-node matrices. If activated, it will calculate elements of these matrices during repeated calls of field computations (i.e. “on-the-fly”) and not store them for future use. The **on** flag is optional - if omitted, on_the_fly will be activated for the specified matrix. Can be deactivated using the **off** flag.

#### Restrictions

Must be used with `fix atc hardy`.

#### Related AtC commands

- `fix_modify AtC command overview`

#### Default

By default, on-the-fly calculation is not active (i.e. off). However, THE code does a memory allocation check to determine if it can store all needed bond and kernel matrix elements. If this allocation fails, on-the-fly will be activated.
18.77.27 fix_modify AtC rates command

Syntax

```
fix_modify <AtC fixID> rates <add|delete> <list_of_fields>
```

- AtC fixID = ID of fix atc instance
- rates = name of the AtC sub-command
- add or delete = select whether to add or delete calculation of rates for the listed output fields
- list_of_fields = one or more of the fields listed below:
  - density : mass per unit volume
  - displacement : displacement vector
  - momentum : momentum per unit volume
  - velocity : defined by momentum divided by density
  - projected_velocity : simple kernel estimation of atomic velocities
  - temperature : temperature derived from the relative atomic kinetic energy
  - kinetic_temperature : temperature derived from the full kinetic energy
  - number_density : simple kernel estimation of number of atoms per unit volume
  - stress : Cauchy stress tensor for eulerian analysis (atom_element_map), or first Piola-Kirchhoff stress tensor for lagrangian analysis
  - transformed_stress : first Piola-Kirchhoff stress tensor for eulerian analysis (atom_element_map), or Cauchy stress tensor for lagrangian analysis
  - heat_flux : spatial heat flux vector for eulerian, or referential heat flux vector for lagrangian
  - potential_energy : potential energy per unit volume
  - kinetic_energy : kinetic energy per unit volume
  - thermal_energy : thermal energy (kinetic energy - continuum kinetic energy) per unit volume
  - internal_energy : total internal energy (potential + thermal) per unit volume
  - energy : total energy (potential + kinetic) per unit volume
  - number_density : number of atoms per unit volume
  - eshelby_stress : configurational stress (energy-momentum) tensor defined by [Eshelby]
  - vacancy_concentration : volume fraction of vacancy content
  - type_concentration : volume fraction of a specific atom type
### Description

Requests calculation and output of rates (time derivatives) of the fields from the AtC transfer class. For Eulerian analysis (see `fix_modify AtC atom_element_map`) these rates are the partial time derivatives of the nodal fields, not the full (material) time derivatives.

### Restrictions

Must be used with `fix atc hardy`.

### Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC atom_element_map`
- `fix_modify AtC fields`
- `fix_modify AtC fields`

### Default

None.

### 18.77.28 fix_modify AtC initial command

**Syntax**

```
fix_modify <AtC fixID> initial <field> <nodeset> <constant|function>
```

- AtC fixID = ID of `fix atc` instance
- initial = name of the AtC sub-command
- field = field kind name valid for type of physics: `temperature` or `electron_temperature`
- nodeset = name of set of nodes to apply initial condition
- `constant` or `function` = value or name of function followed by its parameters
Examples

```latex
fix_modify AtC initial temperature groupNAME 10.
```

Description

Sets the initial values for the specified field at the specified nodes.

Restrictions

The keyword `all` is reserved and thus not available as nodeset name.

Related AtC commands

- `fix_modify AtC command overview`

Default

None.

18.77.29 fix_modify AtC internal_element_set command

Syntax

```latex
fix_modify <AtC fixID> internal_element_set <element_set_name>
```

- `AtC fixID = ID of fix atc instance`
- `internal_element_set = name of the AtC sub-command`
- `element_set_name = name of element set defining internal region, or off`

Examples

```latex
fix_modify AtC internal_element_set myElementSet
fix_modify AtC internal_element_set off
```

Description

Enables AtC to base the region for internal atoms to be an element set. If no ghost atoms are used, all the AtC atoms must be constrained to remain in this element set by the user, e.g., with walls. If boundary atoms are used in conjunction with Eulerian atom maps AtC will partition all atoms of a boundary or internal type to be of type internal if they are in the internal region or to be of type boundary otherwise.
Restrictions

If boundary atoms are used in conjunction with Eulerian atom maps, the Eulerian reset frequency must be an integer multiple of the Lammps reneighbor frequency.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC atom_element_map`
- `fix_modify AtC boundary type`

Default

`off`

18.77.30 fix_modify AtC internal_quadrature command

Syntax

```
fix_modify <AtC fixID> internal_quadrature <on|off> [region]
```

- AtC fixID = ID of `fix atc` instance
- internal_quadrature = name of the AtC sub-command
- on or off = select whether internal quadrature is enabled or not
- region = treat finite elements as within MD region (optional)

Examples

```
fix_modify AtC internal_quadrature off
```

Description

Command to use or not use atomic quadrature on internal elements fully filled with atoms. By turning the internal quadrature off these elements do not contribute to the governing PDE and the fields at the internal nodes follow the weighted averages of the atomic data.

Optional region tag specifies which finite element nodes will be treated as being within the MD region. This option is only valid with internal_quadrature off.
Related AtC commands

- fix_modify AtC command overview

Default

on.

18.77.31 fix_modify AtC kernel_bandwidth command

Syntax

fix_modify <AtC fixID> kernel_bandwidth <value>

- AtC fixID = ID of fix atc instance
- kernel_bandwidth = name of the AtC sub-command
- value = new bandwidth value

Examples

fix_modify AtC kernel_bandwidth 8

Description

Sets a maximum parallel bandwidth for the kernel functions during parallel communication. If the command is not issued, the default will be to assume the bandwidth of the kernel matrix corresponds to the number of sampling locations.

Restrictions

Only is used if kernel functions are being used.

Related AtC commands

- fix_modify AtC command overview

Default

Number of sample locations.
18.77.32 fix_modify AtC control lumped_lambda_solve command

Syntax

```
fix_modify <AtC fixID> control lumped_lambda_solve <on|off>
```

- AtC fixID = ID of fix atc instance
- control lumped_lambda_solve = name of the AtC sub-command
- on or off = Toggles state of lumped matrix

Examples

```
fix_modify AtC control lumped_lambda_solve on
```

Description

Command select whether to use or not use lumped matrix for lambda solve.

Restrictions

None.

Related AtC commands

- fix_modify AtC command overview

Default

off

18.77.33 fix_modify AtC control mask_direction command

Syntax

```
fix_modify <AtC fixID> control mask_direction <direction> <on|off>
```

- AtC fixID = ID of fix atc instance
- control mask_direction = name of the AtC sub-command
- direction = select direction
- on or off = Toggles state
Examples

```plaintext
fix_modify AtC control mask_direction 0 on
```

Description

Command to mask out certain dimensions from the atomic regulator

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`

18.77.34 fix_modify AtC mass_matrix command

Syntax

```plaintext
fix_modify <AtC fixID> mass_matrix <fe|md_fe>
```

- AtC fixID = ID of `fix atc` instance
- mass_matrix = name of the AtC sub-command
- `fe` or `md_fe` = activate/deactivate using the FE mass matrix in the MD region

Examples

```plaintext
fix_modify AtC mass_matrix fe
```

Description

Determines whether AtC uses the FE mass matrix based on Gaussian quadrature or based on atomic quadrature in the MD region. This is useful for fully overlapping simulations to improve efficiency.

Restrictions

Should not be used unless the FE region is contained within the MD region, otherwise the method will be unstable and inaccurate.
Related AtC commands

- fix_modify AtC command overview

Default

md_fe

18.77.35 fix_modify AtC material command

Syntax

```plaintext
fix_modify <AtC fixID> material <elementset_name> <material_id>
```

- AtC fixID = ID of fix atc instance
- material = name of the AtC sub-command
- elementset_name = name of the elementset
- material_id = ID of the material

Examples

```plaintext
fix_modify AtC material gap_region 1
```

Description

Sets the material model in `elementset_name` to be of type `material_id`.

Restrictions

The element set must already be created and the material must be specified in the material file given the the atc fix on construction

Related AtC commands

- fix_modify AtC command overview

Default

All elements default to the first material in the material file.
18.77.36 fix_modify AtC mesh add_to_nodeset command

Syntax

```
fix_modify <AtC fixID> mesh add_to_nodeset <id> <xmin> <xmax> <ymin> <ymax> <zmin> <zmax>
```

- AtC fixID = ID of fix atc instance
- mesh create_nodeset = name of the AtC sub-command
- id = id to assign to the collection of FE nodes
- <xmin> <xmax> <ymin> <ymax> <zmin> <zmax> = coordinates of the bounding box that contains the desired nodes to be added

Examples

```
fix_modify AtC mesh add_to_nodeset lbc -12.1 -11.9 -12 12 -12 12
```

Description

Command to add nodes to an already existing FE nodeset.

Restrictions

None

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC mesh create_nodeset

Default

Coordinates are assumed to be in lattice units.

18.77.37 fix_modify AtC mesh create command

Syntax

```
fix_modify <AtC fixID> mesh create <nx> <ny> <nz> <region-ID> <f|p> <f|p> <f|p>
```

- AtC fixID = ID of fix atc instance
- mesh create = name of the AtC sub-command
- nx ny nz = number of elements in x-, y-, and z-direction
- region-ID = ID of region that is to be meshed
• f or p = periodicity flags for x-, y-, and z-direction

**Examples**

```plaintext
fix_modify AtC mesh create 10 1 1 feRegion p p p
```

**Description**

Creates a uniform mesh in a rectangular region.

**Restrictions**

Creates only uniform rectangular grids in a rectangular region

**Related AtC commands**

- `fix_modify AtC command overview`
- `fix_modify AtC mesh quadrature`

**Default**

When created, the mesh defaults to gauss2 (2-point Gaussian) quadrature. Use the `fix_modify AtC mesh quadrature` command to change the quadrature style.

**18.77.38 fix_modify AtC mesh create_elementset command**

**Syntax**

```plaintext
fix_modify <AtC fixID> mesh create_elementset <id> <xmin> <xmax> <ymin> <ymax> <zmin> <zmax>
```

- AtC fixID = ID of `fix atc` instance
- mesh create_elementset = name of the AtC sub-command
- id = id to assign to the collection of FE nodes
- `<xmin> <xmax> <ymin> <ymax> <zmin> <zmax>` = coordinates of the bounding box that contains only the desired elements
Examples

```plaintext
fix_modify AtC mesh create_elementset middle -4.1 4.1 -100 100 -100 1100
```

Description

Command to assign an id to a set of FE elements to be used subsequently in defining material and mesh-based operations.

Restrictions

Only viable for rectangular grids.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC mesh delete_elements`
- `fix_modify AtC mesh nodeset_to_elementset`

Default

Coordinates are assumed to be in lattice units.

18.77.39 fix_modify AtC mesh create_faceset box command

Syntax

```plaintext
fix_modify <AtC fixID> mesh create_faceset <id> box <xmin> <xmax> <ymin> <ymax> <zmin> <zmax> <in|out> [units]
```

- `AtC fixID` = ID of `fix atc` instance
- `mesh create_faceset` = name of the AtC sub-command
- `id` = id to assign to the collection of FE faces
- `box` = use bounding box to define FE faces
- `<xmin> <xmax> <ymin> <ymax> <zmin> <zmax>` = coordinates of the bounding box that is coincident with the desired FE faces
- `<in|out>` = “in” gives inner faces to the box, “out” gives the outer faces to the box
- `units` = option to specify real as opposed to lattice units
Examples

```plaintext
fix_modify AtC mesh create_faceset obndy box -4.0 4.0 -12 12 -12 12 out
```

Description

Command to assign an id to a set of FE faces.

Restrictions

Only viable for rectangular grids.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC mesh create_faceset plane`

Default

The default options are units = lattice and the use of outer faces.

18.77.40 fix_modify AtC mesh create_faceset plane command

Syntax

```plaintext
fix_modify <AtC fixID> mesh create_faceset <id> plane <x|y|z> <val1> <x|y|z> <lval2> [units]
```

- `AtC fixID` = ID of fix atc instance
- `mesh create_faceset` = name of the AtC sub-command
- `id` = id to assign to the collection of FE faces
- `plane` = use plane to define faceset
- `<val1>,<val2>,<uval2>` = plane is specified as the xlylz=val1 plane bounded by the segments xlylz = [lval2, uval2]
- `units` = option to specify real as opposed to lattice units

Examples

```plaintext
fix_modify AtC mesh create_faceset xyplane plane y 0 x -4 0
```
**Description**

Command to assign an id to a set of FE faces.

**Restrictions**

Only viable for rectangular grids.

**Related AtC commands**

- `fix_modify AtC command overview`
- `fix_modify AtC mesh create_faceset box`

**Default**

The default options are units = lattice.

### 18.77.41 `fix_modify AtC mesh create_nodeset command`

**Syntax**

```plaintext
fix_modify <AtC fixID> mesh create_nodeset <id> <xmin> <xmax> <ymin> <ymax> <zmin> <zmax>
```

- `AtC fixID` = ID of `fix atc` instance
- `mesh create_nodeset` = name of the AtC sub-command
- `id` = id to assign to the collection of FE nodes
- `<xmin> <xmax> <ymin> <ymax> <zmin> <zmax>` = coordinates of the bounding box that contains only the desired nodes

**Examples**

```plaintext
fix_modify AtC mesh create_nodeset lbc -12.1 -11.9 -12 12 -12 12
```

**Description**

Command to assign an id to a set of FE nodes to be used subsequently in defining boundary conditions.
Restrictions

None

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC mesh add_to_nodeset`

Default

Coordinates are assumed to be in lattice units.

18.77.42 fix_modify AtC mesh delete_elements command

Syntax

```
fix_modify <AtC fixID> mesh delete_elements <id>
```

- `AtC fixID` = ID of `fix atc` instance
- `mesh create_elementset` = name of the AtC sub-command
- `id` = id of the element set

Examples

```
fix_modify AtC mesh delete_elements gap
```

Description

Deletes a group of elements from the mesh.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC mesh create_elementset`
- `fix_modify AtC mesh nodeset_to_elementset`
Default

None.

**18.77.43 fix_modify AtC mesh nodeset_to_elementset command**

**Syntax**

```
fix_modify <AtC fixID> mesh nodeset_to_elementset <nodeset_id> <elementset_id> <max/min>
```

- AtC fixID = ID of fix atc instance
- mesh nodeset_to_elementset = name of the AtC sub-command
- nodeset_id = id of desired nodeset from which to create the elementset
- elementset_id = id to assign to the collection of FE elements
- <max/min> = flag to choose either the maximal or minimal elementset

**Examples**

```
fix_modify AtC mesh nodeset_to_elementset myNodeset myElementset min
```

**Description**

Command to create an elementset from an existing nodeset. Either the minimal element set of elements with all nodes in the set, or maximal element set with all elements with at least one node in the set, can be created.

**Restrictions**

None.

**Related AtC commands**

- [fix_modify AtC command overview](#)
- [fix_modify AtC mesh create_elementset](#)
- [fix_modify AtC mesh delete_elements](#)

**Default**

Unless specified, the maximal element set is created.
18.77.44 fix_modify AtC mesh output command

Syntax

```
fix_modify <AtC fixID> mesh output <file_prefix>
```

- AtC fixID = ID of `fix atc` instance
- mesh output = name of the AtC sub-command
- file_prefix = prefix of various generated output files

Examples

```
fix_modify AtC mesh output meshData
```

Description

Command to output mesh and associated data: nodesets, facesets, and elementsets. This data is only output once upon initialization since currently the mesh is static. Creates binary (EnSight, “gold” format) output of mesh data.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`

Default

None.

18.77.45 fix_modify AtC mesh quadrature command

Syntax

```
fix_modify <AtC fixID> mesh quadrature <quad>
```

- AtC fixID = ID of `fix atc` instance
- mesh quadrature = name of the AtC sub-command
- quad = `nodal` or `gauss1` or `gauss2` or `gauss3` or `face`
Examples

```plaintext
fix_modify AtC mesh quadrature face
```

Description

(Re-)assigns the quadrature style for an existing mesh. When a mesh is created its quadrature method defaults to gauss2. Use this call to change it after the fact.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC mesh create`

Default

None.

18.77.46 fix_modify AtC mesh read command

Syntax

```plaintext
fix_modify <AtC fixID> mesh read <f|p> <f|p> <f|p>
```

- `AtC fixID` = ID of `fix atc` instance
- `mesh read` = name of the AtC sub-command
- `filename` = name of the file containing the mesh to be read
- `f or p` = periodicity flags for x-, y-, and z-direction (optional)

Examples

```plaintext
fix_modify AtC mesh read myComponent.mesh p p p
fix_modify AtC mesh read myOtherComponent.exo
```
Description

Reads a mesh from a text or exodus file, and assigns periodic boundary conditions if needed.

Restrictions

None

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC mesh create
- fix_modify AtC mesh write

Default

Periodicity flags are set to false (f) by default.

18.77.47  fix_modify AtC mesh write command

Syntax

```
fix_modify <AtC fixID> mesh write <f|p> <f|p> <f|p>
```

- AtC fixID = ID of fix atc instance
- mesh write = name of the AtC sub-command
- filename = name of the file containing the mesh to be write

Examples

```
fix_modify AtC mesh write myMesh.mesh
```

Description

Writes a mesh to a text file.

Restrictions

None
Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC mesh create
- fix_modify AtC mesh read

Default

None.

18.77.48 fix_modify AtC output command

Syntax

```latex
\texttt{fix_modify <AtC fixID> output <filename_prefix> <frequency> \{text\|full_\→text\|binary\|vector_components\|tensor_components\}\nfix_modify <AtC fixID> output index \{step\|time\}\n```

- AtC fixID = ID of \texttt{fix atc} instance
- output or output index = name of the AtC sub-command
- filename_prefix = prefix for data files (for \texttt{output})
- frequency = frequency of output in time-steps (for \texttt{output})
- optional keywords for \texttt{output}:
  - text = creates text output of index, step and nodal variable values for unique nodes
  - full_text = creates text output index, nodal id, step, nodal coordinates and nodal variable values for unique and image nodes
  - binary = creates binary EnSight output
  - vector_components = outputs vectors as scalar components
  - tensor_components = outputs tensor as scalar components (for use with ParaView)
- step or time = index output by step or by time (for \texttt{output index})

Examples

```latex
\texttt{fix_modify AtC output heatFE 100 \nfix_modify AtC output hardyFE 1 text tensor_components \nfix_modify AtC output hardyFE 10 text binary tensor_components \nfix_modify AtC output index step}\n```
Description

Creates text and/or binary (EnSight, “gold” format) output of nodal/mesh data which is transfer/physics specific. Output indexing by step or time is possible.

Restrictions

None.

Related AtC commands

- fix_modify AtC command overview
- fix atc command

Default

No default format. Output indexed by time.

18.77.49 fix_modify AtC output boundary_integral command

Syntax

```
fix_modify <AtC fixID> output boundary_integral <fieldname> faceset [name]
```

- AtC fixID = ID of fix atc instance
- output boundary_integral = name of the AtC sub-command
- fieldname = name of hardy field
- faceset = required keyword
- name= name of faceset

Examples

```
fix_modify AtC output boundary_integral stress faceset loop1
```

Description

Calculates a surface integral of the given field dotted with the outward normal of the faces and puts output in the “GLOBALS” file.
Restrictions

Must be used with the hardy/field type of *fix atc*

Related AtC commands

- *fix_modify AtC command overview*

Default

None.

**18.77.50 fix_modify AtC output contour_integral command**

Syntax

```plaintext
fix_modify <AtC fixID> output contour_integral <fieldname> faceset <name> [axis x|y|z]
```

- AtC fixID = ID of *fix atc* instance
- output contour_integral = name of the AtC sub-command
- fieldname = name of hardy field
- faceset = required keyword
- name = name of faceset
- axis x or axis y or axis z = (optional)

Examples

```plaintext
fix_modify AtC output contour_integral stress faceset loop1
```

Description

Calculates a surface integral of the given field dotted with the outward normal of the faces and puts output in the “GLOBALS” file.

Restrictions

Must be used with the hardy/field type of *fix atc*
Related AtC commands

- `fix_modify AtC command overview`

Default

None.

18.77.51 `fix_modify AtC output nodeset command`

Syntax

```
fix_modify <AtC fixID> output nodeset <nodeset_name> <operation>
```

- AtC fixID = ID of `fix atc` instance
- output nodeset = name of the AtC sub-command
- nodeset_name = name of nodeset to be operated on
- operation = `sum`
  - `sum` = creates nodal sum over nodes in specified nodeset

Examples

```
fix_modify AtC output nodeset nset1 sum
```

Description

Performs operation over the nodes belonging to specified nodeset and outputs resulting variable values to GLOBALS file.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix atc command`
**Default**

None.

### 18.77.52 fix_modify AtC output volume_integral command

**Syntax**

```
fix_modify <AtC fixID> output volume_integral <elementset_name> <field>
```

- **AtC fixID** = ID of fix atc instance
- **output volume_integral** = name of the AtC sub-command
- **elementset_name** = name of elementset to be integrated over
- **fieldname** = name of field to integrate

**Examples**

```
fix_modify AtC output volume_integral eset1 mass_density
```

**Description**

Performs volume integration of specified field over elementset and outputs resulting variable values to GLOBALS file.

**Restrictions**

None.

**Related AtC commands**

- `fix_modify AtC command overview`
- `fix atc command`

**Default**

None.

### 18.77.53 fix_modify AtC pair_interactions command

### 18.77.54 fix_modify AtC bond_interactions command

**Syntax**

```
fix_modify <AtC fixID> pair_interactions <on|off>
fix_modify <AtC fixID> bond_interactions <on|off>
```
• AtC fixID = ID of fix atc instance
• pair_interactions or bond_interactions = name of the AtC sub-command
• on or off = activate or deactivate

Examples

```
fix_modify AtC pair_interactions off
fix_modify AtC bond_interactions on
```

Description

Include bonds and/or pairs in stress and heat flux computations.

Restrictions

None.

Related AtC commands

• fix_modify AtC command overview

Default

pair_interactions: on, bond_interactions: off

18.77.55 fix_modify AtC poisson_solver command

Syntax

```
fix_modify <AtC fixID> poisson_solver mesh create <nx> <ny> <nz> <region-ID> <f|p>
           <f|p> <f|p>
```

• AtC fixID = ID of fix atc instance
• poisson_solver = name of the AtC sub-command
• nx ny nz = number of elements in x, y, and z
• region-id = id of region to be meshed
• f or p = periodicity flags for x, y, and z
Examples

```bash
fix_modify AtC poisson_solver mesh create 10 1 1 feRegion p p p
```

Description

Creates a uniform mesh in a rectangular region.

Restrictions

Creates only uniform rectangular grids in rectangular regions.

Related AtC commands

- `fix_modify AtC command overview`

Default

None.

18.77.56 fix_modify AtC read_restart command

Syntax

```bash
fix_modify <AtC fixID> read_restart <file_name>
```

- `AtC fixID` = ID of `fix atc` instance
- `read_restart` = name of the AtC sub-command
- `file_name` = name of AtC restart file

Examples

```bash
fix_modify AtC read_restart restart.mydata.AtC
```

Description

Reads the current state of the AtC fields from a named text-based restart file.
Restrictions

The restart file only contains fields and their time derivatives. The reference positions of the atoms and the commands that initialize the fix are not saved e.g. an identical mesh containing the same atoms will have to be recreated.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC write_restart`

Default

None.

18.77.57 `fix_modify AtC remove_molecule` command

Syntax

```
fix_modify <AtC fixID> remove_molecule <tag>
```

- `AtC fixID` = ID of `fix atc` instance
- `remove_molecule` = name of the AtC sub-command
- `tag` = tag for tracking a molecule

Examples

```
fix_modify AtC remove_molecule water
```

Description

Removes tag designated for tracking a specified set of molecules.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC add_species`
- `fix_modify AtC add_molecule`
- `fix_modify AtC remove_species`
Default
None.

18.77.58 fix_modify AtC remove_source command

Syntax

fix_modify <AtC fixID> remove_source <field> <element_set>

- AtC fixID = ID of fix atc instance
- remove_source = name of the AtC sub-command
- field = field kind name valid for type of physics: temperature or electron_temperature
- element_set = name of set of elements

Examples

fix_modify AtC remove_source temperature groupNAME

Description

Remove a domain source.

Restrictions

The keyword all is reserved and thus not available as element_set name.

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC source

Default

None.

18.77.59 fix_modify AtC remove_species command

Syntax

fix_modify <AtC fixID> remove_species <tag>

- AtC fixID = ID of fix atc instance
- remove_species = name of the AtC sub-command
- tag = tag for tracking a species
Examples

```bash
fix_modify AtC remove_species gold
```

Description

Removes tag designated for tracking a specified species.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC add_species`
- `fix_modify AtC add_molecule`
- `fix_modify AtC remove_molecule`

Default

None.

18.77.60 `fix_modify AtC reset_atomic_reference_positions` command

Syntax

```bash
fix_modify <AtC fixID> reset_atomic_reference_positions
```

- AtC fixID = ID of `fix atc` instance
- `reset_atomic_reference_positions` = name of the AtC sub-command

Examples

```bash
fix_modify AtC reset_atomic_reference_positions
```
Description

Resets the atomic positions ATC uses to perform point to field operations. In can be used to use perfect lattice sites in ATC but a thermalized or deformed lattice in LAMMPS.

Restrictions

None.

Related ATC commands

- `fix_modify AtC command overview`

Default

None

18.77.61  fix_modify AtC reset_time command

Syntax

```
fix_modify <AtC fixID> reset_time <value>
```

- `AtC fixID = ID of fix atc instance`
- `reset_time = name of the AtC sub-command`
- `value = new time value`

Examples

```
fix_modify AtC reset_time 0.0
```

Description

Resets the simulation time counter.

Restrictions

None.
Related AtC commands

- `fix_modify AtC command overview`

Default

None

18.77.62 fix_modify AtC sample_frequency command

Syntax

```plaintext
fix_modify <AtC fixID> sample_frequency <freq>
```

- AtC fixID = ID of `fix atc` instance
- sample_frequency = name of the AtC sub-command
- freq = frequency to sample fields in number of steps

Examples

```plaintext
fix_modify AtC sample_frequency 10
```

Description

Specifies a frequency at which fields are computed for the case where time filters are being applied.

Restrictions

Must be used with `fix atc hardy` and is only relevant when time filters are being used.

Related AtC commands

- `fix_modify AtC command overview`

Default

None.
18.77.63 fix_modify AtC set reference_potential_energy command

Syntax

```
fix_modify <AtC fixID> set reference_potential_energy [value|filename]
```

- AtC fixID = ID of fix atc instance
- set reference_potential_energy = name of the AtC sub-command
- value = optional user specified zero point for PE in native LAMMPS energy units
- filename = optional user specified string for file of nodal PE values to be read-in

Examples

```
fix_modify AtC set reference_potential_energy
fix_modify AtC set reference_potential_energy -0.05
fix_modify AtC set reference_potential_energy myPEvalues
```

Description

Used to set various quantities for the post-processing algorithms. It sets the zero point for the potential energy density using the value provided for all nodes, or from the current configuration of the lattice if no value is provided, or values provided within the specified filename.

Restrictions

Must be used with fix atc hardy or fix atc field.

Related AtC commands

- fix_modify AtC command overview

Default

Defaults to the LAMMPS zero point i.e. isolated atoms.

18.77.64 fix_modify AtC source command

Syntax

```
fix_modify <AtC fixID> source <field> <element_set> value|function
```

- AtC fixID = ID of fix atc instance
- source = name of the AtC sub-command
- field = field kind name valid for type of physics: temperature or electron_temperature
- element_set = name of set of elements

18.77. fix_modify AtC commands
• value or function = value or name of function followed by its parameters

Examples

```bash
fix_modify AtC source temperature middle temporal_ramp 10.0 0.0
```

Description

Add domain sources to the mesh. The units are consistent with LAMMPS’s units for mass, length and time and are defined by the PDE being solved, e.g. for thermal transfer the balance equation is for energy and source is energy per time.

Restrictions

The keyword all is reserved and thus not available as element_set name.

Related AtC commands

• fix_modify AtC command overview
• fix_modify AtC remove_source

Default

None.

18.77.65 fix_modify AtC source_integration command

Syntax

```bash
fix_modify <AtC fixID> source_integration <fe|atom>
```

• AtC fixID = ID of fix atc instance
• source_integration = name of the AtC sub-command
• fe or atom = (undocumented)

Examples

```bash
fix_modify AtC source_integration atom
```
Description
(undocumented)

Restrictions
None.

Related AtC commands

- fix_modify AtC command overview

Default

Default is $fe$

18.77.66 fix_modify AtC temperature_definition command

Syntax

```
fix_modify <AtC fixID> temperature_definition <kinetic|total>
```

- AtC fixID = ID of $fix atc$ instance
- temperature_definition = name of the AtC sub-command
- $kinetic$ or $total$ = (undocumented)

Examples

```
fix_modify AtC temperature_definition kinetic
```

Description

Change the definition for the atomic temperature used to create the finite element temperature. The kinetic option is based only on the kinetic energy of the atoms while the total option uses the total energy (kinetic + potential) of an atom.

Restrictions

This command is only valid when using thermal coupling. Also, while not a formal restriction, the user should ensure that associating a potential energy with each atom makes physical sense for the total option to be meaningful.
Related AtC commands

- `fix_modify AtC command overview`

Default

`kinetic`

18.77.67 fix_modify AtC filter command

Syntax

```
fix_modify <AtC fixID> filter <on|off|equilibrate>
```

- `AtC fixID` = ID of `fix atc` instance
- `filter` = name of the AtC sub-command
- `on` or `off` or `equilibrate` = Select state of filter

Examples

```
fix_modify AtC filter on
```

Description

Filters the MD dynamics to construct a more appropriate continuous field. Equilibrating first filters the time derivatives without changing the dynamics to provide a better initial condition to the filtered dynamics.

Restrictions

Only for use with these specific transfers: thermal, two_temperature

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC filter scale`
- `fix_modify AtC equilibrium_start`
Default

off

**18.77.68 fix_modify AtC time_integration command**

**Syntax**

```
fix_modify <AtC fixID> time_integration <descriptor>
```

- `AtC fixID` = ID of `fix atc` instance
- `time_integration` = name of the AtC sub-command
- `descriptor` = `gear` or `fractional_step` or `verlet`

**Examples**

```
fix_modify AtC time_integration fractional_step
```

**Description**

Command to select the thermal or momentum time integration.

Options for thermal time integration:

- `gear` atomic velocity update with second order Verlet, nodal temperature update with third or fourth order Gear, thermostats based on controlling power
- `fractional_step` atomic velocity update with second order Verlet, mixed nodal temperature update, $3/4$ Gear for continuum and $2$ Verlet for atomic contributions, thermostats based on controlling discrete energy changes

Options for momentum time integration:

- `verlet` atomic velocity update with second order Verlet, nodal temperature update with second order Verlet, kinetostats based on controlling force
- `fractional_step` atomic velocity update with second order Verlet, mixed nodal momentum update, second order Verlet for continuum and exact second order Verlet for atomic contributions, kinetostats based on controlling discrete momentum changes
- `gear` atomic velocity update with second order Verlet, nodal temperature update with third or fourth order Gear, kinetostats based on controlling power.
Restrictions

None.

Related AtC commands

• fix_modify AtC command overview

Default

None.

18.77.69 fix_modify AtC track_displacement command

Syntax

fix_modify <AtC fixID> track_displacement <on|off>

• AtC fixID = ID of fix atc instance
• track_displacement = name of the AtC sub-command
• on or off = (undocumented)

Examples

fix_modify AtC track_displacement on

Description

Determines whether displacement is tracked or not. For solids problems this is a useful quantity, but for fluids it is not relevant.

Restrictions

Some constitutive models require the displacement field.

Related AtC commands

• fix_modify AtC command overview
18.77.70  fix_modify AtC unfix command

Syntax

fix_modify <AtC fixID> unfix <field> <nodeset>

- AtC fixID = ID of fix atc instance
- unfix = name of the AtC sub-command
- field = field kind name valid for type of physics: temperature or electron_temperature
- nodeset = name of set of nodes to apply boundary condition

Examples

fix_modify AtC unfix temperature groupNAME

Description

Removes constraint on field values for specified nodes.

Restrictions

The keyword all is reserved and thus not available as nodeset name.

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC fix

Default

None.

18.77.71  fix_modify AtC unfix_flux command

Syntax

fix_modify <AtC fixID> unfix_flux <field> <face_set> <value|function>

- AtC fixID = ID of fix atc instance
- unfix_flux = name of the AtC sub-command
• field = field kind name valid for type of physics: \textit{temperature} or \textit{electron_temperature}
• face_set = name of set of element faces

Examples

\begin{verbatim}
fix_modify AtC unfix_flux temperature faceSet
\end{verbatim}

Description

Command for removing prescribed normal fluxes e.g. heat_flux, stress.

Restrictions

None.

Related AtC commands

• \texttt{fix_modify AtC} command overview
• \texttt{fix_modify AtC fix_flux}

Default

None.

18.77.72 \texttt{fix_modify AtC write_atom_weights command}

Syntax

\begin{verbatim}
fix_modify <AtC fixID> write_atom_weights <filename> <frequency>
\end{verbatim}

• AtC fixID = ID of \texttt{fix atc} instance
• write_atom_weights = name of the AtC sub-command
• filename = name of file that atomic weights are written to
• frequency = how often writes will occur

Examples

\begin{verbatim}
fix_modify AtC write_atom_weights atm_wt_file.txt 10
\end{verbatim}
Description

Command for writing the values of atomic weights to a specified file.

Restrictions

None.

Related AtC commands

- fix_modify AtC command overview

Default

None

18.77.73 fix_modify AtC write_restart command

Syntax

```
fix_modify <AtC fixID> write_restart <file_name>
```

- AtC fixID = ID of fix atc instance
- write_restart = name of the AtC sub-command
- file_name = name of AtC restart file

Examples

```
fix_modify AtC write_restart restart.mydata.AtC
```

Description

Dumps the current state of the fields to a named text-based restart file. This done when the command is invoked and not repeated, unlike the otherwise similar LAMMPS command.

Restrictions

None.
Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC read_restart

Default

None.

18.78 fix momentum command

Accelerator Variants: momentum/kk

18.79 fix momentum/chunk command

18.79.1 Syntax

```
fix ID group-ID momentum N keyword values ...
```

- ID, group-ID are documented in fix command
- momentum = style name of this fix command
- N = adjust the momentum every this many timesteps one or more keyword/value pairs may be appended
- keyword = linear or angular or rescale
  
  fix ID group-ID momentum/chunk N chunkID keyword values ...

- ID, group-ID are documented in fix command
- momentum/chunk = style name of this fix command
- N = adjust the momentum per chunk every this many timesteps
- chunkID = ID of compute chunk/atom command
  
  one or more keyword/value pairs may be appended
- keyword = linear or angular or rescale

  linear values = xflag yflag zflag
  
  xflag,yflag,zflag = 0/1 to exclude/include each dimension

  angular values = none

  rescale values = none
18.79.2 Examples

```
fix 1 all momentum 1 linear 1 1 0
fix 1 all momentum 1 linear 1 1 1 rescale
fix 1 all momentum 100 linear 1 1 1 angular
fix 1 all momentum/chunk 100 molchunk linear 1 1 1 angular
```

18.79.3 Description

Fix momentum zeroes the linear and/or angular momentum of the group of atoms every N timesteps by adjusting the velocities of the atoms. Fix momentum/chunk works equivalently, but operates on a per-chunk basis.

One (or both) of the linear or angular keywords must be specified.

If the linear keyword is used, the linear momentum is zeroed by subtracting the center-of-mass velocity of the group or chunk from each atom. This does not change the relative velocity of any pair of atoms. One or more dimensions can be excluded from this operation by setting the corresponding flag to 0.

If the angular keyword is used, the angular momentum is zeroed by subtracting a rotational component from each atom.

This command can be used to insure the entire collection of atoms (or a subset of them) does not drift or rotate during the simulation due to random perturbations (e.g. fix langevin thermostatting).

The rescale keyword enables conserving the kinetic energy of the group or chunk of atoms by rescaling the velocities after the momentum was removed.

Note that the velocity command can be used to create initial velocities with zero aggregate linear and/or angular momentum.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

18.79.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
18.79.5 Restrictions

Fix momentum/chunk is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

```

- ID, group-ID are documented in fix command
- move = style name of this fix command
- style = linear or wiggle or rotate or variable
  
  linear args = Vx Vy Vz
  Vx,Vy,Vz = components of velocity vector (velocity units), any component can be specified as NULL

  wiggle args = Ax Ay Az period
  Ax,Ay,Az = components of amplitude vector (distance units), any component can be specified as NULL
  period = period of oscillation (time units)

  rotate args = Px Py Pz Rx Ry Rz period
  Px,Py,Pz = origin point of axis of rotation (distance units)
  Rx,Ry,Rz = axis of rotation vector
  period = period of rotation (time units)

  variable args = v_dx v_dy v_dz v_vx v_vy v_vz
  v_dx,v_dy,v_dz = 3 variable names that calculate x,y,z displacement as function of time, any component can be specified as NULL
  v_vx,v_vy,v_vz = 3 variable names that calculate x,y,z velocity as function of time, any component can be specified as NULL

- zero or more keyword/value pairs may be appended
- keyword = units
  
  units value = box or lattice
18.80.2 Examples

```
fix 1 boundary move wiggle 3.0 0.0 0.0 1.0 units box
fix 2 boundary move rotate 0.0 0.0 0.0 0.0 0.0 1.0 5.0
fix 2 boundary move variable v_myx v_myy NULL v_VX v_VY NULL
```

18.80.3 Description

Perform updates of position and velocity for atoms in the group each timestep using the specified settings or formulas, without regard to forces on the atoms. This can be useful for boundary or other atoms, whose movement can influence nearby atoms.

**Note:** The atoms affected by this fix should not normally be time integrated by other fixes (e.g. `fix nve`, `fix nvt`), since that will change their positions and velocities twice.

**Note:** As atoms move due to this fix, they will pass through periodic boundaries and be remapped to the other side of the simulation box, just as they would during normal time integration (e.g. via the `fix nve` command). It is up to you to decide whether periodic boundaries are appropriate with the kind of atom motion you are prescribing with this fix.

**Note:** As discussed below, atoms are moved relative to their initial position at the time the fix is specified. These initial coordinates are stored by the fix in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this fix by using the `set image` command.

The **linear** style moves atoms at a constant velocity, so that their position $X = (x,y,z)$ as a function of time is given in vector notation as

$$X(t) = X_0 + V \times \delta$$

where $X_0 = (x_0,y_0,z_0)$ is their position at the time the fix is specified, $V$ is the specified velocity vector with components $(V_x,V_y,V_z)$, and $\delta$ is the time elapsed since the fix was specified. This style also sets the velocity of each atom to $V = (V_x,V_y,V_z)$. If any of the velocity components is specified as NULL, then the position and velocity of that component is time integrated the same as the `fix nve` command would perform, using the corresponding force component on the atom.

**Note** that the **linear** style is identical to using the **variable** style with an equal-style variable that uses the `vdisplace()` function. E.g.

```
variable V equal 10.0
variable x equal vdisplace(0.0,$V$
fix 1 boundary move variable v_x NULL NULL v_V NULL NULL
```

The **wiggle** style moves atoms in an oscillatory fashion, so that their position $X = (x,y,z)$ as a function of time is given in vector notation as

$$X(t) = X_0 + A \sin(\omega \delta)$$

where $X_0 = (x_0,y_0,z_0)$ is their position at the time the fix is specified, $A$ is the specified amplitude vector with components $(A_x,A_y,A_z)$, $\omega$ is $2 \pi / \text{period}$, and $\delta$ is the time elapsed since the fix was specified. This style also
sets the velocity of each atom to the time derivative of this expression. If any of the amplitude components is specified as NULL, then the position and velocity of that component is time integrated the same as the `fix nve` command would perform, using the corresponding force component on the atom.

Note that the `wiggle` style is identical to using the `variable` style with `equal-style variables` that use the `swiggle()` and `cwiggle()` functions. E.g.

```
variable A equal 10.0
variable T equal 5.0
variable omega equal 2.0*PI/$T
variable x equal swiggle(0.0,$A,$T)
variable v equal v_omega*($A-cwiggle(0.0,$A,$T))
fix 1 boundary move variable v_x NULL NULL v_v NULL NULL
```

The `rotate` style rotates atoms around a rotation axis \( R = (Rx,Ry,Rz) \) that goes through a point \( P = (Px,Py,Pz) \). The period of the rotation is also specified. The direction of rotation for the atoms around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along \( R \), then your fingers wrap around the axis in the direction of rotation.

This style also sets the velocity of each atom to \( \omega \times R_{\perp} \) where \( \omega \) is its angular velocity around the rotation axis and \( R_{\perp} \) is a perpendicular vector from the rotation axis to the atom. If the defined `atom_style` assigns an angular velocity or angular momentum or orientation to each atom (`atom styles` sphere, ellipsoid, line, tri, body), then those properties are also updated appropriately to correspond to the atom’s motion and rotation over time.

The `variable` style allows the position and velocity components of each atom to be set by formulas specified via the `variable` command. Each of the 6 variables is specified as an argument to the fix as `v_name`, where name is the variable name that is defined elsewhere in the input script.

Each variable must be of either the `equal` or `atom` style. `Equal`-style variables compute a single numeric quantity, that can be a function of the timestep as well as of other simulation values. `Atom`-style variables compute a numeric quantity for each atom, that can be a function per-atom quantities, such as the atom’s position, as well as of the timestep and other simulation values. Note that this fix stores the original coordinates of each atom (see note below) so that per-atom quantity can be used in an atom-style variable formula. See the `variable` command for details.

The first 3 variables \( (v_{dx},v_{dy},v_{dz}) \) specified for the `variable` style are used to calculate a displacement from the atom’s original position at the time the fix was specified. The second 3 variables \( (v_{vx},v_{vy},v_{vz}) \) specified are used to compute a velocity for each atom.

Any of the 6 variables can be specified as NULL. If both the displacement and velocity variables for a particular \( x,y,z \) component are specified as NULL, then the position and velocity of that component is time integrated the same as the `fix nve` command would perform, using the corresponding force component on the atom. If only the velocity variable for a component is specified as NULL, then the displacement variable will be used to set the position of the atom, and its velocity component will not be changed. If only the displacement variable for a component is specified as NULL, then the velocity variable will be used to set the velocity of the atom, and the position of the atom will be time integrated using that velocity.

The `units` keyword determines the meaning of the distance units used to define the `linear` velocity and `wiggle` amplitude and `rotate` origin. This setting is ignored for the `variable` style. A `box` value selects standard units as defined by the `units` command, e.g. velocity in Angstroms/fs and amplitude and position in Angstroms for units = real. A `lattice` value means the velocity units are in lattice spacings per time and the amplitude and position are in lattice spacings. The `lattice` command must have been previously used to define the lattice spacing. Each of these 3 quantities may be dependent on the \( x,y,z \) dimension, since the lattice spacings can be different in \( x,y,z \).
18.80.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the original coordinates of moving atoms to binary restart files, as well as the initial timestep, so that the motion can be continuous in a restarted simulation. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** Because the move positions are a function of the current timestep and the initial timestep, you cannot reset the timestep to a different value after reading a restart file, if you expect a fix move command to work in an uninterrupted fashion.

None of the fix_modify options are relevant to this fix.

This fix produces a per-atom array which can be accessed by various output commands. The number of columns for each atom is 3, and the columns store the original unwrapped x,y,z coords of each atom. The per-atom values can be accessed on any timestep.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

For rRESPA time integration, this fix adjusts the position and velocity of atoms on the outermost rRESPA level.

- ID, group-ID are documented in fix command
- mscg = style name of this fix command
- N = envoke this fix every this many timesteps
- zero or more keyword/value pairs may be appended
- keyword = range or name or max
range arg = on or off
  on = range finding functionality is performed
  off = force matching functionality is performed
name args = name1 ... nameN
  name1,...,nameN = string names for each atom type (1-Ntype)
max args = maxb maxa maxd
  maxb,maxa,maxd = maximum bonds/angles/dihedrals per atom

18.81.2 Examples

fix 1 all mscg 1
fix 1 all mscg 1 range name A B
fix 1 all mscg 1 max 4 8 20

18.81.3 Description

This fix applies the Multi-Scale Coarse-Graining (MSCG) method to snapshots from a dump file to generate potentials for coarse-grained simulations from all-atom simulations, using a force-matching technique (Izvekov, Noid).

It makes use of the MS-CG library, written and maintained by Greg Voth’s group at the University of Chicago, which is freely available on their MS-CG GitHub site. See instructions on obtaining and installing the MS-CG library in the src/MSCG/README file, which must be done before you build LAMMPS with this fix command and use the command in a LAMMPS input script.

An example script using this fix is provided the examples/mscg directory.

The general workflow for using LAMMPS in conjunction with the MS-CG library to create a coarse-grained model and run coarse-grained simulations is as follows:

1. Perform all-atom simulations on the system to be coarse grained.
2. Generate a trajectory mapped to the coarse-grained model.
3. Create input files for the MS-CG library.
4. Run the range finder functionality of the MS-CG library.
5. Run the force matching functionality of the MS-CG library.
6. Check the results of the force matching.
7. Run coarse-grained simulations using the new coarse-grained potentials.

This fix can perform the range finding and force matching steps 4 and 5 of the above workflow when used in conjunction with the rerun command. It does not perform steps 1-3 and 6-7.

Step 2 can be performed using a Python script (what is the name?) provided with the MS-CG library which defines the coarse-grained model and converts a standard LAMMPS dump file for an all-atom simulation (step 1) into a LAMMPS dump file which has the positions of and forces on the coarse-grained beads.

In step 3, an input file named “control.in” is needed by the MS-CG library which sets parameters for the range finding and force matching functionalities. See the examples/mscg/control.in file as an example. And see the documentation provided with the MS-CG library for more info on this file.

When this fix is used to perform steps 4 and 5, the MS-CG library also produces additional output files. The range finder functionality (step 4) outputs files defining pair and bonded interaction ranges. The force matching functionality (step 5) outputs tabulated force files for every interaction in the system. Other diagnostic files can also be output depending on the parameters in the MS-CG library input script. Again, see the documentation provided with the MS-CG library for more info.
The *range* keyword specifies which MS-CG library functionality should be invoked. If *on*, the step 4 range finder functionality is invoked. *off*, the step 5 force matching functionality is invoked.

If the *name* keyword is used, string names are defined to associate with the integer atom types in LAMMPS. *Ntype* names must be provided, one for each atom type (1-Ntype).

The *max* keyword specifies the maximum number of bonds, angles, and dihedrals a bead can have in the coarse-grained model.

### 18.81.4 Restrictions

This fix is part of the MSCG package. It is only enabled if LAMMPS was built with that package. See the [Build package doc page](#) for more info.

The MS-CG library uses C++11, which may not be supported by older compilers. The MS-CG library also has some additional numeric library dependencies, which are described in its documentation.

Currently, the MS-CG library is not setup to run in parallel with MPI, so this fix can only be used in a serial LAMMPS build and run on a single processor.

### 18.81.5 Related commands

```

- ID, group-ID are documented in *fix* command
- *msst* = style name of this fix
- *dir* = x or y or z
- *shockvel* = shock velocity (strictly positive, distance/time units)
- zero or more keyword value pairs may be appended
- keyword = *q* or *mu* or *p0* or *v0* or *e0* or *tscale* or *beta* or *dftb*
### Examples

```plaintext
fix 1 all msst y 100.0 q 1.0e5 mu 1.0e5
fix 2 all msst z 50.0 q 1.0e4 mu 1.0e4 v0 4.3419e+03 p0 3.7797e+03 e0 -9.72360e+02 tscale 0.01
fix 1 all msst y 100.0 q 1.0e5 mu 1.0e5 dftb yes beta 0.5
```

### Description

This command performs the Multi-Scale Shock Technique (MSST) integration to update positions and velocities each timestep to mimic a compressive shock wave passing over the system. See [Reed](#) for a detailed description of this method. The MSST varies the cell volume and temperature in such a way as to restrain the system to the shock Hugoniot and the Rayleigh line. These restraints correspond to the macroscopic conservation laws dictated by a shock front. `shockvel` determines the steady shock velocity that will be simulated.

To perform a simulation, choose a value of `q` that provides volume compression on the timescale of 100 fs to 1 ps. If the volume is not compressing, either the shock speed is chosen to be below the material sound speed or `p0` has been chosen inaccurately. Volume compression at the start can be sped up by using a non-zero value of `tscale`. Use the smallest value of `tscale` that results in compression.

Under some special high-symmetry conditions, the pressure (volume) and/or temperature of the system may oscillate for many cycles even with an appropriate choice of mass-like parameter `q`. Such oscillations have physical significance in some cases. The optional `mu` keyword adds an artificial viscosity that helps break the system symmetry to equilibrate to the shock Hugoniot and Rayleigh line more rapidly in such cases.

The keyword `tscale` is a factor between 0 and 1 that determines what fraction of thermal kinetic energy is converted to compressive strain kinetic energy at the start of the simulation. Setting this parameter to a non-zero value may assist in compression at the start of simulations where it is slow to occur.

If keywords `e0`, `p0`, or `v0` are not supplied, these quantities will be calculated on the first step, after the energy specified by `tscale` is removed. The value of `e0` is not used in the dynamical equations, but is used in calculating the deviation from the Hugoniot.

The keyword `beta` is a scaling term that can be added to the MSST ionic equations of motion to account for drift in the conserved quantity during long timescale simulations, similar to a Berendsen thermostat. See [Reed](#) and [Goldman](#) for more details. The value of `beta` must be between 0.0 and 1.0 inclusive. A value of 0.0 means no contribution, a value of 1.0 means a full contribution.

Values of shockvel less than a critical value determined by the material response will not have compressive solutions. This will be reflected in lack of significant change of the volume in the MSST.

For all pressure styles, the simulation box stays orthogonal in shape. Parrinello-Rahman boundary conditions (tilted box) are supported by LAMMPS, but are not implemented for MSST.
This fix computes a temperature and pressure and potential energy each timestep. To do this, the fix creates its own computes of style “temp” “pressure”, and “pe”, as if these commands had been issued:

```plaintext
compute fix-ID_MSST_temp all temp
compute fix-ID_MSST_press all pressure fix-ID_MSST_temp
compute fix-ID_MSST_pe all pe
```

See the `compute temp` and `compute pressure` commands for details. Note that the IDs of the new computes are the fix-ID + “_MSST_temp” or “MSST_press” or “_MSST_pe”. The group for the new computes is “all”.

The `dftb` keyword is to allow this fix to be used when LAMMPS is being driven by DFTB+, a density-functional tight-binding code. If the keyword `dftb` is used with a value of `yes`, then the MSST equations are altered to account for the electron entropy contribution to the Hugoniot relations and total energy. See (Reed2) and (Goldman) for details on this contribution. In this case, you must define a `fix external` command in your input script, which is used to callback to DFTB+ during the LAMMPS timestepping. DFTB+ will communicate its info to LAMMPS via that fix.

18.82.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of all internal variables to binary restart files. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The progress of the MSST can be monitored by printing the global scalar and global vector quantities computed by the fix.

The scalar is the cumulative energy change due to the fix. This is also the energy added to the potential energy by the `fix_modify energy` command. With this command, the thermo keyword `etotal` prints the conserved quantity of the MSST dynamic equations. This can be used to test if the MD timestep is sufficiently small for accurate integration of the dynamic equations. See also `thermo_style` command.

The global vector contains four values in this order:

- `dhugoniot`, departure from the Hugoniot (temperature units).
- `drayleigh`, departure from the Rayleigh line (pressure units).
- `lagrangian_speed`, laboratory-frame Lagrangian speed (particle velocity) of the computational cell (velocity units).
- `lagrangian_position`, computational cell position in the reference frame moving at the shock speed. This is usually a good estimate of distance of the computational cell behind the shock front.

To print these quantities to the log file with descriptive column headers, the following LAMMPS commands are suggested:

```plaintext
fix             msst all msst z
fix_modify      msst energy yes
variable dhug   equal f_msst[1]
variable dray   equal f_msst[2]
variable lgr_vel equal f_msst[3]
variable lgr_pos equal f_msst[4]
thermo_style   custom step temp ke pe lz pzz etotal v_dhug v_dray v_lgr_vel v_lgr_pos f_msst
```

18.82. fix msst command
These fixes compute a global scalar and a global vector of 4 quantities, which can be accessed by various output commands. The scalar values calculated by this fix are “extensive”; the vector values are “intensive”.

### 18.82.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

All cell dimensions must be periodic. This fix can not be used with a triclinic cell. The MSST fix has been tested only for the group-ID all.

### 18.82.6 Related commands

`fix nphug`, `fix deform`

### 18.82.7 Default

The keyword defaults are $q = 10$, $mu = 0$, $t_{scale} = 0.01$, $dftb = no$, $beta = 0.0$. Note that $p0$, $v0$, and $e0$ are calculated on the first timestep.

### 18.83 fix mvv/dpd command

### 18.84 fix mvv/edpd command

### 18.85 fix mvv/tdpd command

#### 18.85.1 Syntax

```
fix ID group-ID mvv/dpd lambda
fix ID group-ID mvv/edpd lambda
fix ID group-ID mvv/tdpd lambda
```

- ID, group-ID are documented in `fix` command
- mvv/dpd, mvv/edpd, mvv/tdpd = style name of this fix command
- lambda = (optional) relaxation parameter (unitless)
18.85.2 Examples

```plaintext
fix 1 all mvv/dpd
fix 1 all mvv/dpd 0.5
fix 1 all mvv/edpd
fix 1 all mvv/edpd 0.5
fix 1 all mvv/tdpd
fix 1 all mvv/tdpd 0.5
```

18.85.3 Description

Perform time integration using the modified velocity-Verlet (MVV) algorithm to update position and velocity (fix mvv/dpd), or position, velocity and temperature (fix mvv/edpd), or position, velocity and concentration (fix mvv/tdpd) for particles in the group each timestep.

The modified velocity-Verlet (MVV) algorithm aims to improve the stability of the time integrator by using an extrapolated version of the velocity for the force evaluation:

\[
\begin{align*}
\frac{v(t + \Delta t)}{2} &= v(t) + \frac{\Delta t}{2} \cdot a(t) \\
r(t + \Delta t) &= r(t) + \Delta t \cdot v(t + \frac{\Delta t}{2}) \\
a(t + \Delta t) &= \frac{1}{m} \cdot F [r(t + \Delta t), v(t) + \lambda \cdot \Delta t \cdot a(t)] \\
v(t + \Delta t) &= v(t + \frac{\Delta t}{2}) + \frac{\Delta t}{2} \cdot a(t + \Delta t)
\end{align*}
\]

where the parameter \(\lambda\) depends on the specific choice of DPD parameters, and needs to be tuned on a case-by-case basis. Specification of a \(\lambda\) value is optional. If specified, the setting must be from 0.0 to 1.0. If not specified, a default value of 0.5 is used, which effectively reproduces the standard velocity-Verlet (VV) scheme. For more details, see Groot.

Fix `mvv/dpd` updates the position and velocity of each atom. It can be used with the `pair_style mdpd` command or other pair styles such as `pair dpd`.

Fix `mvv/edpd` updates the per-atom temperature, in addition to position and velocity, and must be used with the `pair_style edpd` command.

Fix `mvv/tdpd` updates the per-atom chemical concentration, in addition to position and velocity, and must be used with the `pair_style tdpd` command.

18.85.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.
18.85.5 Restrictions

This fix is part of the USER-MESODPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.85.6 Related commands

pair_style mdpd, pair_style edpd, pair_style tdpd

fix 2 all neb 1.0 perp 1.0 end last
fix 2 all neb 1.0 perp 1.0 end first 1.0 end last 1.0
fix 1 all neb 1.0 parallel ideal end last/efirst 1
```

18.86.3 Description

Add nudging forces to atoms in the group for a multi-replica simulation run via the `nub` command to perform a nudged elastic band (NEB) calculation for finding the transition state. Hi-level explanations of NEB are given with the `nub` command and on the Howto replica doc page. The fix neb command must be used with the “nub” command and defines how inter-replica nudging forces are computed. A NEB calculation is divided in two stages. In the first stage n replicas are relaxed toward a MEP until convergence. In the second stage, the climbing image scheme (see (Henkelman2)) is enabled, so that the replica having the highest energy relaxes toward the saddle point (i.e. the point of highest energy along the MEP), and a second relaxation is performed.

A key purpose of the nudging forces is to keep the replicas equally spaced. During the NEB calculation, the 3N-length vector of interatomic force \( \mathbf{F}_i = -\nabla V \) for each replica \( i \) is altered. For all intermediate replicas (i.e. for \( 1 < i < N \), except the climbing replica) the force vector becomes:

\[
\mathbf{F}_i = -\nabla V + (\nabla V \cdot \mathbf{T}') \mathbf{T}' + \mathbf{F}_{\text{nudge parallel}} + \mathbf{F}_{\text{nudge perp}}
\]

\( \mathbf{T}' \) is the unit “tangent” vector for replica \( i \) and is a function of \( R_i, R_i-1, R_i+1 \), and the potential energy of the 3 replicas; it points roughly in the direction of \( (R_{i+1} - R_i) \); see the (Henkelman1) paper for details. \( R_i \) are the atomic coordinates of replica \( i \); \( R_i-1 \) and \( R_i+1 \) are the coordinates of its neighbor replicas. The term \( (\nabla V \cdot \mathbf{T}') \) is used to remove the component of the gradient parallel to the path which would tend to distribute the replica unevenly along the path. \( \mathbf{F}_{\text{nudge parallel}} \) is an artificial nudging force which is applied only in the tangent direction and which maintains the equal spacing between replicas (see below for more information). \( \mathbf{F}_{\text{nudge perp}} \) is an optional artificial spring which is applied in a direction perpendicular to the tangent direction and which prevent the paths from forming acute kinks (see below for more information).

In the second stage of the NEB calculation, the interatomic force \( \mathbf{F}_i \) for the climbing replica (the replica of highest energy after the first stage) is changed to:

\[
\mathbf{F}_i = -\nabla V + 2 (\nabla V \cdot \mathbf{T}') \mathbf{T}'
\]

and the relaxation procedure is continued to a new converged MEP.

The keyword `parallel` specifies how the parallel nudging force is computed. With a value of `neigh`, the parallel nudging force is computed as in (Henkelman1) by connecting each intermediate replica with the previous and the next image:

\[
\mathbf{F}_{\text{nudge parallel}} = K_{Spring} \times (|R_{i+1} - R_i| - |R_i - R_{i-1}|)
\]

Note that in this case the specified \( K_{Spring} \) is in force/distance units.

With a value of `ideal`, the spring force is computed as suggested in ref (WeinanE) <WeinanE>:

\[
\mathbf{F}_{\text{nudge parallel}} = -K_{Spring} \times (R_D - R_{D\text{ideal}}) / (2 \times \text{meanDist})
\]

where \( R_D \) is the “reaction coordinate” see `nub` section, and \( R_{D\text{ideal}} \) is the ideal \( R_D \) for which all the images are equally spaced. I.e. \( R_{D\text{ideal}} = (I-1)\times \text{meanDist} \) when the climbing replica is off, where \( I \) is the replica number). The meanDist is the average distance between replicas. Note that in this case the specified \( K_{Spring} \) is in force units.

Note that the `ideal` form of nudging can often be more effective at keeping the replicas equally spaced.
The keyword *perp* specifies if and how a perpendicular nudging force is computed. It adds a spring force perpendicular to the path in order to prevent the path from becoming too strongly kinked. It can significantly improve the convergence of the NEB calculation when the resolution is poor. I.e. when few replicas are used; see *(Maras)* for details.

The perpendicular spring force is given by

\[ F_{\text{nudge\_perp}} = K_{\text{spring2}} \cdot F(R_{i-1}, R_i, R_{i+1}) \cdot (R_{i+1} + R_{i-1} - 2 \cdot R_i) \]

where \( K_{\text{spring2}} \) is the specified value. \( F(R_{i-1}, R_i, R_{i+1}) \) is a smooth scalar function of the angle \( R_{i-1} R_i R_{i+1} \). It is equal to 0.0 when the path is straight and is equal to 1 when the angle \( R_{i-1} R_i R_{i+1} \) is acute. \( F(R_{i-1}, R_i, R_{i+1}) \) is defined in *(Jonsson)*.

If \( K_{\text{spring2}} \) is set to 0.0 (the default) then no perpendicular spring force is added.

By default, no additional forces act on the first and last replicas during the NEB relaxation, so these replicas simply relax toward their respective local minima. By using the key word *end*, additional forces can be applied to the first and/or last replicas, to enable them to relax toward a MEP while constraining their energy \( E \) to the target energy \( E_{\text{Target}} \).

If \( E_{\text{Target}} \geq E \), the interatomic force \( F_i \) for the specified replica becomes:

\[
F_i = -\nabla E(V) + (\nabla E(V) \cdot T' + (E - E_{\text{Target}}) \cdot K_{\text{spring3}}) T', \quad \text{when } \nabla E(V) \cdot T' < 0 \\
F_i = -\nabla E(V) + (\nabla E(V) \cdot T' + (E_{\text{Target}} - E) \cdot K_{\text{spring3}}) T', \quad \text{when } \nabla E(V) \cdot T' > 0
\]

The “spring” constant on the difference in energies is the specified \( K_{\text{spring3}} \) value.

When *estyle* is specified as *first*, the force is applied to the first replica. When *estyle* is specified as *last*, the force is applied to the last replica. Note that the *end* keyword can be used twice to add forces to both the first and last replicas.

For both these *estyle* settings, the target energy \( E_{\text{Target}} \) is set to the initial energy of the replica (at the start of the NEB calculation).

If the *estyle* is specified as *last/efirst* or *last/efirst/middle*, force is applied to the last replica, but the target energy \( E_{\text{Target}} \) is continuously set to the energy of the first replica, as it evolves during the NEB relaxation.

The difference between these two *estyle* options is as follows. When *estyle* is specified as *last/efirst*, no change is made to the inter-replica force applied to the intermediate replicas (neither first or last). If the initial path is too far from the MEP, an intermediate replica may relax “faster” and reach a lower energy than the last replica. In this case the intermediate replica will be relaxing toward its own local minima. This behavior can be prevented by specifying *estyle* as *last/efirst/middle* which will alter the inter-replica force applied to intermediate replicas by removing the contribution of the gradient to the inter-replica force. This will only be done if a particular intermediate replica has a lower energy than the first replica. This should effectively prevent the intermediate replicas from over-relaxing.

After converging a NEB calculation using an *estyle* of *last/efirst/middle*, you should check that all intermediate replicas have a larger energy than the first replica. If this is not the case, the path is probably not a MEP.

Finally, note that the last replica may never reach the target energy if it is stuck in a local minima which has a larger energy than the target energy.
18.86.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, as invoked by the minimize command via the neb command.

18.86.5 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

18.87.1 Syntax

fix ID group-ID neb/spin Kspring

- ID, group-ID are documented in fix command
- neb/spin = style name of this fix command

Kspring = spring constant for parallel nudging force
(force/distance units or force units, see parallel keyword)
18.87.2 Examples

fix 1 active neb/spin 1.0

18.87.3 Description

Add nudging forces to spins in the group for a multi-replica simulation run via the `neb/spin` command to perform a geodesic nudged elastic band (GNEB) calculation for finding the transition state. Hi-level explanations of GNEB are given with the `neb/spin` command and on the `Howto replica` doc page. The fix `neb/spin` command must be used with the “neb/spin” command and defines how inter-replica nudging forces are computed. A GNEB calculation is divided in two stages. In the first stage n replicas are relaxed toward a MEP until convergence. In the second stage, the climbing image scheme is enabled, so that the replica having the highest energy relaxes toward the saddle point (i.e. the point of highest energy along the MEP), and a second relaxation is performed.

The nudging forces are calculated as explained in (BessarabB)). See this reference for more explanation about their expression.

18.87.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, as invoked by the minimize command via the `neb/spin` command.

18.87.5 Restrictions

18.90.3 Description

These commands perform time integration on Nose-Hoover style non-Hamiltonian equations of motion which are designed to generate positions and velocities sampled from the canonical (nvt), isothermal-isobaric (npt), and isenthalpic (nph) ensembles. This updates the position and velocity for atoms in the group each timestep.

The thermostatting and barostatting is achieved by adding some dynamic variables which are coupled to the particle velocities (thermostatting) and simulation domain dimensions (barostatting). In addition to basic thermostatting and barostatting, these fixes can also create a chain of thermostats coupled to the particle thermostat, and another chain of thermostats coupled to the barostat variables. The barostat can be coupled to the overall box volume, or to individual dimensions, including the $xy$, $xz$ and $yz$ tilt dimensions. The external pressure of the barostat can be specified as either a scalar pressure (isobaric ensemble) or as components of a symmetric stress tensor (constant stress ensemble). When used correctly, the time-averaged temperature and stress tensor of the particles will match the target values specified by $T_{start}/T_{stop}$ and $P_{start}/P_{stop}$.

The equations of motion used are those of Shinoda et al in (Shinoda), which combine the hydrostatic equations of Martyna, Tobias and Klein in (Martyna) with the strain energy proposed by Parrinello and Rahman in (Parrinello). The time integration schemes closely follow the time-reversible measure-preserving Verlet and rRESPA integrators derived by Tuckerman et al in (Tuckerman).

The thermostat parameters for fix styles nvt and npt are specified using the temp keyword. Other thermostat-related keywords are tchain, tloop and drag, which are discussed below.

The thermostat is applied to only the translational degrees of freedom for the particles. The translational degrees of freedom can also have a bias velocity removed before thermostatting takes place; see the description below. The desired temperature at each timestep is a ramped value during the run from $T_{start}$ to $T_{stop}$. The $Tdamp$ parameter is
specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 10.0 means to relax the temperature in a timespan of (roughly) 10 time units (e.g. \( \tau \) or fs or ps - see the \textit{units} command). The atoms in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the integration.

\textbf{Note:} A Nose-Hoover thermostat will not work well for arbitrary values of \textit{Tdamp}. If \textit{Tdamp} is too small, the temperature can fluctuate wildly; if it is too large, the temperature will take a very long time to equilibrate. A good choice for many models is a \textit{Tdamp} of around 100 timesteps. Note that this is NOT the same as 100 time units for most \textit{units} settings. A simple way to ensure this, is via using an \textit{immediate variable} expression accessing the thermo property '\textit{dt}', which is the length of the time step. Example:

\begin{verbatim}
fix 1 all nvt temp 300.0 300.0 $(100.0*dt)
\end{verbatim}

The barostat parameters for fix styles \textit{npt} and \textit{nph} is specified using one or more of the \textit{iso}, \textit{aniso}, \textit{tri}, \textit{x}, \textit{y}, \textit{z}, \textit{xy}, \textit{xz}, \textit{yz}, and \textit{couple} keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation.

Other barostat-related keywords are \textit{pchain}, \textit{mtk}, \textit{ploop}, \textit{nreset}, \textit{drag}, and \textit{dilate}, which are discussed below.

Orthogonal simulation boxes have 3 adjustable dimensions (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable dimensions (x,y,z,xy,xz,yz). The \textit{create_box}, \textit{read data}, and \textit{read_restart} commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

The target pressures for each of the 6 components of the stress tensor can be specified independently via the \textit{x}, \textit{y}, \textit{z}, \textit{xy}, \textit{xz}, \textit{yz} keywords, which correspond to the 6 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from \textit{Pstart} to \textit{Pstop}. If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the \textit{y} keyword is used, the y-box length will change. If the \textit{xy} keyword is used, the xy tilt factor will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the \textit{fix deform} command.

Note that in order to use the \textit{xy}, \textit{xz}, or \textit{yz} keywords, the simulation box must be triclinic, even if its initial tilt factors are 0.0.

For all barostat keywords, the \textit{Pdamp} parameter operates like the \textit{Tdamp} parameter, determining the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (e.g. \( \tau \) or fs or ps - see the \textit{units} command).

\textbf{Note:} A Nose-Hoover barostat will not work well for arbitrary values of \textit{Pdamp}. If \textit{Pdamp} is too small, the pressure and volume can fluctuate wildly; if it is too large, the pressure will take a very long time to equilibrate. A good choice for many models is a \textit{Pdamp} of around 1000 timesteps. However, note that \textit{Pdamp} is specified in time units, and that timesteps are NOT the same as time units for most \textit{units} settings.

The relaxation rate of the barostat is set by its inertia \( W \):

\[ W = (N + 1)kT_{\text{target}}P_{\text{damp}}^2 \]

where \( N \) is the number of atoms, \( k \) is the Boltzmann constant, and \( T_{\text{target}} \) is the target temperature of the barostat \textit{(Martyna)}. If a thermostat is defined, \( T_{\text{target}} \) is the target temperature of the thermostat. If a thermostat is not defined, \( T_{\text{target}} \) is set to the current temperature of the system when the barostat is initialized. If this temperature is too low the simulation will quit with an error. Note: in previous versions of LAMMPS, \( T_{\text{target}} \) would default to a value of 1.0 for \textit{lj} units and 300.0 otherwise if the system had a temperature of exactly zero.

18.90. \textit{fix nph} command 1197
If a thermostat is not specified by this fix, $T_{\text{target}}$ can be manually specified using the $P_{\text{temp}}$ parameter. This may be useful if the barostat is initialized when the current temperature does not reflect the steady state temperature of the system. This keyword may also be useful in athermal simulations where the temperature is not well defined.

Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword dilate is specified with a dilate-group-ID for a group that represents a subset of the atoms. This can be useful, for example, to leave the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid. This option should be used with care, since it can be unphysical to dilate some atoms and not others, because it can introduce large, instantaneous displacements between a pair of atoms (one dilated, one not) that are far from the dilation origin. Also note that for atoms not in the fix group, a separate time integration fix like fix nve or fix nvt can be used on them, independent of whether they are dilated or not.

The `couple` keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, $xz$ means the $P_{xx}$ and $P_{zz}$ components of the stress tensor are coupled. $Xyz$ means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The $P_{\text{start}}$, $P_{\text{stop}}$, $P_{\text{damp}}$ parameters for any coupled dimensions must be identical. *Couple xz* can be used for a 2d simulation; the $z$ dimension is simply ignored.

The `iso`, `aniso`, and `tri` keywords are simply shortcuts that are equivalent to specifying several other keywords together. The keyword `iso` means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “iso $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$” is the same as specifying these 4 keywords:

```
x $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$
y $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$
z $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$
couple xyz
```

The keyword `aniso` means $x$, $y$, and $z$ dimensions are controlled independently using the $P_{xx}$, $P_{yy}$, and $P_{zz}$ components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “aniso $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$” is the same as specifying these 4 keywords:

```
x $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$
y $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$
z $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$
couple none
```

The keyword `tri` means $x$, $y$, $z$, $xy$, $xz$, and $yz$ dimensions are controlled independently using their individual stress components as the driving forces, and the specified scalar pressure as the external normal stress. Using “tri $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$” is the same as specifying these 7 keywords:

```
x $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$
y $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$
z $P_{\text{start}}$ $P_{\text{stop}}$ $P_{\text{damp}}$
xy 0.0 0.0 $P_{\text{damp}}$
xyz 0.0 0.0 $P_{\text{damp}}$
```

```
```
In some cases (e.g. for solids) the pressure (volume) and/or temperature of the system can oscillate undesirably when a Nose/Hoover barostat and thermostat is applied. The optional drag keyword will damp these oscillations, although it alters the Nose/Hoover equations. A value of 0.0 (no drag) leaves the Nose/Hoover formalism unchanged. A non-zero value adds a drag term; the larger the value specified, the greater the damping effect. Performing a short run and monitoring the pressure and temperature is the best way to determine if the drag term is working. Typically a value between 0.2 to 2.0 is sufficient to damp oscillations after a few periods. Note that use of the drag keyword will interfere with energy conservation and will also change the distribution of positions and velocities so that they do not correspond to the nominal NVT, NPT, or NPH ensembles.

An alternative way to control initial oscillations is to use chain thermostats. The keyword tchain determines the number of thermostats in the particle thermostat. A value of 1 corresponds to the original Nose-Hoover thermostat. The keyword pchain specifies the number of thermostats in the chain thermostatting the barostat degrees of freedom. A value of 0 corresponds to no thermostatting of the barostat variables.

The mtk keyword controls whether or not the correction terms due to Martyna, Tuckerman, and Klein are included in the equations of motion (Martyna). Specifying no reproduces the original Hoover barostat, whose volume probability distribution function differs from the true NPT and NPH ensembles by a factor of 1/V. Hence using yes is more correct, but in many cases the difference is negligible.

The keyword tloop can be used to improve the accuracy of integration scheme at little extra cost. The initial and final updates of the thermostat variables are broken up into tloop sub-steps, each of length dt/tloop. This corresponds to using a first-order Suzuki-Yoshida scheme (Tuckerman). The keyword ploop does the same thing for the barostat thermostat.

The keyword nreset controls how often the reference dimensions used to define the strain energy are reset. If this keyword is not used, or is given a value of zero, then the reference dimensions are set to those of the initial simulation domain and are never changed. If the simulation domain changes significantly during the simulation, then the final average pressure tensor will differ significantly from the specified values of the external stress tensor. A value of nstep means that every nstep timesteps, the reference dimensions are set to those of the current simulation domain.

The scalexz, scaleyz, and scalexy keywords control whether or not the corresponding tilt factors are scaled with the associated box dimensions when barostatting triclinic periodic cells. The default values yes will turn on scaling, which corresponds to adjusting the linear dimensions of the cell while preserving its shape. Choosing no ensures that the tilt factors are not scaled with the box dimensions. See below for restrictions and default values in different situations. In older versions of LAMMPS, scaling of tilt factors was not performed. The old behavior can be recovered by setting all three scale keywords to no.

The flip keyword allows the tilt factors for a triclinic box to exceed half the distance of the parallel box length, as discussed below. If the flip value is set to yes, the bound is enforced by flipping the box when it is exceeded. If the flip value is set to no, the tilt will continue to change without flipping. Note that if applied stress induces large deformations (e.g. in a liquid), this means the box shape can tilt dramatically and LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor’s irregular-shaped sub-domain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

The fixedpoint keyword specifies the fixed point for barostat volume changes. By default, it is the center of the box. Whatever point is chosen will not move during the simulation. For example, if the lower periodic boundaries pass through (0,0,0), and this point is provided to fixedpoint, then the lower periodic boundaries will remain at (0,0,0), while the upper periodic boundaries will move twice as far. In all cases, the particle trajectories are unaffected by the chosen value, except for a time-dependent constant translation of positions.

If the update keyword is used with the dipole value, then the orientation of the dipole moment of each particle is also updated during the time integration. This option should be used for models where a dipole moment is assigned to finite-size particles, e.g. spheroids via use of the atom_style hybrid sphere dipole command.

The default dipole orientation integrator can be changed to the Dullweber-Leimkuhler-McLachlan integration scheme (Dullweber) when using update with the value dipole/dlm. This integrator is symplectic and time-reversible, giving better energy conservation and allows slightly longer timesteps at only a small additional computational cost.
Note: Using a barostat coupled to tilt dimensions $xy$, $xz$, $yz$ can sometimes result in arbitrarily large values of the tilt dimensions, i.e. a dramatically deformed simulation box. LAMMPS allows the tilt factors to grow a small amount beyond the normal limit of half the box length (0.6 times the box length), and then performs a box “flip” to an equivalent periodic cell. See the discussion of the flip keyword above, to allow this bound to be exceeded, if desired.

The flip operation is described in more detail in the doc page for fix deform. Both the barostat dynamics and the atom trajectories are unaffected by this operation. However, if a tilt factor is incremented by a large amount (1.5 times the box length) on a single timestep, LAMMPS can not accommodate this event and will terminate the simulation with an error. This error typically indicates that there is something badly wrong with how the simulation was constructed, such as specifying values of $P_{start}$ that are too far from the current stress value, or specifying a timestep that is too large. Triclinic barostatting should be used with care. This also is true for other barostat styles, although they tend to be more forgiving of insults. In particular, it is important to recognize that equilibrium liquids can not support a shear stress and that equilibrium solids can not support shear stresses that exceed the yield stress.

One exception to this rule is if the first dimension in the tilt factor (x for $xy$) is non-periodic. In that case, the limits on the tilt factor are not enforced, since flipping the box in that dimension does not change the atom positions due to non-periodicity. In this mode, if you tilt the system to extreme angles, the simulation will simply become inefficient due to the highly skewed simulation box.

Note: Unlike the fix temp/berendsen command which performs thermostatting but NO time integration, these fixes perform thermostatting/barostatting AND time integration. Thus you should not use any other time integration fix, such as fix nve on atoms to which this fix is applied. Likewise, fix nvt and fix npt should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by fix langevin or fix temp/rescale commands.

See the Howto thermostat and Howto barostat doc pages for a discussion of different ways to compute temperature and perform thermostatting and barostatting.

These fixes compute a temperature and pressure each timestep. To do this, the thermostat and barostat fixes create their own computes of style “temp” and “pressure”, as if one of these sets of commands had been issued:

For fix nvt:

```
compute fix-ID_temp group-ID temp
```

For fix npt and fix nph:

```
compute fix-ID_temp all temp
compute fix-ID_press all pressure fix-ID_temp
```

For fix nvt, the group for the new temperature compute is the same as the fix group. For fix npt and fix nph, the group for both the new temperature and pressure compute is “all” since pressure is computed for the entire system. In the case of fix nph, the temperature compute is not used for thermostatting, but just for a kinetic-energy contribution to the pressure. See the compute temp and compute pressure commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”.

Note that these are NOT the computes used by thermodynamic output (see the thermo_style command) with ID = thermo_temp and thermo_press. This means you can change the attributes of these fix’s temperature or pressure via the compute_modify command. Or you can print this temperature or pressure during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp or thermo_press will have no effect on this fix.
Like other fixes that perform thermostatting, fix nvt and fix npt can be used with compute commands that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the fix modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute commands to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

These fixes can be used with either the verlet or respa integrators. When using one of the barostat fixes with respa, LAMMPS uses an integrator constructed according to the following factorization of the Liouville propagator (for two rRESPA levels):

\[
\exp(iL\Delta t) = \hat{E} \exp\left(iL_{\text{baro}} \frac{\Delta t}{2}\right) \exp\left(iL_{\text{part}} \frac{\Delta t}{2}\right) \exp\left(iL_{\epsilon,2} \frac{\Delta t}{2}\right) \exp\left(iL_{\text{baro}}^{(2)} \frac{\Delta t}{2}\right) \\
\times \left[ \exp\left(iL_{1}^{(1)} \frac{\Delta t}{2n}\right) \exp\left(iL_{\epsilon,1} \frac{\Delta t}{2n}\right) \exp\left(iL_{1} \frac{\Delta t}{n}\right) \exp\left(iL_{\epsilon,1} \frac{\Delta t}{2n}\right) \exp\left(iL_{1}^{(1)} \frac{\Delta t}{2n}\right) \right]^{n} \\
\times \exp\left(iL_{2}^{(2)} \frac{\Delta t}{2}\right) \exp\left(iL_{\epsilon,2} \frac{\Delta t}{2}\right) \exp\left(iL_{\text{part}} \frac{\Delta t}{2}\right) \exp\left(iL_{\text{baro}} \frac{\Delta t}{2}\right) \\
+ \mathcal{O}(\Delta t^{3})
\]

This factorization differs somewhat from that of Tuckerman et al, in that the barostat is only updated at the outermost rRESPA level, whereas Tuckerman’s factorization requires splitting the pressure into pieces corresponding to the forces computed at each rRESPA level. In theory, the latter method will exhibit better numerical stability. In practice, because Pdamp is normally chosen to be a large multiple of the outermost rRESPA timestep, the barostat dynamics are not the limiting factor for numerical stability. Both factorizations are time-reversible and can be shown to preserve the phase space measure of the underlying non-Hamiltonian equations of motion.

**Note:** This implementation has been shown to conserve linear momentum up to machine precision under NVT dynamics. Under NPT dynamics, for a system with zero initial total linear momentum, the total momentum fluctuates close to zero. It may occasionally undergo brief excursions to non-negligible values, before returning close to zero. Over long simulations, this has the effect of causing the center-of-mass to undergo a slow random walk. This can be mitigated by resetting the momentum at infrequent intervals using the fix momentum command.

The fix npt and fix nph commands can be used with rigid bodies or mixtures of rigid bodies and non-rigid particles (e.g. solvent). But there are also fix rigid/npt and fix rigid/nph commands, which are typically a more natural choice. See the doc page for those commands for more discussion of the various ways to do this.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
18.90.4 Restart, fix_modify, output, run start/stop, minimize info

These fixes writes the state of all the thermostat and barostat variables to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by these fixes. You can use them to assign a compute you have defined to this fix which will be used in its thermostating or barostatting procedure, as described above. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

Note: If both the temp and press keywords are used in a single thermo_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a pressure compute defines its own temperature compute as an argument when it is specified. The temp keyword will override this (for the pressure compute being used by fix npt), but only if the temp keyword comes after the press keyword. If the temp keyword comes before the press keyword, then the new pressure compute specified by the press keyword will be unaffected by the temp setting.

The fix_modify energy option is supported by these fixes to add the energy change induced by Nose/Hoover thermostating and barostatting to the system’s potential energy as part of thermodynamic output.

These fixes compute a global scalar and a global vector of quantities, which can be accessed by various output commands. The scalar value calculated by these fixes is “extensive”; the vector values are “intensive”.

The scalar is the cumulative energy change due to the fix.

The vector stores internal Nose/Hoover thermostat and barostat variables. The number and meaning of the vector values depends on which fix is used and the settings for keywords tchain and pchain, which specify the number of Nose/Hoover chains for the thermostat and barostat. If no thermostating is done, then tchain is 0. If no barostatting is done, then pchain is 0. In the following list, “ndof” is 0, 1, 3, or 6, and is the number of degrees of freedom in the barostat. Its value is 0 if no barostat is used, else its value is 6 if any off-diagonal stress tensor component is barostatted, else its value is 1 if couple xyz is used or couple xy for a 2d simulation, otherwise its value is 3.

The order of values in the global vector and their meaning is as follows. The notation means there are tchain values for eta, followed by tchain for eta_dot, followed by ndof for omega, etc:

• eta[tchain] = particle thermostat displacements (unitless)
• eta_dot[tchain] = particle thermostat velocities (1/time units)
• omega[ndof] = barostat displacements (unitless)
• omega_dot[ndof] = barostat velocities (1/time units)
• etap[pchain] = barostat thermostat displacements (unitless)
• etap_dot[pchain] = barostat thermostat velocities (1/time units)
• PE_ eta[tchain] = potential energy of each particle thermostat displacement (energy units)
• KE_ eta_dot[tchain] = kinetic energy of each particle thermostat velocity (energy units)
• PE_omega[ndof] = potential energy of each barostat displacement (energy units)
• KE_omega_dot[ndof] = kinetic energy of each barostat velocity (energy units)
• PE_etap[pchain] = potential energy of each barostat thermostat displacement (energy units)
• KE_etap_dot[pchain] = kinetic energy of each barostat thermostat velocity (energy units)
• PE_strain[1] = scalar strain energy (energy units)
These fixes can ramp their external temperature and pressure over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

These fixes are not invoked during `energy minimization`.

### 18.90.5 Restrictions

X, y, z cannot be barostatted if the associated dimension is not periodic. Xy, xz, and yz can only be barostatted if the simulation domain is triclinic and the second dimension in the keyword (y dimension in xy) is periodic. Z, xz, and yz, cannot be barostatted for 2D simulations. The `create_box`, `read data`, and `read_restart` commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

For the `temp` keyword, the final Tstop cannot be 0.0 since it would make the external T = 0.0 at some timestep during the simulation which is not allowed in the Nose/Hoover formulation.

The `scaleyz yes` and `scalexz yes` keyword/value pairs can not be used for 2D simulations. `scaleyz yes`, `scalexz yes`, and `scalexy yes` options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords `tri`, `yz`, `xz`, and `xy`.

These fixes can be used with dynamic groups as defined by the `group` command. Likewise they can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

### 18.90.6 Related commands

`fix nve`, `fix_modify`, `run_style`

### 18.90.7 Default

The keyword defaults are `tchain = 3`, `pchain = 3`, `mtk = yes`, `tloop = 1`, `ploop = 1`, `nreset = 0`, `drag = 0.0`, `dilate = all`, `couple = none`, `flip = yes`, `scaleyz = scalexz = scalexy = yes` if periodic in second dimension and not coupled to barostat, otherwise no.

18.91 fix nvt/eff command

18.92 fix npt/eff command

18.93 fix nph/eff command

18.93.1 Syntax

```
fix ID group-ID style_name keyword value ...
```

- ID, group-ID are documented in `fix` command
- `style_name` = `nvt/eff` or `npt/eff` or `nph/eff`

one or more keyword value pairs may be appended

- `temp` or `iso` or `aniso` or `tri` or `x` or `y` or `z` or `xy` or `yz` or `xz` or `couple` or `tchain` or `pchain` or `mtk` or `tloop` or `ploop` or `nreset` or `drag` or `dilate`

- `temp` values = `Tstart` `Tstop` `Tdamp`
  
  - `Tstart`, `Tstop` = external temperature at start/end of run
  - `Tdamp` = temperature damping parameter (time units)

- `iso` or `aniso` or `tri` values = `Pstart` `Pstop` `Pdamp`

  - `Pstart`, `Pstop` = scalar external pressure at start/end of run (pressure units)
  - `Pdamp` = pressure damping parameter (time units)

- `x` or `y` or `z` or `xy` or `yz` or `xz` values = `Pstart` `Pstop` `Pdamp`

  - `Pstart`, `Pstop` = external stress tensor component at start/end of run (pressure units)
  - `Pdamp` = stress damping parameter (time units)

- `couple` = `none` or `xyz` or `xy` or `yz` or `xz`

- `tchain` value = length of thermostat chain (1 = single thermostat)

- `pchain` values = length of thermostat chain on barostat (0 = no thermostat)

- `mtk` value = `yes` or `no` = add in MTK adjustment term or not

- `tloop` value = number of sub-cycles to perform on thermostat

- `ploop` value = number of sub-cycles to perform on barostat thermostat

- `nreset` value = reset reference cell every this many timesteps

- `drag` value = drag factor added to barostat/thermostat (0.0 = no drag)

- `dilate` value = `all` or `partial`

18.93.2 Examples

```
fix 1 all nvt/eff temp 300.0 300.0 0.1
fix 1 part npt/eff temp 300.0 300.0 0.1 iso 0.0 0.0 1.0
fix 2 part npt/eff temp 300.0 300.0 0.1 tri 5.0 5.0 1.0
fix 2 ice nph/eff x 1.0 1.0 0.5 y 2.0 2.0 0.5 z 3.0 3.0 0.5 yz 0.1 0.1 0.5 xz 0.2 0.2
   0.5 xy 0.3 0.3 0.5 nreset 1000
```
18.93.3 Description

These commands perform time integration on Nose-Hoover style non-Hamiltonian equations of motion for nuclei and electrons in the group for the electron force field model. The fixes are designed to generate positions and velocities sampled from the canonical (nvt), isothermal-isobaric (npt), and isenthalpic (nph) ensembles. This is achieved by adding some dynamic variables which are coupled to the particle velocities (thermostatting) and simulation domain dimensions (barostatting). In addition to basic thermostatting and barostatting, these fixes can also create a chain of thermostats coupled to the particle thermostat, and another chain of thermostats coupled to the barostat variables. The barostat can be coupled to the overall box volume, or to individual dimensions, including the xy, xz and yz tilt dimensions. The external pressure of the barostat can be specified as either a scalar pressure (isobaric ensemble) or as components of a symmetric stress tensor (constant stress ensemble). When used correctly, the time-averaged temperature and stress tensor of the particles will match the target values specified by Tstart/Tstop and Pstart/Pstop.

The operation of these fixes is exactly like that described by the fix nvt, npt, and nph commands, except that the radius and radial velocity of electrons are also updated. Likewise the temperature and pressure calculated by the fix, using the computes it creates (as discussed in the fix nvt, npt, and nph doc page), are performed with computes that include the eFF contribution to the temperature or kinetic energy from the electron radial velocity.

Note: there are two different pressures that can be reported for eFF when defining the pair_style (see pair eff/cut to understand these settings), one (default) that considers electrons do not contribute radial virial components (i.e. electrons treated as incompressible ‘rigid’ spheres) and one that does. The radial electronic contributions to the virials are only tallied if the flexible pressure option is set, and this will affect both global and per-atom quantities. In principle, the true pressure of a system is somewhere in between the rigid and the flexible eFF pressures, but, for most cases, the difference between these two pressures will not be significant over long-term averaged runs (i.e. even though the energy partitioning changes, the total energy remains similar).

Note: currently, there is no available option for the user to set or create temperature distributions that include the radial electronic degrees of freedom with the velocity command, so the the user must allow for these degrees of freedom to equilibrate (i.e. equi-partitioning of energy) through time integration.

18.93.4 Restart, fix_modify, output, run start/stop, minimize info

See the doc page for the fix nvt, npt, and nph commands for details.

18.93.5 Restrictions

This fix is part of the USER-EFF package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Other restriction discussed on the doc page for the fix nvt, npt, and nph commands also apply.

Note: The temperature for systems (regions or groups) with only electrons and no nuclei is 0.0 (i.e. not defined) in the current temperature calculations, a practical example would be a uniform electron gas or a very hot plasma, where electrons remain delocalized from the nuclei. This is because, even though electron virials are included in the temperature calculation, these are averaged over the nuclear degrees of freedom only. In such cases a corrective term must be added to the pressure to get the correct kinetic contribution.
18.93.6 Related commands

fix nvt, fix nph, fix npt, fix_modify, run_style

18.93.7 Default

The keyword defaults are tchain = 3, pchain = 3, mtk = yes, tloop = ploop = 1, nreset = 0, drag = 0.0, dilate = all, and couple = none.

18.94 fix nvt/uef command

18.95 fix npt/uef command

18.95.1 Syntax

```
fix ID group-ID style_name edot_x edot_y temp Tstart Tstop Tdamp keyword value .
```

- ID, group-ID are documented in `fix` command
- style_name = nvt/uef or npt/uef
- Tstart, Tstop, and Tdamp are documented in the `fix npt` command
- edot_x and edot_y are the strain rates in the x and y directions (1/(time units))
- one or more keyword/value pairs may be appended

```
keyword = ext or strain or iso or x or y or z or tchain or pchain or tloop or ploop or mtk

ext value = x or y or z or xy or yz or xz = external dimensions
strain values = e_x e_y = initial strain
usually not needed, but may be needed to resume a run with a data file.
iso, x, y, z, tchain, pchain, tloop, ploop, mtk keywords documented by the `fix npt` command
```
18.95.2 Examples

```

fix biax_nvt all nvt/uef temp 400 400 100 erate 0.000005 0.000005
fix uniax_npt all npt/uef temp 400 400 300 iso 1 1 3000 erate 0.00001 -0.000005 ext yz
fix biax_npt all npt/uef temp 400 400 100 erate -0.00001 0.000005 x 1 1 3000
```

18.95.3 Description

This fix can be used to simulate non-equilibrium molecular dynamics (NEMD) under diagonal flow fields, including uniaxial and bi-axial flow. Simulations under continuous extensional flow may be carried out for an indefinite amount of time. It is an implementation of the boundary conditions from (Dobson), and also uses numerical lattice reduction as was proposed by (Hunt). The lattice reduction algorithm is from (Semaev). The fix is intended for simulations of homogeneous flows, and integrates the SLLOD equations of motion, originally proposed by Hoover and Ladd (see (Evans and Morriss)). Additional detail about this implementation can be found in (Nicholson and Rutledge).

Note that NEMD simulations of a continuously strained system can be performed using the fix deform, fix nvt/sllod, and compute temp/deform commands.

The applied flow field is set by the `eps` keyword. The values `edot_x` and `edot_y` correspond to the strain rates in the xx and yy directions. It is implicitly assumed that the flow field is traceless, and therefore the strain rate in the zz direction is equal to `-edot_x + edot_y`.

**Note:** Due to an instability in the SLLOD equations under extension, fix momentum should be used to regularly reset the linear momentum.

The boundary conditions require a simulation box that does not have a consistent alignment relative to the applied flow field. Since LAMMPS utilizes an upper-triangular simulation box, it is not possible to express the evolving simulation box in the same coordinate system as the flow field. This fix keeps track of two coordinate systems: the flow frame, and the upper triangular LAMMPS frame. The coordinate systems are related to each other through the QR decomposition, as is illustrated in the image below.
During most molecular dynamics operations, the system is represented in the LAMMPS frame. Only when the positions and velocities are updated is the system rotated to the flow frame, and it is rotated back to the LAMMPS frame immediately afterwards. For this reason, all vector-valued quantities (except for the tensors from `compute pressure/uef` and `compute temp/uef`) will be computed in the LAMMPS frame. Rotationally invariant scalar quantities like the temperature and hydrostatic pressure are frame-invariant and will be computed correctly. Additionally, the system is in the LAMMPS frame during all of the output steps, and therefore trajectory files made using the dump command will be in the LAMMPS frame unless the `dump cfg/uef` command is used.

Temperature control is achieved with the default Nose-Hoover style thermostat documented in `fix npt`. When this fix is active, only the peculiar velocity of each atom is stored, defined as the velocity relative to the streaming velocity. This is in contrast to `fix nvt/sllod`, which uses a lab-frame velocity, and removes the contribution from the streaming velocity in order to compute the temperature.

Pressure control is achieved using the default Nose-Hoover barostat documented in `fix npt`. There are two ways to control the pressure using this fix. The first method involves using the `ext` keyword along with the `iso` pressure style. With this method, the pressure is controlled by scaling the simulation box isotropically to achieve the average pressure only in the directions specified by `ext`. For example, if the `ext` value is set to `xy`, the average pressure \((P_{xx}+P_{yy})/2\) will be controlled.

This example command will control the total hydrostatic pressure under uniaxial tension:

```
fix f1 all npt/uef temp 0.7 0.7 0.5 iso 1 1 1 erate -0.5 -0.5 ext xyz
```

This example command will control the average stress in compression directions, which would typically correspond to free surfaces under drawing with uniaxial tension:
The second method for pressure control involves setting the normal stresses using the $x$, $y$, and/or $z$ keywords. When using this method, the same pressure must be specified via $P_{\text{start}}$ and $P_{\text{stop}}$ for all dimensions controlled. Any choice of pressure conditions that would cause LAMMPS to compute a deviatoric stress are not permissible and will result in an error. Additionally, all dimensions with controlled stress must have the same applied strain rate. The $\text{ext}$ keyword must be set to the default value ($xyz$) when using this method.

For example, the following commands will work:

```plaintext
fix f3 all npt/uef temp 0.7 0.7 0.5 x 1 1 5 y 1 1 5 erate -0.5 -0.5
fix f4 all npt/uef temp 0.7 0.7 0.5 z 1 1 5 erate 0.5 0.5
```

The following commands will not work:

```plaintext
fix f5 all npt/uef temp 0.7 0.7 0.5 x 1 1 5 z 1 1 5 erate -0.5 -0.5
fix f6 all npt/uef temp 0.7 0.7 0.5 x 1 1 5 z 2 2 5 erate 0.5 0.5
```

These fix computes a temperature and pressure each timestep. To do this, it creates its own computes of style “temp/uef” and “pressure/uef”, as if one of these two sets of commands had been issued:

```plaintext
compute fix-ID_temp group-ID temp/uef
compute fix-ID_press group-ID pressure/uef fix-ID_temp
compute fix-ID_temp all temp/uef
compute fix-ID_press all pressure/uef fix-ID_temp
```

See the `compute temp/uef` and `compute pressure/uef` commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”.

### 18.95.4 Restart, fix_modify, output, run start/stop, minimize info

The fix writes the state of all the thermostat and barostat variables, as well as the cumulative strain applied, to binary restart files. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** It is not necessary to set the $\text{strain}$ keyword when resuming a run from a restart file. Only for resuming from data files, which do not contain the cumulative applied strain, will this keyword be necessary.

This fix can be used with the `fix_modify temp` and `press` options. The temperature and pressure computes used must be of type `temp/uef` and `pressure/uef`.

This fix computes the same global scalar and vector quantities as `fix npt`.

The fix is not invoked during energy minimization.
18.95.5 Restrictions

This fix is part of the USER-UEF package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Due to requirements of the boundary conditions, when the strain keyword is set to zero (or unset), the initial simulation box must be cubic and have style triclinic. If the box is initially of type ortho, use change_box before invoking the fix.

Note: When resuming from restart files, you may need to use box tilt large since lammps has internal criteria from lattice reduction that are not the same as the criteria in the numerical lattice reduction algorithm.

18.95.6 Related commands

fix nvt, fix nvt/sllod, compute temp/uef, compute pressure/uef, dump cfg/uef

18.95.7 Default

The default keyword values specific to this fix are exy = xyz, strain = 0 0. The remaining defaults are the same as for fix npt_fix_nh.html except tchain = 1. The reason for this change is given in fix nvt/sllod.

18.96 fix nph/asphere command

Accelerator Variants: nph/asphere/omp

18.96.1 Syntax

fix ID group-ID nph/asphere args keyword value ...

- ID, group-ID are documented in fix command
- nph/asphere = style name of this fix command
- additional barostat related keyword/value pairs from the fix nph command can be appended
18.96.2 Examples

```
fix 1 all nph/asphere iso 0.0 0.0 1000.0
fix 2 all nph/asphere  x 5.0 5.0 1000.0
fix 2 all nph/asphere  x 5.0 5.0 1000.0 drag 0.2
fix 2 water nph/asphere aniso 0.0 0.0 1000.0 dilate partial
```

18.96.3 Description

Perform constant NPH integration to update position, velocity, orientation, and angular velocity each timestep for aspherical or ellipsoidal particles in the group using a Nose/Hoover pressure barostat. P is pressure; H is enthalpy. This creates a system trajectory consistent with the isenthalpic ensemble.

This fix differs from the `fix nph` command, which assumes point particles and only updates their position and velocity. Additional parameters affecting the barostat are specified by keywords and values documented with the `fix nph` command. See, for example, discussion of the `aniso`, and `dilate` keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPH integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword `dilate` is specified with a value of `partial`, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/asphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/asphere
compute fix-ID_press all pressure fix-ID_temp
```

See the `compute temp/asphere` and `compute pressure` commands for details. Note that the IDs of the new computes are the `fix-ID + underscore + “temp”` or `fix_ID + underscore + “press”`, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp` and `thermo_press`. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.
18.96.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover barostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostatting or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The fix_modify energy option is supported by this fix to add the energy change induced by Nose/Hoover barostatting to the system’s potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the fix nph command.

This fix can ramp its target pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

18.96.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style ellipsoid command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

18.96.6 Related commands

18.97 fix nph/body command

18.97.1 Syntax

\texttt{fix ID group-ID nph/body args keyword value ...}

- ID, group-ID are documented in fix command
- nph/body = style name of this fix command
- additional barostat related keyword/value pairs from the fix nph command can be appended
18.97.2 Examples

```
fix 1 all nph/body iso 0.0 0.0 1000.0
fix 2 all nph/body x 5.0 5.0 1000.0
fix 2 all nph/body x 5.0 5.0 1000.0 drag 0.2
fix 2 water nph/body aniso 0.0 0.0 1000.0 dilate partial
```

18.97.3 Description

Perform constant NPH integration to update position, velocity, orientation, and angular velocity each timestep for body particles in the group using a Nose/Hoover pressure barostat. P is pressure; H is enthalpy. This creates a system trajectory consistent with the isenthalpic ensemble.

This fix differs from the `fix nph` command, which assumes point particles and only updates their position and velocity.

Additional parameters affecting the barostat are specified by keywords and values documented with the `fix nph` command. See, for example, discussion of the `aniso`, and `dilate` keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPH integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword `dilate` is specified with a value of `partial`, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/body” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/body
compute fix-ID_press all pressure fix-ID_temp
```

See the `compute temp/body` and `compute pressure` commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp` and `thermo_press`. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.
18.97.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover barostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostatting or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The fix_modify energy option is supported by this fix to add the energy change induced by Nose/Hoover barostatting to the system’s potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the fix nph command.

This fix can ramp its target pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

18.97.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style body command.

18.98 fix nph/sphere command

Accelerator Variants: nph/sphere/omp

18.98.1 Syntax

| fix ID group-ID nph/sphere args keyword value ... |

- ID, group-ID are documented in fix command
- nph/sphere = style name of this fix command
- keyword = disc
  - disc value = none = treat particles as 2d discs, not spheres
- additional barostat related keyword/value pairs from the fix nph command can be appended
18.98.2 Examples

```
fix 1 all nph/sphere iso 0.0 0.0 1000.0
fix 2 all nph/sphere x 5.0 5.0 1000.0
fix 2 all nph/sphere x 5.0 5.0 1000.0 disc
fix 2 all nph/sphere x 5.0 5.0 1000.0 drag 0.2
fix 2 water nph/sphere aniso 0.0 0.0 1000.0 dilate partial
```

18.98.3 Description

Perform constant NPH integration to update position, velocity, and angular velocity each timestep for finite-size spherical particles in the group using a Nose/Hoover pressure barostat. P is pressure; H is enthalpy. This creates a system trajectory consistent with the isenthalpic ensemble.

This fix differs from the `fix nph` command, which assumes point particles and only updates their position and velocity.

If the `disc` keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the `dimension` keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

Additional parameters affecting the barostat are specified by keywords and values documented with the `fix nph` command. See, for example, discussion of the `aniso`, and `dilate` keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPH integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword `dilate` is specified with a value of `partial`, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/sphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/sphere
compute fix-ID_press all pressure fix-ID_temp
```

See the `compute temp/sphere` and `compute pressure` commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp` and `thermo_press`. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

18.98.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover barostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostatting or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The fix_modify energy option is supported by this fix to add the energy change induced by Nose/Hoover barostatting to the system’s potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the fix nph command.

This fix can ramp its target pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

18.98.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the atom_style sphere command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the disc keyword is only allowed for 2d simulations, as defined by the dimension keyword.

```

18.99.3 Description

This command is a variant of the Nose-Hoover `fix npt` fix style. It performs time integration of the Hugoniostat equations of motion developed by Ravelo et al. (Ravelo). These equations compress the system to a state with average axial stress or pressure equal to the specified target value and that satisfies the Rankine-Hugoniot (RH) jump conditions for steady shocks.

The compression can be performed either hydrostatically (using keyword `iso`, `aniso`, or `tri`) or uniaxially (using keywords `x`, `y`, or `z`). In the hydrostatic case, the cell dimensions change dynamically so that the average axial stress in all three directions converges towards the specified target value. In the uniaxial case, the chosen cell dimension changes...
dynamically so that the average axial stress in that direction converges towards the target value. The other two cell dimensions are kept fixed (zero lateral strain).

This leads to the following additional restrictions on the keywords:

- One and only one of the following keywords should be used: \textit{iso}, \textit{aniso}, \textit{tri}, \textit{x}, \textit{y}, \textit{z}
- The specified initial and final target pressures must be the same.
- The keywords \textit{xy}, \textit{xz}, \textit{yz} may not be used.
- The only admissible value for the couple keyword is \textit{xyz}, which has the same effect as keyword \textit{iso}
- The \textit{temp} keyword must be used to specify the time constant for kinetic energy relaxation, but initial and final target temperature values are ignored.

Essentially, a Hugoniot simulation is an NPT simulation in which the user-specified target temperature is replaced with a time-dependent target temperature $T_t$ obtained from the following equation:

$$T_t - T = \left(\frac{1}{2} \left( P + P_0 \right) \left( V_0 - V \right) + E_0 - E \right) \frac{N_{dof} k_B}{E} = \Delta$$

where $T$ and $T_t$ are the instantaneous and target temperatures, $P$ and $P_0$ are the instantaneous and reference pressures or axial stresses, depending on whether hydrostatic or uniaxial compression is being performed, $V$ and $V_0$ are the instantaneous and reference volumes, $E$ and $E_0$ are the instantaneous and reference internal energy (potential plus kinetic), $N_{dof}$ is the number of degrees of freedom used in the definition of temperature, and $k_B$ is the Boltzmann constant. $\Delta$ is the negative deviation of the instantaneous temperature from the target temperature. When the system reaches a stable equilibrium, the value of $\Delta$ should fluctuate about zero.

The values of $E_0$, $V_0$, and $P_0$ are the instantaneous values at the start of the simulation. These can be overridden using the \texttt{fix_modify} keywords \textit{e0}, \textit{v0}, and \textit{p0} described below.

\textbf{Note:} Unlike the \texttt{fix temp/berendsen} command which performs thermostatting but NO time integration, this fix performs thermostatting/barostatting AND time integration. Thus you should not use any other time integration fix, such as \texttt{fix nve} on atoms to which this fix is applied. Likewise, this fix should not be used on atoms that have their temperature controlled by another fix - e.g. by \texttt{fix langevin} or \texttt{fix temp/rescale} commands.

This fix computes a temperature and pressure at each timestep. To do this, the fix creates its own computes of style \textquote{temp} and \textquote{pressure}, as if one of these two sets of commands had been issued:

```
compute fix-ID_temp group-ID temp  
compute fix-ID_press group-ID pressure fix-ID_temp  
compute fix-ID_temp all temp  
compute fix-ID_press all pressure fix-ID_temp
```

See the \texttt{compute temp} and \texttt{compute pressure} commands for details. Note that the IDs of the new computes are the fix-ID + underscore + \textquote{temp} or fix_ID + underscore + \textquote{pressure}. The group for the new computes is \textquote{all} since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the \texttt{thermo_style} command) with ID = \texttt{thermo_temp} and \texttt{thermo_press}. This means you can change the attributes of this fix’s temperature or pressure via the \texttt{compute_modify} command or print this temperature or pressure during thermodynamic output via the \texttt{thermo_style custom} command using the appropriate compute-ID. It also means that changing attributes of \texttt{thermo_temp} or \texttt{thermo_press} will have no effect on this fix.
Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

\subsection*{18.99.4 Restart, fix\_modify, output, run start/stop, minimize info}

This fix writes the values of $E_0$, $V_0$, and $P_0$, as well as the state of all the thermostat and barostat variables to binary restart files. See the read\_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix\_modify $e0$, $v0$ and $p0$ keywords can be used to define the values of $E_0$, $V_0$, and $P_0$. Note the the values for $e0$ and $v0$ are extensive, and so must correspond to the total energy and volume of the entire system, not energy and volume per atom. If any of these quantities are not specified, then the instantaneous value in the system at the start of the simulation is used.

The fix\_modify temp and press options are supported by these fixes. You can use them to assign a compute you have defined to this fix which will be used in its thermostating or barostatting procedure, as described above. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The fix\_modify energy option is supported by these fixes to add the energy change induced by Nose/Hoover thermostatting and barostatting to the system’s potential energy as part of thermodynamic output. Either way, this energy is *not* included in the definition of internal energy $E$ when calculating the value of Delta in the above equation.

These fixes compute a global scalar and a global vector of quantities, which can be accessed by various output commands. The scalar value calculated by these fixes is “extensive”; the vector values are “intensive”.

The scalar is the cumulative energy change due to the fix.

The vector stores three quantities unique to this fix ($\Delta$, $U_s$, and $u_p$), followed by all the internal Nose/Hoover thermostat and barostat variables defined for fix\_npt. Delta is the deviation of the temperature from the target temperature, given by the above equation. $U_s$ and $u_p$ are the shock and particle velocity corresponding to a steady shock calculated from the RH conditions. They have units of distance/time.

\subsection*{18.99.5 Restrictions}

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

All the usual restrictions for fix\_npt apply, plus the additional ones mentioned above.
18.99.6 Related commands

fix 2 water npt/asphere temp 300.0 300.0 100.0 aniso 0.0 0.0 1000.0 dilate partial
```

18.100.3 Description

Perform constant NPT integration to update position, velocity, orientation, and angular velocity each timestep for aspherical or ellipsoidal particles in the group using a Nose/Hoover temperature thermostat and Nose/Hoover pressure barostat. P is pressure; T is temperature. This creates a system trajectory consistent with the isothermal-isobaric ensemble.

This fix differs from the `fix npt` command, which assumes point particles and only updates their position and velocity. The thermostat is applied to both the translational and rotational degrees of freedom for the aspherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

Additional parameters affecting the thermostat and barostat are specified by keywords and values documented with the `fix npt` command. See, for example, discussion of the `temp`, `iso`, `aniso`, and `dilate` keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPT integration.
Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/asphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/asphere
compute fix-ID_press all pressure fix-ID_temp
```

See the `compute temp/asphere` and `compute pressure` commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = *thermo_temp* and *thermo_press*. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of *thermo_temp* or *thermo_press* will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with `compute commands` that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

### 18.100.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat and barostat to *binary restart files*. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The `fix_modify temp` and `press` options are supported by this fix. You can use them to assign a `compute` you have defined to this fix which will be used in its thermostatting or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.
The `fix_modify energy` option is supported by this fix to add the energy change induced by Nose/Hoover thermostatting and barostatting to the system’s potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the `fix npt` command.

This fix can ramp its target temperature and pressure over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

This fix is not invoked during energy minimization.

### 18.100.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the `atom_style ellipsoid` command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

### 18.100.6 Related commands

`fix npt, fix nve_asphere, fix nvt_asphere, fix_modify`

### 18.100.7 Default

none

### 18.101 fix npt/body command

#### 18.101.1 Syntax

`fix ID group-ID npt/body keyword value ...`

- ID, group-ID are documented in `fix` command
- npt/body = style name of this fix command
- additional thermostat and barostat related keyword/value pairs from the `fix npt` command can be appended

#### 18.101.2 Examples

```
fix 1 all npt/body temp 300.0 300.0 100.0 iso 0.0 0.0 1000.0
fix 2 all npt/body temp 300.0 300.0 100.0 x 5.0 5.0 1000.0
fix 2 all npt/body temp 300.0 300.0 100.0 x 5.0 5.0 1000.0 drag 0.2
fix 2 water npt/body temp 300.0 300.0 100.0 aniso 0.0 0.0 1000.0 dilate partial
```
18.101.3 Description

Perform constant NPT integration to update position, velocity, orientation, and angular velocity each timestep for body particles in the group using a Nose/Hoover temperature thermostat and Nose/Hoover pressure barostat. P is pressure; T is temperature. This creates a system trajectory consistent with the isothermal-isobaric ensemble.

This fix differs from the fix npt command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the body particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

Additional parameters affecting the thermostat and barostat are specified by keywords and values documented with the fix npt command. See, for example, discussion of the temp, iso, aniso, and dilate keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPT integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword dilate is specified with a value of partial, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/body” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/body
compute fix-ID_press all pressure fix-ID_temp
```

See the compute temp/body and compute pressure commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the thermo_style command) with ID = thermo_temp and thermo_press. This means you can change the attributes of this fix’s temperature or pressure via the compute_modify command or print this temperature or pressure during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp or thermo_press will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with compute commands that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the fix_modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute commands to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 18.101.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat and barostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostatting or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The fix_modify energy option is supported by this fix to add the energy change induced by Nose/Hoover thermostatting and barostatting to the system’s potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the fix npt command.

This fix can ramp its target temperature and pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

### 18.101.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style body command.

### 18.101.6 Related commands

fix npt, fix nve_body, fix nvt_body, fix_modify

### 18.101.7 Default

### 18.102 fix npt/cauchy command

#### 18.102.1 Syntax

```
fix ID group-ID style_name keyword value ...
```

- ID, group-ID are documented in fix command
- style_name = npt/cauchy
- one or more keyword/value pairs may be appended
• keyword = temp or iso or aniso or tri or x or y or z or xy or yz or xz or couple or tchain or pchain or mtk or tloop or ploop or nreset or drag or dilate or scalexy or scaleyz or scalexz or flip or fixedpoint

  temp values = Tstart Tstop Tdamp
  Tstart, Tstop = external temperature at start/end of run
  Tdamp = temperature damping parameter (time units)

  iso or aniso or tri values = Pstart Pstop Pdamp
  Pstart, Pstop = scalar external pressure at start/end of run (pressure units)
  Pdamp = pressure damping parameter (time units)

  x or y or z or xy or yz or xz values = Pstart Pstop Pdamp
  Pstart, Pstop = external stress tensor component at start/end of run (pressure units)
  Pdamp = stress damping parameter (time units)

  couple = none or xyz or xy or yz or xz

  tchain value = N
  N = length of thermostat chain (1 = single thermostat)

  pchain values = N
  N length of thermostat chain on barostat (0 = no thermostat)

  mtk value = yes or no = add in MTK adjustment term or not

  tloop value = M
  M = number of sub-cycles to perform on thermostat

  ploop value = M
  M = number of sub-cycles to perform on barostat thermostat

  nreset value = reset reference cell every this many timesteps

  drag value = Df
  Df = drag factor added to barostat/thermostat (0.0 = no drag)

  dilate value = dilate-group-ID
  dilate-group-ID = only dilate atoms in this group due to barostat

  scalexy value = yes or no = scale xy with ly
  scaleyz value = yes or no = scale yz with lz
  scalexz value = yes or no = scale xz with lz

  flip value = yes or no = allow or disallow box flips when it becomes highly skewed

  alpha value = strength of Cauchy stress control parameter

  continue value = yes or no = whether of not to continue from a previous run

  fixedpoint values = x y z
  x, y, z = perform barostat dilation/contraction around this point (distance units)
18.102.2 Examples

```
fix 1 water npt/cauchy temp 300.0 300.0 100.0 iso 0.0 0.0 1000.0 alpha 0.001
```

18.102.3 Description

This command performs time integration on Nose-Hoover style non-Hamiltonian equations of motion which are designed to generate positions and velocities sampled from the isothermal-isobaric (npt) ensembles. This updates the position and velocity for atoms in the group each timestep and the box dimensions.

The thermostatting and barostatting is achieved by adding some dynamic variables which are coupled to the particle velocities (thermostatting) and simulation domain dimensions (barostatting). In addition to basic thermostatting and barostatting, this fix can also create a chain of thermostats coupled to the particle thermostat, and another chain of barostats coupled to the barostat variables. The barostat can be coupled to the overall box volume, or to individual dimensions, including the $xy$, $xz$, and $yz$ tilt dimensions. The external pressure of the barostat can be specified as either a scalar pressure (isobaric ensemble) or as components of a symmetric stress tensor (constant stress ensemble). When used correctly, the time-averaged temperature and stress tensor of the particles will match the target values specified by $T_{start}/T_{stop}$ and $P_{start}/P_{stop}$.

The equations of motion used are those of Shinoda et al in [Shinoda], which combine the hydrostatic equations of Martyna, Tobias and Klein in [Martyna] with the strain energy proposed by Parrinello and Rahman in [Parrinello]. The time integration schemes closely follow the time-reversible measure-preserving Verlet and rRESPA integrators derived by Tuckerman et al in [Tuckerman].

The thermostat parameters are specified using the `temp` keyword. Other thermostat-related keywords are `tchain`, `tloop`, and `drag`, which are discussed below.

The thermostat is applied to only the translational degrees of freedom for the particles. The translational degrees of freedom can also have a bias velocity removed before thermostatting takes place; see the description below. The desired temperature at each timestep is a ramped value during the run from $T_{start}$ to $T_{stop}$. The $Tdamp$ parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 10.0 means to relax the temperature in a timespan of (roughly) 10 time units (e.g. $\tau$ or fs or ps - see the `units` command). The atoms in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the integration.

**Note:** A Nose-Hoover thermostat will not work well for arbitrary values of $Tdamp$. If $Tdamp$ is too small, the temperature can fluctuate wildly; if it is too large, the temperature will take a very long time to equilibrate. A good choice for many models is a $Tdamp$ of around 100 timesteps. Note that this is NOT the same as 100 time units for most `units` settings.

The barostat parameters are specified using one or more of the `iso`, `aniso`, `tri`, `x`, `y`, `z`, `xy`, `xz`, `yz`, and `couple` keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation.

Other barostat-related keywords are `pchain`, `mtk`, `ploop`, `nreset`, `drag`, and `dilate`, which are discussed below.

Orthogonal simulation boxes have 3 adjustable dimensions ($x,y,z$). Triclinic (non-orthogonal) simulation boxes have 6 adjustable dimensions ($x,y,z,xy,xz,yz$). The `create_box`, `read data`, and `read_restart` commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the $xy,xz,yz$ tilt factors.
The target pressures for each of the 6 components of the stress tensor can be specified independently via the \( x \), \( y \), \( z \), \( xy \), \( xz \), \( yz \) keywords, which correspond to the 6 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from \( P_{\text{start}} \) to \( P_{\text{stop}} \). If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the \( y \) keyword is used, the \( y \)-box length will change. If the \( xy \) keyword is used, the \( xy \) tilt factor will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the \texttt{fix deform} command.

Note that in order to use the \( xy \), \( xz \), or \( yz \) keywords, the simulation box must be triclinic, even if its initial tilt factors are 0.0.

For all barostat keywords, the \( P_{\text{damp}} \) parameter operates like the \( T_{\text{damp}} \) parameter, determining the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (e.g. \( \tau \) or fs or ps - see the \texttt{units} command).

\begin{itemize}
  \item \textbf{Note:} A Nose-Hoover barostat will not work well for arbitrary values of \( P_{\text{damp}} \). If \( P_{\text{damp}} \) is too small, the pressure and volume can fluctuate wildly; if it is too large, the pressure will take a very long time to equilibrate. A good choice for many models is a \( P_{\text{damp}} \) of around 1000 timesteps. However, note that \( P_{\text{damp}} \) is specified in time units, and that timesteps are NOT the same as time units for most \texttt{units} settings.
\end{itemize}

Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword \texttt{dilate} is specified with a \texttt{dilate-group-ID} for a group that represents a subset of the atoms. This can be useful, for example, to leave the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid. This option should be used with care, since it can be unphysical to dilate some atoms and not others, because it can introduce large, instantaneous displacements between a pair of atoms (one dilated, one not) that are far from the dilation origin. Also note that for atoms not in the fix group, a separate time integration fix like \texttt{fix nve} or \texttt{fix nvt} can be used on them, independent of whether they are dilated or not.

The \texttt{couple} keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, \( xz \) means the \( P_{xx} \) and \( P_{zz} \) components of the stress tensor are coupled. \( Xyz \) means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The \( P_{\text{start}} \), \( P_{\text{stop}} \), \( P_{\text{damp}} \) parameters for any coupled dimensions must be identical. \texttt{Couple xyz} can be used for a 2d simulation; the \( z \) dimension is simply ignored.

The \texttt{iso}, \texttt{aniso}, and \texttt{tri} keywords are simply shortcuts that are equivalent to specifying several other keywords together. The keyword \texttt{iso} means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “\texttt{iso Pstart Pstop Pdamp}” is the same as specifying these 4 keywords:

\begin{verbatim}
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple xyz
\end{verbatim}

The keyword \texttt{aniso} means \( x \), \( y \), and \( z \) dimensions are controlled independently using the \( P_{xx} \), \( P_{yy} \), and \( P_{zz} \) components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “\texttt{aniso Pstart Pstop Pdamp}” is the same as specifying these 4 keywords:
The keyword \textit{tri} means \(x, y, z, xy, xz,\) and \(yz\) dimensions are controlled independently using their individual stress components as the driving forces, and the specified scalar pressure as the external normal stress. Using “\textit{tri Pstart Pstop Pdamp}” is the same as specifying these 7 keywords:

\begin{verbatim}
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
xy 0.0 0.0 Pdamp
yz 0.0 0.0 Pdamp
xz 0.0 0.0 Pdamp
couple none
\end{verbatim}

In some cases (e.g. for solids) the pressure (volume) and/or temperature of the system can oscillate undesirably when a Nose/Hoover barostat and thermostat is applied. The optional \textit{drag} keyword will damp these oscillations, although it alters the Nose/Hoover equations. A value of 0.0 (no drag) leaves the Nose/Hoover formalism unchanged. A non-zero value adds a drag term; the larger the value specified, the greater the damping effect. Performing a short run and monitoring the pressure and temperature is the best way to determine if the drag term is working. Typically a value between 0.2 to 2.0 is sufficient to damp oscillations after a few periods. Note that use of the drag keyword will interfere with energy conservation and will also change the distribution of positions and velocities so that they do not correspond to the nominal NVT, NPT, or NPH ensembles.

An alternative way to control initial oscillations is to use chain thermostats. The keyword \textit{tchain} determines the number of thermostats in the particle thermostat. A value of 1 corresponds to the original Nose-Hoover thermostat. The keyword \textit{pchain} specifies the number of thermostats in the chain thermostatting the barostat degrees of freedom. A value of 0 corresponds to no thermostatting of the barostat variables.

The \textit{mtk} keyword controls whether or not the correction terms due to Martyna, Tuckerman, and Klein are included in the equations of motion (Martyna). Specifying \textit{no} reproduces the original Hoover barostat, whose volume probability distribution function differs from the true NPT and NPH ensembles by a factor of \(1/V\). Hence using \textit{yes} is more correct, but in many cases the difference is negligible.

The keyword \textit{tloop} can be used to improve the accuracy of integration scheme at little extra cost. The initial and final updates of the thermostat variables are broken up into \textit{tloop} sub-steps, each of length \(dt\). This corresponds to using a first-order Suzuki-Yoshida scheme (Tuckerman). The keyword \textit{ploop} does the same thing for the barostat thermostat.

The keyword \textit{nreset} controls how often the reference dimensions used to define the strain energy are reset. If this keyword is not used, or is given a value of zero, then the reference dimensions are set to those of the initial simulation domain and are never changed. If the simulation domain changes significantly during the simulation, then the final average pressure tensor will differ significantly from the specified values of the external stress tensor. A value of \textit{nstep} means that every \textit{nstep} timesteps, the reference dimensions are set to those of the current simulation domain.

The \textit{scaleyz}, \textit{scalexz}, and \textit{scalexy} keywords control whether or not the corresponding tilt factors are scaled with the associated box dimensions when barostatting triclinic periodic cells. The default values \textit{yes} will turn on scaling, which corresponds to adjusting the linear dimensions of the cell while preserving its shape. Choosing \textit{no} ensures that the tilt factors are not scaled with the box dimensions. See below for restrictions and default values in different situations. In older versions of LAMMPS, scaling of tilt factors was not performed. The old behavior can be recovered by setting all three scale keywords to \textit{no}.

The \textit{flip} keyword allows the tilt factors for a triclinic box to exceed half the distance of the parallel box length, as discussed below. If the \textit{flip} value is set to \textit{yes}, the bound is enforced by flipping the box when it is exceeded. If the \textit{flip}
value is set to no, the tilt will continue to change without flipping. Note that if applied stress induces large deformations (e.g. in a liquid), this means the box shape can tilt dramatically and LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor’s irregular-shaped sub-domain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

The fixedpoint keyword specifies the fixed point for barostat volume changes. By default, it is the center of the box. Whatever point is chosen will not move during the simulation. For example, if the lower periodic boundaries pass through (0,0,0), and this point is provided to fixedpoint, then the lower periodic boundaries will remain at (0,0,0), while the upper periodic boundaries will move twice as far. In all cases, the particle trajectories are unaffected by the chosen value, except for a time-dependent constant translation of positions.

---

**Note:** Using a barostat coupled to tilt dimensions $xy$, $xz$, $yz$ can sometimes result in arbitrarily large values of the tilt dimensions, i.e. a dramatically deformed simulation box. LAMMPS allows the tilt factors to grow a small amount beyond the normal limit of half the box length (0.6 times the box length), and then performs a box “flip” to an equivalent periodic cell. See the discussion of the flip keyword above, to allow this bound to be exceeded, if desired.

The flip operation is described in more detail in the doc page for fix deform. Both the barostat dynamics and the atom trajectories are unaffected by this operation. However, if a tilt factor is incremented by a large amount (1.5 times the box length) on a single timestep, LAMMPS can not accommodate this event and will terminate the simulation with an error. This error typically indicates that there is something badly wrong with how the simulation was constructed, such as specifying values of $P_{\text{start}}$ that are too far from the current stress value, or specifying a timestep that is too large. Triclinic barostatting should be used with care. This also is true for other barostat styles, although they tend to be more forgiving of insults. In particular, it is important to recognize that equilibrium liquids can not support a shear stress and that equilibrium solids can not support shear stresses that exceed the yield stress.

One exception to this rule is if the first dimension in the tilt factor (x for $xy$) is non-periodic. In that case, the limits on the tilt factor are not enforced, since flipping the box in that dimension does not change the atom positions due to non-periodicity. In this mode, if you tilt the system to extreme angles, the simulation will simply become inefficient due to the highly skewed simulation box.

**Note:** Unlike the fix temp/berendsen command which performs thermostatting but NO time integration, this fix performs thermostatting/barostatting AND time integration. Thus you should not use any other time integration fix, such as fix nve on atoms to which this fix is applied. Likewise, fix npt/cauchy should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by fix langevin or fix temp/rescale commands.

See the Howto thermostat and Howto barostat doc pages for a discussion of different ways to compute temperature and perform thermostatting and barostatting.

This fix compute a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp” and “pressure”, as if one of these sets of commands had been issued:

```
compute fix-ID_temp all temp
compute fix-ID_press all pressure fix-ID_temp
```

The group for both the new temperature and pressure compute is “all” since pressure is computed for the entire system. See the compute temp and compute pressure commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”.

Note that these are NOT the computes used by thermodynamic output (see the thermo_style command) with ID = thermo_temp and thermo_press. This means you can change the attributes of these fix’s temperature or pressure via the compute_modify command. Or you can print this temperature or pressure during thermodynamic output.
via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

Like other fixes that perform thermostatting, fix npt/cauchy can be used with `compute commands` that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

This fix can be used with either the `verlet` or `respa` integrators. When using this fix with `respa`, LAMMPS uses an integrator constructed according to the following factorization of the Liouville propagator (for two rRESPA levels):

\[
\exp (iL\Delta t) = \hat{E} \exp \left( iL_{T_{-\text{baro}}} \frac{\Delta t}{2} \right) \exp \left( iL_{T_{-\text{part}}} \frac{\Delta t}{2} \right) \exp \left( iL_{E_2} \frac{\Delta t}{2} \right) \exp \left( iL_{(2)} \frac{\Delta t}{2} \right) \\
\times \left[ \exp \left( iL_2^{(1)} \frac{\Delta t}{2n} \right) \exp \left( iL_{e_1} \frac{\Delta t}{2n} \right) \exp \left( iL_{e_2} \frac{\Delta t}{2n} \right) \exp \left( iL_{e_1} \frac{\Delta t}{2n} \right) \exp \left( iL_{e_1} \frac{\Delta t}{2n} \right) \right]^n \\
\times \exp \left( iL_2^{(2)} \frac{\Delta t}{2} \right) \exp \left( iL_{e_2} \frac{\Delta t}{2} \right) \exp \left( iL_{T_{-\text{part}}} \frac{\Delta t}{2} \right) \exp \left( iL_{T_{-\text{baro}}} \frac{\Delta t}{2} \right) \\
+ O(\Delta t^3)
\]

This factorization differs somewhat from that of Tuckerman et al, in that the barostat is only updated at the outermost rRESPA level, whereas Tuckerman’s factorization requires splitting the pressure into pieces corresponding to the forces computed at each rRESPA level. In theory, the latter method will exhibit better numerical stability. In practice, because Pdamp is normally chosen to be a large multiple of the outermost rRESPA timestep, the barostat dynamics are not the limiting factor for numerical stability. Both factorizations are time-reversible and can be shown to preserve the phase space measure of the underlying non-Hamiltonian equations of motion.

**Note:** Under NPT dynamics, for a system with zero initial total linear momentum, the total momentum fluctuates close to zero. It may occasionally undergo brief excursions to non-negligible values, before returning close to zero. Over long simulations, this has the effect of causing the center-of-mass to undergo a slow random walk. This can be mitigated by resetting the momentum at infrequent intervals using the `fix momentum` command.

### 18.102.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of all the thermostat and barostat variables to binary restart files. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The `fix_modify temp` and `press` options are supported by this fix. You can use them to assign a `compute` you have defined to this fix which will be used in its thermostatting or barostatting procedure, as described above. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

**Note:** If both the `temp` and `press` keywords are used in a single thermo_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a pressure compute defines its own temperature compute as an argument when it is specified. The `temp` keyword will override this (for the pressure
compute being used by fix npt), but only if the temp keyword comes after the press keyword. If the temp keyword comes before the press keyword, then the new pressure compute specified by the press keyword will be unaffected by the temp setting.

The fix_modify energy option is supported by this fix to add the energy change induced by Nose/Hoover thermostatting and barostatting to the system’s potential energy as part of thermodynamic output. This fix computes a global scalar and a global vector of quantities, which can be accessed by various output commands. The scalar value calculated by this fix is “extensive”; the vector values are “intensive”.

The scalar is the cumulative energy change due to the fix. The vector stores internal Nose/Hoover thermostat and barostat variables. The number and meaning of the vector values depends on which fix is used and the settings for keywords tchain and pchain, which specify the number of Nose/Hoover chains for the thermostat and barostat. If no thermostatting is done, then tchain is 0. If no barostatting is done, then pchain is 0. In the following list, “ndof” is 0, 1, 3, or 6, and is the number of degrees of freedom in the barostat. Its value is 0 if no barostat is used, else its value is 6 if any off-diagonal stress tensor component is barostatted, else its value is 1 if couple xyz is used or couple xy for a 2d simulation, otherwise its value is 3.

The order of values in the global vector and their meaning is as follows. The notation means there are tchain values for eta, followed by tchain for eta_dot, followed by ndof for omega, etc:

- \( \eta[tchain] \) = particle thermostat displacements (unitless)
- \( \eta_{dot}[tchain] \) = particle thermostat velocities (1/time units)
- \( \omega[ndof] \) = barostat displacements (unitless)
- \( \omega_{dot}[ndof] \) = barostat velocities (1/time units)
- \( \eta_{pchain} \) = barostat thermostat displacements (unitless)
- \( \eta_{pchain}_{dot} \) = barostat thermostat velocities (1/time units)
- \( PE_{\eta[tchain]} \) = potential energy of each particle thermostat displacement (energy units)
- \( KE_{\eta_{dot}[tchain]} \) = kinetic energy of each particle thermostat velocity (energy units)
- \( PE_{\omega[ndof]} \) = potential energy of each barostat displacement (energy units)
- \( KE_{\omega_{dot}[ndof]} \) = kinetic energy of each barostat velocity (energy units)
- \( PE_{\eta_{pchain}} \) = potential energy of each barostat thermostat displacement (energy units)
- \( KE_{\eta_{pchain}_{dot}} \) = kinetic energy of each barostat thermostat velocity (energy units)
- \( PE_{strain[1]} \) = scalar strain energy (energy units)

This fix can ramp its external temperature and pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.
18.102.5 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

X, y, z cannot be barostatted if the associated dimension is not periodic. Xy, xz, and yz can only be barostatted if the simulation domain is triclinic and the second dimension in the keyword (y dimension in xy) is periodic. Z, xz, and yz cannot be barostatted for 2D simulations. The create_box, read_data, and read_restart commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

For the temp keyword, the final Tstop cannot be 0.0 since it would make the external T = 0.0 at some timestep during the simulation which is not allowed in the Nose/Hoover formulation.

The scaleyz yes and scalexz yes keyword/value pairs can not be used for 2D simulations. scaleyz yes, scalexz yes, and scalexy yes options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords tri, yz, xz, and xy.

The alpha keyword modifies the barostat as per Miller et al. (Miller)“#nc-Miller” so that the Cauchy stress is controlled. alpha is the non-dimensional parameter, typically set to 0.001 or 0.01 that determines how aggressively the algorithm drives the system towards the set Cauchy stresses. Larger values of alpha will modify the system more quickly, but can lead to instabilities. Smaller values will lead to longer convergence time. Since alpha also influences how much the stress fluctuations deviate from the equilibrium fluctuations, it should be set as small as possible.

A continue value of yes indicates that the fix is subsequent to a previous run with the npt/cauchy fix, and the intention is to continue from the converged stress state at the end of the previous run. This may be required, for example, when implementing a multi-step loading/unloading sequence over several fixes.

Setting alpha to zero is not permitted. To “turn off” the cauchystat control and thus restore the equilibrium stress fluctuations, two subsequent fixes should be used. In the first, fix npt/cauchy is used and the simulation box equilibrates to the correct shape for the desired stresses. In the second, fix npt is used instead which uses the original Parrinello-Rahman algorithm, but now with the corrected simulation box shape from using fix npt/cauchy.

This fix can be used with dynamic groups as defined by the group command. Likewise it can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

18.102.6 Related commands

fix nve, fix_modify, run_style

18.102.7 Default

The keyword defaults are tchain = 3, pchain = 3, mtk = yes, tloop = ploop = 1, nreset = 0, drag = 0.0, dilate = all, couple = none, cauchystat = no, scaleyz = scalexz = scalexy = yes if periodic in second dimension and not coupled to barostat, otherwise no.

18.103 fix npt/sphere command

Accelerator Variants: npt/sphere/omp

18.103.1 Syntax

```
fix ID group-ID npt/sphere keyword value ...
```

- ID, group-ID are documented in fix command npt/sphere = style name of this fix command zero or more keyword/value pairs may be appended
- keyword = disc
disc value = none = treat particles as 2d discs, not spheres
- additional thermostat and barostat related keyword/value pairs from the fix npt command can be appended

18.103.2 Examples

```
fix 1 all npt/sphere temp 300.0 300.0 100.0 iso 0.0 0.0 1000.0
fix 2 all npt/sphere temp 300.0 300.0 100.0 x 5.0 5.0 1000.0
fix 2 all npt/sphere temp 300.0 300.0 100.0 x 5.0 5.0 1000.0 disc
fix 2 all npt/sphere temp 300.0 300.0 100.0 x 5.0 5.0 1000.0 drag 0.2
fix 2 water npt/sphere temp 300.0 300.0 100.0 aniso 0.0 0.0 1000.0 dilate partial
```

18.103.3 Description

Perform constant NPT integration to update position, velocity, and angular velocity each timestep for finite-size spherical particles in the group using a Nose/Hoover temperature thermostat and Nose/Hoover pressure barostat. P is pressure; T is temperature. This creates a system trajectory consistent with the isothermal-isobaric ensemble.

This fix differs from the fix npt command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the spherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

If the disc keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the dimension keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

Additional parameters affecting the thermostat and barostat are specified by keywords and values documented with the fix npt command. See, for example, discussion of the temp, iso, aniso, and dilate keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPT integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword dilate is specified with a value of partial, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.
This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/sphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/sphere
compute fix-ID_press all pressure fix-ID_temp
```

See the `compute temp/sphere` and `compute pressure` commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp` and `thermo_press`. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with `compute commands` that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

### 18.103.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat and barostat to `binary restart files`. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The `fix_modify temp` and `press` options are supported by this fix. You can use them to assign a `compute` you have defined to this fix which will be used in its thermostatting or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The `fix_modify energy` option is supported by this fix to add the energy change induced by Nose/Hoover thermostatting and barostatting to the system’s potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the `fix npt` command.

This fix can ramp its target temperature and pressure over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

This fix is not invoked during `energy minimization`.
18.103.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the atom_style sphere command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the disc keyword is only allowed for 2d simulations, as defined by the dimension keyword.

18.104 fix numdiff command

18.104.1 Syntax

fix ID group-ID numdiff Nevery delta

• ID, group-ID are documented in fix command
• numdiff = style name of this fix command
• Nevery = calculate force by finite difference every this many timesteps
• delta = finite difference displacement length (distance units)

18.104.2 Examples

fix 1 all numdiff 1 0.0001
fix 1 all numdiff 10 1e-6
fix 1 all numdiff 100 0.01

18.104.3 Description

Calculate forces through finite difference calculations of energy versus position. These forces can be compared to analytic forces computed by pair styles, bond styles, etc. This can be useful for debugging or other purposes.

The group specified with the command means only atoms within the group have their averages computed. Results are set to 0.0 for atoms not in the group.

This fix performs a loop over all atoms in the group. For each atom and each component of force it adds delta to the position, computes the new energy of the entire system, subtracts delta from the original position and again computes the new energy of the system. It then restores the original position. That component of force is calculated as the difference in energy divided by two times delta.
It is important to choose a suitable value for delta, the magnitude of atom displacements that are used to generate finite difference approximations to the exact forces. For typical systems, a value in the range of 1 part in 1e4 to 1e5 of the typical separation distance between atoms in the liquid or solid state will be sufficient. However, the best value will depend on a multitude of factors including the stiffness of the interatomic potential, the thermodynamic state of the material being probed, and so on. The only way to be sure that you have made a good choice is to do a sensitivity study on a representative atomic configuration, sweeping over a wide range of values of delta. If delta is too small, the output forces will vary erratically due to truncation effects. If delta is increased beyond a certain point, the output forces will start to vary smoothly with delta, due to growing contributions from higher order derivatives. In between these two limits, the numerical force values should be largely independent of delta.

The cost of each energy evaluation is essentially the cost of an MD timestep. Thus invoking this fix once for a 3d system has a cost of 6N timesteps, where N is the total number of atoms in the system (assuming all atoms are included in the group). So this fix can be very expensive to use for large systems.

The \textit{Nevery} argument specifies on what timesteps the force will be used calculated by finite difference. The \textit{delta} argument specifies the positional displacement each atom will undergo.

18.104.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to \textit{binary restart files}. None of the \textit{fix\_modify} options are relevant to this fix. This fix produces a per-atom array which can be accessed by various \textit{output commands}, which stores the components of the force on each atom as calculated by finite difference. The per-atom values can only be accessed on timesteps that are multiples of \textit{Nevery} since that is when the finite difference forces are calculated.

No parameter of this fix can be used with the \textit{start/stop} keywords of the \textit{run} command. This fix is invoked during \textit{energy minimization}.

fix 1 all nve/dot
```

18.110.3 Description

Apply a rigid-body integrator as described in (Davidchack) to a group of atoms, but without Langevin dynamics. This command performs Molecular dynamics (MD) via a velocity-Verlet algorithm and an evolution operator that rotates the quaternion degrees of freedom, similar to the scheme outlined in (Miller).

This command is the equivalent of the `fix nve/dotc/langevin` without damping and noise and can be used to determine the stability range in a NVE ensemble prior to using the Langevin-type DOTC-integrator (see also `fix nve/dotc/langevin`). The command is equivalent to the `fix nve`. The particles are always considered to have a finite size.

An example input file can be found in /examples/USER/cgdna/examples/duplex1/. Further details of the implementation and stability of the integrator are contained in (Henrich). The preprint version of the article can be found here.

18.110.4 Restrictions

These pair styles can only be used if LAMMPS was built with the USER-CGDNA package and the MOLECULE and ASPHERE package. See the Build package doc page for more info.

LAMMPS Documentation

- Tstart, Tstop = desired temperature at start/end of run (temperature units)
- damp = damping parameter (time units)
- seed = random number seed to use for white noise (positive integer)
- keyword = angmom

  angmom value = factor
  factor = do thermostat rotational degrees of freedom via the angular momentum and apply numeric scale factor as discussed below

18.111.2 Examples

```
fix 1 all nve/dotc/langevin 1.0 1.0 0.03 457145 angmom 10
fix 1 all nve/dotc/langevin 0.1 0.1 78.9375 457145 angmom 10
```

18.111.3 Description

Apply a rigid-body Langevin-type integrator of the kind “Langevin C” as described in (Davidchack) to a group of atoms, which models an interaction with an implicit background solvent. This command performs Brownian dynamics (BD) via a technique that splits the integration into a deterministic Hamiltonian part and the Ornstein-Uhlenbeck process for noise and damping. The quaternion degrees of freedom are updated though an evolution operator which performs a rotation in quaternion space, preserves the quaternion norm and is akin to (Miller).

In terms of syntax this command has been closely modelled on the fix langevin and its angmom option. But it combines the fix nve and the fix langevin in one single command. The main feature is improved stability over the standard integrator, permitting slightly larger timestep sizes.

**Note:** Unlike the fix langevin this command performs also time integration of the translational and quaternion degrees of freedom.

The total force on each atom will have the form:

\[
F = F_c + F_f + F_r
\]

\[
F_f = -\frac{m}{damp}v
\]

\[
F_r \propto \sqrt{\frac{k_B T m}{damp}}
\]

\(F_c\) is the conservative force computed via the usual inter-particle interactions (pair_style, bond_style, etc). The \(F_f\) and \(F_r\) terms are implicitly taken into account by this fix on a per-particle basis.

\(F_f\) is a frictional drag or viscous damping term proportional to the particle’s velocity. The proportionality constant for each atom is computed as \(\frac{m}{damp}\), where \(m\) is the mass of the particle and damp is the damping factor specified by the user.

\(F_r\) is a force due to solvent atoms at a temperature \(T\) randomly bumping into the particle. As derived from the fluctuation/dissipation theorem, its magnitude as shown above is proportional to \(\sqrt{\frac{k_B T m}{damp}}\), where \(k_B\) is the Boltzmann constant, \(T\) is the desired temperature, \(m\) is the mass of the particle, \(dt\) is the timestep size, and damp is the damping factor. Random numbers are used to randomize the direction and magnitude of this force as described in (Dunweg), where a uniform random number is used (instead of a Gaussian random number) for speed.
$T_{\text{start}}$ and $T_{\text{stop}}$ have to be constant values, i.e. they cannot be variables. If used together with the oxDNA force field for coarse-grained simulation of DNA please note that $T = 0.1$ in oxDNA units corresponds to $T = 300$ K.

The $\text{damp}$ parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 0.03 means to relax the temperature in a timespan of (roughly) 0.03 time units $\tau$ (see the $\text{units}$ command). The damp factor can be thought of as inversely related to the viscosity of the solvent, i.e. a small relaxation time implies a high-viscosity solvent and vice versa. See the discussion about gamma and viscosity in the documentation for the $\text{fix viscous}$ command for more details. Note that the value 78.9375 in the second example above corresponds to a diffusion constant, which is about an order of magnitude larger than realistic ones. This has been used to sample configurations faster in Brownian dynamics simulations.

The random # seed must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The keyword/value option has to be used in the following way:

This fix has to be used together with the $\text{angmom}$ keyword. The particles are always considered to have a finite size. The keyword $\text{angmom}$ enables thermostatting of the rotational degrees of freedom in addition to the usual translational degrees of freedom.

The scale factor after the $\text{angmom}$ keyword gives the ratio of the rotational to the translational friction coefficient.

An example input file can be found in examples/USER/cgdna/examples/duplex2/. Further details of the implementation and stability of the integrators are contained in (Henrich). The preprint version of the article can be found here.

### 18.111.4 Restrictions

These pair styles can only be used if LAMMPS was built with the USER-CGDNA package and the MOLECULE and ASPHERE package. See the Build package doc page for more info.

### 18.111.5 Related commands

fix nve, fix langevin, fix nve/dot, bond_style oxdna/fene, bond_style oxdna2/fene, pair_style oxdna/excv, pair_style oxdna2/excv

none

18.112 fix nve/eff command

18.112.1 Syntax

```plaintext
fix ID group-ID nve/eff
```

- ID, group-ID are documented in `fix` command
- nve/eff = style name of this fix command

18.112.2 Examples

```plaintext
fix 1 all nve/eff
```

18.112.3 Description

Perform constant NVE integration to update position and velocity for nuclei and electrons in the group for the electron force field model. V is volume; E is energy. This creates a system trajectory consistent with the microcanonical ensemble.

The operation of this fix is exactly like that described by the `fix nve` command, except that the radius and radial velocity of electrons are also updated.

18.112.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various `output commands`. No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

18.112.5 Restrictions

This fix is part of the USER-EFF package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

18.112.6 Related commands

`fix nve, fix nvt/eff, fix npt/eff`

18.112.7 Default

`none`
18.113 fix nve/limit command

18.113.1 Syntax

```plaintext
fix ID group-ID nve/limit xmax
```

- ID, group-ID are documented in `fix` command
- nve = style name of this fix command
- xmax = maximum distance an atom can move in one timestep (distance units)

18.113.2 Examples

```plaintext
fix 1 all nve/limit 0.1
```

18.113.3 Description

Perform constant NVE updates of position and velocity for atoms in the group each timestep. A limit is imposed on the maximum distance an atom can move in one timestep. This is useful when starting a simulation with a configuration containing highly overlapped atoms. Normally this would generate huge forces which would blow atoms out of the simulation box, causing LAMMPS to stop with an error.

Using this fix can overcome that problem. Forces on atoms must still be computable (which typically means 2 atoms must have a separation distance > 0.0). But large velocities generated by large forces are reset to a value that corresponds to a displacement of length `xmax` in a single timestep. `Xmax` is specified in distance units; see the `units` command for details. The value of `xmax` should be consistent with the neighbor skin distance and the frequency of neighbor list re-building, so that pairwise interactions are not missed on successive timesteps as atoms move. See the `neighbor` and `neigh_modify` commands for details.

Note that if a velocity reset occurs the integrator will not conserve energy. On steps where no velocity resets occur, this integrator is exactly like the `fix nve` command. Since forces are unaltered, pressures computed by thermodynamic output will still be very large for overlapped configurations.

**Note:** You should not use `fix shake` in conjunction with this fix. That is because fix shake applies constraint forces based on the predicted positions of atoms after the next timestep. It has no way of knowing the timestep may change due to this fix, which will cause the constraint forces to be invalid. A better strategy is to turn off fix shake when performing initial dynamics that need this fix, then turn fix shake on when doing normal dynamics with a fixed-size timestep.

18.113.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix.

This fix computes a global scalar which can be accessed by various `output commands`. The scalar is the count of how many updates of atom’s velocity/position were limited by the maximum distance criterion. This should be roughly the number of atoms so affected, except that updates occur at both the beginning and end of a timestep in a velocity Verlet timestepping algorithm. This is a cumulative quantity for the current run, but is re-initialized to zero each time a run is performed. The scalar value calculated by this fix is “extensive”.

18.113. fix nve/limit command
No parameter of this fix can be used with the \textit{start/stop} keywords of the \textit{run} command. This fix is not invoked during \textit{energy minimization}.

- ID, group-ID are documented in fix command
- nve/manifold/rattle = style name of this fix command
- tol = tolerance to which Newton iteration must converge
- maxit = maximum number of iterations to perform
- manifold = name of the manifold
- manifold-args = parameters for the manifold
- one or more keyword/value pairs may be appended

  keyword = every
  every values = N
  N = print info about iteration every N steps. N = 0 means no output

18.115.2 Examples

- fix 1 all nve/manifold/rattle 1e-4 10 sphere 5.0
- fix step all nve/manifold/rattle 1e-8 100 ellipsoid 2.5 2.5 5.0 every 25
18.115.3 Description

Perform constant NVE integration to update position and velocity for atoms constrained to a curved surface (manifold) in the group each timestep. The constraint is handled by RATTLE (Andersen) written out for the special case of single-particle constraints as explained in (Paquay). V is volume; E is energy. This way, the dynamics of particles constrained to curved surfaces can be studied. If combined with fix langevin, this generates Brownian motion of particles constrained to a curved surface. For a list of currently supported manifolds and their parameters, see the Howto manifold doc page.

Note that the particles must initially be close to the manifold in question. If not, RATTLE will not be able to iterate until the constraint is satisfied, and an error is generated. For simple manifolds this can be achieved with region and create_atoms commands, but for more complex surfaces it might be more useful to write a script.

The manifold args may be equal-style variables, like so:

```
variable R equal "ramp(5.0,3.0)"
fix shrink_sphere all nve/manifold/rattle 1e-4 10 sphere v_R
```

In this case, the manifold parameter will change in time according to the variable. This is not a problem for the time integrator as long as the change of the manifold is slow with respect to the dynamics of the particles. Note that if the manifold has to exert work on the particles because of these changes, the total energy might not be conserved.

18.115.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

- nve/noforce = style name of this fix command

18.116.2 Examples

fix 3 wall nve/noforce

18.116.3 Description

Perform updates of position, but not velocity for atoms in the group each timestep. In other words, the force on the atoms is ignored and their velocity is not updated. The atom velocities are used to update their positions.

This can be useful for wall atoms, when you set their velocities, and want the wall to move (or stay stationary) in a prescribed fashion.

This can also be accomplished via the fix setforce command, but with fix nve/noforce, the forces on the wall atoms are unchanged, and can thus be printed by the dump command or queried with an equal-style variable that uses the fcm() group function to compute the total force on the group of atoms.

18.116.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.117 fix nve/sphere command

Accelerator Variants: nve/sphere/omp, nve/sphere/kk

18.117.1 Syntax

```
fix ID group-ID nve/sphere
```

- ID, group-ID are documented in fix command
- nve/sphere = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = update or disc
  - **update** value = dipole or dipole/dlm
  - dipole = update orientation of dipole moment during integration
  - dipole/dlm = use DLM integrator to update dipole orientation
  - disc value = none = treat particles as 2d discs, not spheres

18.117.2 Examples

```
fix 1 all nve/sphere
fix 1 all nve/sphere update dipole
fix 1 all nve/sphere disc
fix 1 all nve/sphere update dipole/dlm
```

18.117.3 Description

Perform constant NVE integration to update position, velocity, and angular velocity for finite-size spherical particles in the group each timestep. $V$ is volume; $E$ is energy. This creates a system trajectory consistent with the microcanonical ensemble.

This fix differs from the fix nve command, which assumes point particles and only updates their position and velocity. If the update keyword is used with the dipole value, then the orientation of the dipole moment of each particle is also updated during the time integration. This option should be used for models where a dipole moment is assigned to finite-size particles, e.g. spheroids via use of the atom_style hybrid sphere dipole command.

The default dipole orientation integrator can be changed to the Dullweber-Leimkuhler-McLachlan integration scheme (Dullweber) when using update with the value dipole/dlm. This integrator is symplectic and time-reversible, giving better energy conservation and allows slightly longer timesteps at only a small additional computational cost.

If the disc keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the dimension keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 18.117.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

### 18.117.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the `atom_style sphere` command. If the `dipole` keyword is used, then they must also store a dipole moment as defined by the `atom_style dipole` command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the `disc` keyword is only allowed for 2d simulations, as defined by the `dimension` keyword.

### 18.117.6 Related commands

`fix nve, fix nve/asphere`

### 18.117.7 Default

`none`

### 18.118 fix nve/spin command

#### 18.118.1 Syntax

```
fix ID group-ID nve/spin keyword values
```

- `ID, group-ID` are documented in `fix` command
- `nve/spin =` style name of this fix command

18.118.  fix nve/spin command
• keyword = `lattice`

  `lattice` value = `moving` or `frozen`
  - `moving` = integrate both spin and atomic degrees of freedom
  - `frozen` = integrate spins on a fixed lattice

### 18.118.2 Examples

```
fix 3 all nve/spin lattice moving
fix 1 all nve/spin lattice frozen
```

### 18.118.3 Description

Perform a symplectic integration for the spin or spin-lattice system.

The `lattice` keyword defines if the spins are integrated on a lattice of fixed atoms (`lattice = frozen`), or if atoms are moving (`lattice = moving`). The first case corresponds to a spin dynamics calculation, and the second to a spin-lattice calculation. By default a spin-lattice integration is performed (`lattice = moving`).

The `nve/spin` fix applies a Suzuki-Trotter decomposition to the equations of motion of the spin lattice system, following the scheme:

![Diagram](image)

according to the implementation reported in *(Omelyan)*.

A sectoring method enables this scheme for parallel calculations. The implementation of this sectoring algorithm is reported in *(Tranchida)*.
18.118.4 Restrictions

This fix style can only be used if LAMMPS was built with the SPIN package. See the Build package doc page for more info.

To use the spin algorithm, it is necessary to define a map with the atom_modify command. Typically, by adding the command:

```
atom_modify map array
```

before you create the simulation box. Note that the keyword “hash” instead of “array” is also valid.

none

18.120 fix nvk command

18.120.1 Syntax

fix ID group-ID nvk

• ID, group-ID are documented in fix command
• nvk = style name of this fix command

18.120.2 Examples

fix 1 all nvk

18.120.3 Description

Perform constant kinetic energy integration using the Gaussian thermostat to update position and velocity for atoms in the group each timestep. V is volume; K is kinetic energy. This creates a system trajectory consistent with the isokinetic ensemble.

The equations of motion used are those of Minary et al in (Minary), a variant of those initially given by Zhang in (Zhang).

The kinetic energy will be held constant at its value given when fix nvk is initiated. If a different kinetic energy is desired, the velocity command should be used to change the kinetic energy prior to this fix.
18.120.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.120.5 Restrictions

The Gaussian thermostat only works when it is applied to all atoms in the simulation box. Therefore, the group must be set to all.

This fix has not yet been implemented to work with the RESPA integrator.

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.120.6 Related commands

none

18.120.7 Default

none

18.121 fix nvt/asphere command

Accelerator Variants: nvt/asphere/omp

18.121.1 Syntax

fix ID group-ID nvt/asphere keyword value ...

- ID, group-ID are documented in fix command
- nvt/asphere = style name of this fix command
- additional thermostat related keyword/value pairs from the fix nvt command can be appended
18.121.2 Examples

```
fix 1 all nvt/asphere temp 300.0 300.0 100.0
fix 1 all nvt/asphere temp 300.0 300.0 100.0 drag 0.2
```

18.121.3 Description

Perform constant NVT integration to update position, velocity, orientation, and angular velocity each timestep for aspherical or ellipsoidal particles in the group using a Nose/Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

This fix differs from the `fix nvt` command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the aspherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

Additional parameters affecting the thermostat are specified by keywords and values documented with the `fix nvt` command. See, for example, discussion of the `temp` and `drag` keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/asphere”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp/asphere
```

See the `compute temp/asphere` command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp`. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the `compute_modify` command or print this temperature during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with `compute commands` that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.
18.121.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used in its thermostatting procedure.

The fix_modify energy option is supported by this fix to add the energy change induced by Nose/Hoover thermostatting to the system’s potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the fix nvt command.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

18.121.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style ellipsoid command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

18.121.6 Related commands

fix nvt, fix nve_asphere, fix npt_asphere, fix_modify

18.122 fix nvt/body command

18.122.1 Syntax

```
fix ID group-ID nvt/body keyword value ...
```

- ID, group-ID are documented in fix command
- nvt/body = style name of this fix command
- additional thermostat related keyword/value pairs from the fix nvt command can be appended
18.122.2 Examples

```
fix 1 all nvt/body temp 300.0 300.0 100.0
fix 1 all nvt/body temp 300.0 300.0 100.0 drag 0.2
```

18.122.3 Description

Perform constant NVT integration to update position, velocity, orientation, and angular velocity each timestep for body particles in the group using a Nose/Hoover temperature thermostat. $V$ is volume; $T$ is temperature. This creates a system trajectory consistent with the canonical ensemble.

This fix differs from the `fix nvt` command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the body particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

Additional parameters affecting the thermostat are specified by keywords and values documented with the `fix nvt` command. See, for example, discussion of the `temp` and `drag` keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/body”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp/body
```

See the `compute temp/body` command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp`. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the `compute_modify` command or print this temperature during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with `compute commands` that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.
18.122.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used in its thermostating procedure.

The fix_modify energy option is supported by this fix to add the energy change induced by Nose/Hoover thermostating to the system’s potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the fix nvt command.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

18.122.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style body command.

18.122.6 Related commands

fix nvt, fix nve_body, fix npt_body, fix_modify

18.122.7 Default

18.123 fix nvt/manifold/rattle command

18.123.1 Syntax

fix ID group-ID nvt/manifold/rattle tol maxit manifold manifold-args keyword value ...

• ID, group-ID are documented in fix command
• nvt/manifold/rattle = style name of this fix command
• tol = tolerance to which Newton iteration must converge
• maxit = maximum number of iterations to perform
• manifold = name of the manifold
• manifold-args = parameters for the manifold
• one or more keyword/value pairs may be appended
keyword = temp or tchain or every
temp values = Tstart Tstop Tdamp
    Tstart, Tstop = external temperature at start/end of run
    Tdamp = temperature damping parameter (time units)
tchain value = N
    N = length of thermostat chain (1 = single thermostat)
every value = N
    N = print info about iteration every N steps. N = 0 means no output

18.123.2 Examples

fix 1 all nvt/manifold/rattle 1e-4 10 cylinder 3.0 temp 1.0 1.0 10.0

18.123.3 Description

This fix combines the RATTLE-based (Andersen) time integrator of fix nve/manifold/rattle (Paquay) with a Nose-Hoover-chain thermostat to sample the canonical ensemble of particles constrained to a curved surface (manifold). This sampling does suffer from discretization bias of O(dt). For a list of currently supported manifolds and their parameters, see the Howto manifold doc page.

18.123.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.123.5 Restrictions

This fix is part of the USER-MANIFOLD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

fix nve/manifold/rattle, fix manifoldforce Default: every = 0

18.124 fix nvt/sllod command

Accelerator Variants: nvt/sllod/intel, nvt/sllod/omp

18.124.1 Syntax

fix ID group-ID nvt/sllod keyword value ...

- ID, group-ID are documented in fix command
- nvt/sllod = style name of this fix command
- additional thermostat related keyword/value pairs from the fix nvt command can be appended

18.124.2 Examples

```plaintext
fix 1 all nvt/sllod temp 300.0 300.0 100.0
fix 1 all nvt/sllod temp 300.0 300.0 100.0 drag 0.2
```

18.124.3 Description

Perform constant NVT integration to update positions and velocities each timestep for atoms in the group using a Nose/Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

This thermostat is used for a simulation box that is changing size and/or shape, for example in a non-equilibrium MD (NEMD) simulation. The size/shape change is induced by use of the fix deform command, so each point in the simulation box can be thought of as having a “streaming” velocity. This position-dependent streaming velocity is subtracted from each atom’s actual velocity to yield a thermal velocity which is used for temperature computation and thermostatting. For example, if the box is being sheared in x, relative to y, then points at the bottom of the box (low y) have a small x velocity, while points at the top of the box (hi y) have a large x velocity. These velocities do not contribute to the thermal “temperature” of the atom.

**Note:** Fix deform has an option for remapping either atom coordinates or velocities to the changing simulation box. To use fix nvt/sllod, fix deform should NOT remap atom positions, because fix nvt/sllod adjusts the atom positions and velocities to create a velocity profile that matches the changing box size/shape. Fix deform SHOULD remap atom velocities when atoms cross periodic boundaries since that is consistent with maintaining the velocity profile created by fix nvt/sllod. LAMMPS will give an error if this setting is not consistent.

The SLLOD equations of motion, originally proposed by Hoover and Ladd (see (Evans and Morriss)), were proven to be equivalent to Newton’s equations of motion for shear flow by (Evans and Morriss). They were later shown to generate the desired velocity gradient and the correct production of work by stresses for all forms of homogeneous flow by (Daivis and Todd). As implemented in LAMMPS, they are coupled to a Nose/Hoover chain thermostat in a velocity Verlet formulation, closely following the implementation used for the fix nvt command.

**Note:** A recent (2017) book by (Daivis and Todd) discusses use of the SLLOD method and non-equilibrium MD (NEMD) thermostatting generally, for both simple and complex fluids, e.g. molecular systems. The latter can be tricky to do correctly.
Additional parameters affecting the thermostat are specified by keywords and values documented with the fix nvt command. See, for example, discussion of the temp and drag keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/deform”, as if this command had been issued:

```plaintext
compute fix-ID_temp group-ID temp/deform
```

See the compute temp/deform command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the thermo_style command) with ID = thermo_temp. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the compute_modify command or print this temperature during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with compute commands that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the fix_modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute commands to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 18.124.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used in its thermostatting procedure.

The fix_modify energy option is supported by this fix to add the energy change induced by Nose/Hoover thermostatting to the system’s potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the fix nvt command.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.
18.124.5 Restrictions

This fix works best without Nose-Hoover chain thermostats, i.e. using tchain = 1. Setting tchain to larger values can result in poor equilibration.

18.124.6 Related commands

fix nve, fix nvt, fix temp/rescale, fix langevin, fix_modify, compute temp/deform

• additional thermostat related keyword/value pairs from the fix nvt/eff command can be appended

18.125.2 Examples

fix 1 all nvt/sllod/eff temp 300.0 300.0 0.1
fix 1 all nvt/sllod/eff temp 300.0 300.0 0.1 drag 0.2

18.125.3 Description

Perform constant NVT integration to update positions and velocities each timestep for nuclei and electrons in the group for the electron force field model, using a Nose/Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

The operation of this fix is exactly like that described by the fix nvt/sllod command, except that the radius and radial velocity of electrons are also updated and thermostatted. Likewise the temperature calculated by the fix, using the compute it creates (as discussed in the fix nvt, npt, and nph doc page), is performed with a compute temp/deform/eff command that includes the eFF contribution to the temperature from the electron radial velocity.
18.125.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used in its thermostatting procedure.

The fix_modify energy option is supported by this fix to add the energy change induced by Nose/Hoover thermostatting to the system’s potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the fix nvt/eff command.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

18.125.5 Restrictions

This fix is part of the USER-EFF package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix works best without Nose-Hoover chain thermostats, i.e. using tchain = 1. Setting tchain to larger values can result in poor equilibration.

<td>nvt/sphere temp 300.0 300.0 100.0 disc</td>
</tr>
<tr>
<td>fix</td>
<td>all</td>
<td>nvt/sphere temp 300.0 300.0 100.0 drag 0.2</td>
</tr>
</tbody>
</table>

18.126.3 Description

Perform constant NVT integration to update position, velocity, and angular velocity each timestep for finite-size spherical particles in the group using a Nose/Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

This fix differs from the fix nvt command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the spherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

If the disc keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the dimension keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

Additional parameters affecting the thermostat are specified by keywords and values documented with the fix nvt command. See, for example, discussion of the temp and drag keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/sphere”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp/sphere
```

See the compute temp/sphere command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the thermo_style command) with ID = thermo_temp. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the compute_modify command or print this temperature during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with compute commands that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the fix_modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute commands to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 18.126.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used in its thermostatting procedure.

The fix_modify energy option is supported by this fix to add the energy change induced by Nose/Hoover thermostatting to the system's potential energy as part of thermodynamic output.

This fix computes the same global scalar and global vector of quantities as does the fix nvt command.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

### 18.126.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the atom_style sphere command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the disc keyword is only allowed for 2d simulations, as defined by the dimension keyword.

```

- ID, group-ID are documented in fix command
- oneway = style name of this fix command
- N = apply this fix every this many timesteps
- region-ID = ID of region where fix is active
- direction = x or -x or y or -y or z or -z = coordinate and direction of the oneway constraint

18.127.2 Examples

```
fix ions oneway 10 semi -x
fix all oneway 1 left -z
fix all oneway 1 right z
```

18.127.3 Description

Enforce that particles in the group and in a given region can only move in one direction. This is done by reversing a particle’s velocity component, if it has the wrong sign in the specified dimension. The effect is that the particle moves in one direction only.

This can be used, for example, as a simple model of a semi-permeable membrane, or as an implementation of Maxwell’s demon.

18.127.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

fix gb all orient/bcc 0 1 2.882 0.001 0.25 0.75 ngb.left ngb.right
```

18.129.3 Description

The fix applies an orientation-dependent force to atoms near a planar grain boundary which can be used to induce grain boundary migration (in the direction perpendicular to the grain boundary plane). The motivation and explanation of this force and its application are described in *(Janssens)*. The adaptation to bcc crystals is described in *(Wicaksono1)*. The computed force is only applied to atoms in the fix group.

The basic idea is that atoms in one grain (on one side of the boundary) have a potential energy dE added to them. Atoms in the other grain have 0.0 potential energy added. Atoms near the boundary (whose neighbor environment is intermediate between the two grain orientations) have an energy between 0.0 and dE added. This creates an effective driving force to reduce the potential energy of atoms near the boundary by pushing them towards one of the grain orientations. For dir = 1 and dE > 0, the boundary will thus move so that the grain described by file0 grows and the grain described by file1 shrinks. Thus this fix is designed for simulations of two-grain systems, either with one grain boundary and free surfaces parallel to the boundary, or a system with periodic boundary conditions and two equal and
opposite grain boundaries. In either case, the entire system can displace during the simulation, and such motion should be accounted for in measuring the grain boundary velocity.

The potential energy added to atom I is given by these formulas

\[ \xi_i = \sum_{j=1}^{12} |r_{ij} - r_i^j| \]  

(1)

\[ \xi_{IJ} = \sum_{j=1}^{12} |r_{ij}^j - r_i^j| \]  

(2)

\[ \xi_{low} = \text{cutlo} \xi_{IJ} \]  

(3)

\[ \xi_{high} = \text{cuthi} \xi_{IJ} \]  

(4)

\[ \omega_i = \frac{\pi}{2} \frac{\xi_i - \xi_{low}}{\xi_{high} - \xi_{low}} \]  

(5)

\[ u_i = \begin{cases} 0 & \text{for } \xi_i < \xi_{low} \\
= dE \frac{1 - \cos(2\omega_i)}{2} & \text{for } \xi_{low} < \xi_i < \xi_{high} \\
= dE & \text{for } \xi_{high} < \xi_i \end{cases} \]  

(6)

which are fully explained in (Janssens). For fcc crystals this order parameter Xi for atom I in equation (1) is a sum over the 12 nearest neighbors of atom I. For bcc crystals it is the corresponding sum of the 8 nearest neighbors. Rj is the vector from atom I to its neighbor J, and RIj is a vector in the reference (perfect) crystal. That is, if dir = 0/1, then RIj is a vector to an atom coord from file 0/1. Equation (2) gives the expected value of the order parameter XiIJ in the other grain. Hi and lo cutoffs are defined in equations (3) and (4), using the input parameters cutlo and cuthi as thresholds to avoid adding grain boundary energy when the deviation in the order parameter from 0 or 1 is small (e.g. due to thermal fluctuations in a perfect crystal). The added potential energy Ui for atom I is given in equation (6) where it is interpolated between 0 and dE using the two threshold Xi values and the Wi value of equation (5).

The derivative of this energy expression gives the force on each atom which thus depends on the orientation of its neighbors relative to the 2 grain orientations. Only atoms near the grain boundary feel a net force which tends to drive them to one of the two grain orientations.

In equation (1), the reference vector used for each neighbor is the reference vector closest to the actual neighbor position. This means it is possible two different neighbors will use the same reference vector. In such cases, the atom in question is far from a perfect orientation and will likely receive the full dE addition, so the effect of duplicate reference vector usage is small.

The dir parameter determines which grain wants to grow at the expense of the other. A value of 0 means the first grain will shrink; a value of 1 means it will grow. This assumes that dE is positive. The reverse will be true if dE is negative.

The alat parameter is the cubic lattice constant for the fcc or bcc material and is only used to compute a cutoff distance of 1.57 * alat / sqrt(2) for finding the 12 or 8 nearest neighbors of each atom (which should be valid for an fcc or bcc crystal). A longer/shorter cutoff can be imposed by adjusting alat. If a particular atom has less than 12 or 8 neighbors within the cutoff, the order parameter of equation (1) is effectively multiplied by 12 or 8 divided by the actual number of neighbors within the cutoff.

The dE parameter is the maximum amount of additional energy added to each atom in the grain which wants to shrink.

The cutlo and cuthi parameters are used to reduce the force added to bulk atoms in each grain far away from the boundary. An atom in the bulk surrounded by neighbors at the ideal grain orientation would compute an order parameter of 0 or 1 and have no force added. However, thermal vibrations in the solid will cause the order parameters to be
greater than 0 or less than 1. The cutoff parameters mask this effect, allowing forces to only be added to atoms with order-parameters between the cutoff values.

File0 and file1 are filenames for the two grains which each contain 6 vectors (6 lines with 3 values per line) which specify the grain orientations. Each vector is a displacement from a central atom (0,0,0) to a nearest neighbor atom in an fcc lattice at the proper orientation. The vector lengths should all be identical since an fcc lattice has a coordination number of 12. Only 6 are listed due to symmetry, so the list must include one from each pair of equal-and-opposite neighbors. A pair of orientation files for a Sigma=5 tilt boundary are shown below. A tutorial that can help for writing the orientation files is given in (Wicaksono2)

18.129.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the potential energy of atom interactions with the grain boundary driving force to the system’s potential energy as part of thermodynamic output.

The fix_modify respa option is supported by these fixes. This allows to set at which level of the r-RESPA integrator a fix is adding its forces. Default is the outermost level.

This fix calculates a global scalar which can be accessed by various output commands. The scalar is the potential energy change due to this fix. The scalar value calculated by this fix is “extensive”.

This fix also calculates a per-atom array which can be accessed by various output commands. The array stores the order parameter Xi and normalized order parameter (0 to 1) for each atom. The per-atom values can be accessed on any timestep.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.129.5 Restrictions

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix should only be used with fcc or bcc lattices.

18.130 fix orient/eco command

```plaintext
fix ID group-ID orient/eco u0 eta cutoff orientationsFile
```

- ID, group-ID are documented in fix command
- u0 = energy added to each atom (energy units)
- eta = cutoff value (usually 0.25)
- cutoff = cutoff radius for orientation parameter calculation
- orientationsFile = file that specifies orientation of each grain

18.130.1 Examples

```plaintext
fix gb all orient/eco 0.08 0.25 3.524 sigma5.ori
```

18.130.2 Description

The fix applies a synthetic driving force to a grain boundary which can be used for the investigation of grain boundary motion. The affiliation of atoms to either of the two grains forming the grain boundary is determined from an orientation-dependent order parameter as described in (Ulomek). The potential energy of atoms is either increased by an amount of 0.5*\(u0\) or -0.5*\(u0\) according to the orientation of the surrounding crystal. This creates a potential energy gradient which pushes atoms near the grain boundary to orient according to the energetically favorable grain orientation. This fix is designed for applications in bicrystal system with one grain boundary and open ends, or two opposite grain boundaries in a periodic system. In either case, the entire system can experience a displacement during the simulation which needs to be accounted for in the evaluation of the grain boundary velocity. While the basic method is described in (Ulomek), the implementation follows the efficient implementation from (Schratt & Mohles).
The synthetic potential energy added to an atom $j$ is given by the following formulas

$$w(|\vec{r}_{jk}|) = w_{jk} = \begin{cases} \frac{|\vec{r}_{jk}|^4}{r_{cut}^4} - 2 \frac{|\vec{r}_{jk}|^2}{r_{cut}^2} + 1, & |\vec{r}_{jk}| < r_{cut} \\ 0, & |\vec{r}_{jk}| \geq r_{cut} \end{cases}$$

$$\chi_j = \frac{1}{N} \sum_{l=1}^{3} \left[ |\psi^I_l(\vec{r}_{j})|^2 - |\psi^{II}_l(\vec{r}_{j})|^2 \right]$$

$$\psi^X_l(\vec{r}_{j}) = \sum_{k \in \Gamma_j} w_{jk} \exp \left( i \vec{r}_{jk} \cdot \vec{q}^X_l \right)$$

$$u(\chi_j) = \frac{u_0}{2} \begin{cases} 1, & \chi_j \geq \eta \\ \sin \left( \frac{\pi \chi_j}{2\eta} \right), & -\eta < \chi_j < \eta \\ -1, & \chi_j \leq -\eta \end{cases}$$

which are fully explained in (Ulomek) and (Schratt & Mohles).

The force on each atom is the negative gradient of the synthetic potential energy. It depends on the surrounding of this atom. An atom far from the grain boundary does not experience a synthetic force as its surrounding is that of an oriented single crystal and thermal fluctuations are masked by the parameter $\eta$. Near the grain boundary however, the gradient is nonzero and synthetic force terms are computed. The orientationsFile specifies the perfect oriented crystal basis vectors for the two adjoining crystals. The first three lines (line=row vector) for the energetically penalized and the last three lines for the energetically favored grain assuming $u_0$ is positive. For negative $u_0$, this is reversed. With the cutoff parameter, the size of the region around each atom which is used in the order parameter computation is defined. The cutoff must be smaller than the interaction range of the MD potential. It should at least include the nearest neighbor shell. For high temperatures or low angle grain boundaries, it might be beneficial to increase the cutoff in order to get a more precise identification of the atoms surrounding. However, computation time will increase as more atoms are considered in the order parameter and force computation. It is also worth noting that the cutoff radius must not exceed the communication distance for ghost atoms in LAMMPS. With orientationsFile, the 6 oriented crystal basis vectors is specified. Each line of the input file contains the three components of a primitive lattice vector oriented according to the grain orientation in the simulation box. The first (last) three lines correspond to the primitive lattice vectors of the first (second) grain. An example for a $\Sigma(001)$ mis-orientation is given at the end.

If no synthetic energy difference between the grains is created, $u_0 = 0$, the force computation is omitted. In this case, still, the order parameter of the driving force is computed and can be used to track the grain boundary motion throughout the simulation.

### 18.130.3 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to :doc: binary restart files. The fix_modify energy option is supported by this fix to add the potential energy of atom interactions with the grain boundary driving force to the system’s potential energy as part of thermodynamic output. The total sum of added synthetic potential energy is computed and can be accessed by various output options. The order parameter as well as the thermally masked output parameter are stored in per-atom arrays and can also be accessed by various output commands.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
18.130.4 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.131 fix pafi command

18.131.1 Syntax

```
fix ID group-ID pafi compute-ID Temp Tdamp seed keyword values...
```

- ID, group-ID are documented in fix command
- pafi = style name of this fix command
- compute-ID = ID of a compute property/atom that holds data used by this fix
- Temp = desired temperature (temperature units)
- Tdamp = damping parameter (time units)
- seed = random number seed to use for white noise (positive integer)
- keyword = overdamped or com
overdamped value = yes or no or 1 or 0
yes or 1 = Brownian (overdamped) integration in hyperplane
no or 0 = Langevin integration in hyperplane
com value = yes or no or 1 or 0
yes or 1 = zero linear momentum, fixing center of mass (recommended)
no or 0 = do not zero linear momentum, allowing center of mass drift

18.131.2 Examples

```plaintext
compute pa all property/atom d_nx d_ny d_nz d_dnx d_dny d_ddnz
run 0 post no
fix hp all pafi pa 500.0 0.01 434 overdamped yes
```

18.131.3 Description

Perform Brownian or Langevin integration whilst constraining the system to lie in some hyperplane, which is expected to be the tangent plane to some reference pathway in a solid state system. The instantaneous value of a modified force projection is also calculated, whose time integral can be shown to be equal to the true free energy gradient along the minimum free energy path local to the reference pathway. A detailed discussion of the projection technique can be found in (Swinburne).

This fix can be used with LAMMPS as demonstrated in examples/USER/misc/pafi, though it is primarily intended to be coupled with the PAFI C++ code, developed at https://github.com/tomswinburne/pafi, which distributes multiple LAMMPS workers in parallel to compute and collate hyperplane-constrained averages, allowing the calculation of free energy barriers and pathways.

A `compute property/atom` must be provided with 9 fields per atom coordinate, which in order are the x,y,z coordinates of a configuration on the reference path, the x,y,z coordinates of the path tangent (derivative of path position with path coordinate) and the x,y,z coordinates of the change in tangent (derivative of path tangent with path coordinate).

A 4-element vector is also calculated by this fix. The 4 components are the modified projected force, its square, the expected projection of the minimum free energy path tangent on the reference path tangent and the minimum image distance between the current configuration and the reference configuration, projected along the path tangent. This latter value should be essentially zero.

**Note:** When com=yes/1, which is recommended, the provided tangent vector must also have zero center of mass. This can be achieved by subtracting from each coordinate of the path tangent the average x,y,z value. The PAFI C++ code (see above) can generate these paths for use in LAMMPS.

**Note:** When overdamped=yes/1, the Tdamp parameter should be around 5-10 times smaller than that used in typical Langevin integration. See `fix langevin` for typical values.
18.131.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix produces a global vector each timestep which can be accessed by various output commands.

18.131.5 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.131.6 Default

The option defaults are com = yes, overdamped = no

```

18.132.3 Description

Calculate the dynamical matrix from molecular dynamics simulations based on fluctuation-dissipation theory for a group of atoms.

Consider a crystal with \( N \) unit cells in three dimensions labeled \( l = (l_1, l_2, l_3) \) where \( l_i \) are integers. Each unit cell is defined by three linearly independent vectors \( \mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3 \) forming a parallelepiped, containing \( K \) basis atoms labeled \( k \).

Based on fluctuation-dissipation theory, the force constant coefficients of the system in reciprocal space are given by (Campana, Kong)

\[
\Phi_{\alpha k, \beta k'}(\mathbf{q}) = k_B T \mathbf{G}^{-1}_{\alpha k, \beta k'}(\mathbf{q})
\]

where \( \mathbf{G} \) is the Green’s functions coefficients given by

\[
\mathbf{G}_{\alpha k, \beta k'}(\mathbf{q}) = \langle \mathbf{u}_{\alpha k}(\mathbf{q}) \cdot \mathbf{u}^*_{\beta k'}(\mathbf{q}) \rangle
\]

where \( \langle \ldots \rangle \) denotes the ensemble average, and

\[
\mathbf{u}_{\alpha k}(\mathbf{q}) = \sum_l \mathbf{u}_{l\alpha k} \exp(i\mathbf{q}\mathbf{r}_l)
\]

is the \( \alpha \) component of the atomic displacement for the \( k \)th atom in the unit cell in reciprocal space at \( \mathbf{q} \). In practice, the Green’s functions coefficients can also be measured according to the following formula,

\[
\mathbf{G}_{\alpha k, \beta k'}(\mathbf{q}) = \langle \mathbf{R}_{\alpha k}(\mathbf{q}) \cdot \mathbf{R}^*_{\beta k'}(\mathbf{q}) \rangle - \langle \mathbf{R}_{\alpha k}(\mathbf{q}) \rangle \cdot \langle \mathbf{R}^*_{\beta k'}(\mathbf{q}) \rangle
\]

where \( \mathbf{R} \) is the instantaneous positions of atoms, and \( \langle \mathbf{R} \rangle \) is the averaged atomic positions. It gives essentially the same results as the displacement method and is easier to implement in an MD code.

Once the force constant matrix is known, the dynamical matrix \( \mathbf{D} \) can then be obtained by

\[
\mathbf{D}_{\alpha k, \beta k'}(\mathbf{q}) = (m_k m_{k'})^{-\frac{1}{2}} \Phi_{\alpha k, \beta k'}(\mathbf{q})
\]

whose eigenvalues are exactly the phonon frequencies at \( \mathbf{q} \).

This fix uses positions of atoms in the specified group and calculates two-point correlations. To achieve this, the positions of the atoms are examined every \( Nevery \) steps and are Fourier-transformed into reciprocal space, where the averaging process and correlation computation is then done. After every \( Noutput \) measurements, the matrix \( \mathbf{G}(\mathbf{q}) \) is calculated and inverted to obtain the elastic stiffness coefficients. The dynamical matrices are then constructed and written to \( \text{prefix}.bin.timestep \) files in binary format and to the file \( \text{prefix}.log \) for each wave-vector \( \mathbf{q} \).

A detailed description of this method can be found in (Kong2011).

The \( \text{sysdim} \) keyword is optional. If specified with a value smaller than the dimensionality of the LAMMPS simulation, its value is used for the dynamical matrix calculation. For example, using LAMMPS ot model a 2D or 3D system, the phonon dispersion of a 1D atomic chain can be computed using \( \text{sysdim} = 1 \).

The \( \text{nasr} \) keyword is optional. An iterative procedure is employed to enforce the acoustic sum rule on \( \Phi \) at \( \Gamma \), and the number provided by keyword \( \text{nasr} \) gives the total number of iterations. For a system whose unit cell has only one atom, \( \text{nasr} = 1 \) is sufficient; for other systems, \( \text{nasr} = 10 \) is typically sufficient.
The \textit{map\_file} contains the mapping information between the lattice indices and the atom IDs, which tells the code which atom sits at which lattice point; the lattice indices start from 0. An auxiliary code, \texttt{latgen}, can be employed to generate the compatible map file for various crystals.

In case one simulates a non-periodic system, where the whole simulation box is treated as a unit cell, one can set \textit{map\_file} as \texttt{GAMMA}, so that the mapping info will be generated internally and a file is not needed. In this case, the dynamical matrix at only the gamma-point will/can be evaluated. Please keep in mind that \texttt{fix-phonon} is designed for crystals, it will be inefficient and even degrade the performance of lammps in case the unit cell is too large.

The calculated dynamical matrix elements are written out in $\text{energy/distance}^2/\text{mass}$ units. The coordinates for $q$ points in the log file is in the units of the basis vectors of the corresponding reciprocal lattice.

**18.132.4 Restart, fix\_modify, output, run start/stop, minimize info**

No information about this fix is written to \textit{binary restart files}.

The \texttt{fix\_modify temp} option is supported by this fix. You can use it to change the temperature compute from \texttt{thermo\_temp} to the one that reflects the true temperature of atoms in the group.

No global scalar or vector or per-atom quantities are stored by this fix for access by various \textit{output commands}.

Instead, this fix outputs its initialization information (including mapping information) and the calculated dynamical matrices to the file \texttt{prefix.log}, with the specified \texttt{prefix}. The dynamical matrices are also written to files \texttt{prefix.bin.timestep} in binary format. These can be read by the post-processing tool in \texttt{tools/phonon} to compute the phonon density of states and/or phonon dispersion curves.

No parameter of this fix can be used with the \texttt{start/stop} keywords of the \texttt{run} command.

This fix is not invoked during \textit{energy minimization}.

**18.132.5 Restrictions**

This fix assumes a crystalline system with periodical lattice. The temperature of the system should not exceed the melting temperature to keep the system in its solid state.

This fix is part of the USER-PHONON package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

This fix requires LAMMPS be built with an FFT library. See the \textit{Build settings} doc page for details.

**18.132.6 Related commands**

\texttt{compute msd, dynamical\_matrix}

**18.132.7 Default**

The option defaults are \texttt{sysdim = the same dimension as specified by the dimension command}, and \texttt{nasr = 20}.

18.133 fix pimd command

18.133.1 Syntax

```
fix ID group-ID pimd keyword value ...
```

- ID, group-ID are documented in fix command
- pimd = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = method or fmass or sp or temp or nhc
  - method value = pimd or nmpimd or cmd
  - fmass value = scaling factor on mass
  - sp value = scaling factor on Planck constant
  - temp value = temperature (temperarate units)
  - nhc value = Nc = number of chains in Nose-Hoover thermostat

18.133.2 Examples

```
fix 1 all pimd method nmpimd fmass 1.0 sp 2.0 temp 300.0 nhc 4
```

18.133.3 Description

This command performs quantum molecular dynamics simulations based on the Feynman path integral to include effects of tunneling and zero-point motion. In this formalism, the isomorphism of a quantum partition function for the original system to a classical partition function for a ring-polymer system is exploited, to efficiently sample configurations from the canonical ensemble (Feynman). The classical partition function and its components are given by the following equations:

\[
Z = \int dq dp \cdot \exp[-\beta H_{eff}]
\]

\[
H_{eff} = \left( \sum_{i=1}^{P} \frac{p_i^2}{2m_i} \right) + V_{eff}
\]

\[
V_{eff} = \sum_{i=1}^{P} \left[ \frac{m_P}{2\beta^2\hbar^2} (q_i - q_{i+1})^2 + \frac{1}{P} V(q_i) \right]
\]

The interested user is referred to any of the numerous references on this methodology, but briefly, each quantum particle in a path integral simulation is represented by a ring-polymer of P quasi-beads, labeled from 1 to P. During the simulation, each quasi-bead interacts with beads on the other ring-polymers with the same imaginary time index (the second term in the effective potential above). The quasi-beads also interact with the two neighboring quasi-beads through the spring potential in imaginary-time space (first term in effective potential). To sample the canonical ensemble, a Nose-Hoover massive chain thermostat is applied (Tuckerman). With the massive chain algorithm, a
A chain of NH thermostats is coupled to each degree of freedom for each quasi-bead. The keyword `temp` sets the target temperature for the system and the keyword `nhc` sets the number $N_c$ of thermostats in each chain. For example, for a simulation of $N$ particles with $P$ beads in each ring-polymer, the total number of NH thermostats would be $3 \times N \times P \times N_c$.

**Note:** This fix implements a complete velocity-verlet integrator combined with NH massive chain thermostat, so no other time integration fix should be used.

The `method` keyword determines what style of PIMD is performed. A value of `pimd` is standard PIMD. A value of `nmpimd` is for normal-mode PIMD. A value of `cmd` is for centroid molecular dynamics (CMD). The difference between the styles is as follows.

In standard PIMD, the value used for a bead’s fictitious mass is arbitrary. A common choice is to use $M_i = m/P$, which results in the mass of the entire ring-polymer being equal to the real quantum particle. But it can be difficult to efficiently integrate the equations of motion for the stiff harmonic interactions in the ring polymers.

A useful way to resolve this issue is to integrate the equations of motion in a normal mode representation, using Normal Mode Path-Integral Molecular Dynamics (NMPIMD) (Cao1). In NMPIMD, the NH chains are attached to each normal mode of the ring-polymer and the fictitious mass of each mode is chosen as $M_k = \text{the eigenvalue of the } k\text{th normal mode for } k > 0$. The $k = 0$ mode, referred to as the zero-frequency mode or centroid, corresponds to overall translation of the ring-polymer and is assigned the mass of the real particle.

Motion of the centroid can be effectively uncoupled from the other normal modes by scaling the fictitious masses to achieve a partial adiabatic separation. This is called a Centroid Molecular Dynamics (CMD) approximation (Cao2). The time-evolution (and resulting dynamics) of the quantum particles can be used to obtain centroid time correlation functions, which can be further used to obtain the true quantum correlation function for the original system. The CMD method also uses normal modes to evolve the system, except only the $k > 0$ modes are thermostatted, not the centroid degrees of freedom.

The keyword `fmass` sets a further scaling factor for the fictitious masses of beads, which can be used for the Partial Adiabatic CMD (Hone), or to be set as $P$, which results in the fictitious masses to be equal to the real particle masses.

The keyword `sp` is a scaling factor on Planck’s constant, which can be useful for debugging or other purposes. The default value of 1.0 is appropriate for most situations.

The PIMD algorithm in LAMMPS is implemented as a hyper-parallel scheme as described in (Calhoun). In LAMMPS this is done by using `multi-replica feature` in LAMMPS, where each quasi-particle system is stored and simulated on a separate partition of processors. The following diagram illustrates this approach. The original system with 2 ring polymers is shown in red. Since each ring has 4 quasi-beads (imaginary time slices), there are 4 replicas of the system, each running on one of the 4 partitions of processors. Each replica (shown in green) owns one quasi-bead in each ring.
To run a PIMD simulation with M quasi-beads in each ring polymer using N MPI tasks for each partition’s domain-decomposition, you would use $P = MXN$ processors (cores) and run the simulation as follows:

```
mpirun -np P lmp_mpi -partition MxN -in script
```

Note that in the LAMMPS input script for a multi-partition simulation, it is often very useful to define a *uloop-style variable* such as

```
variable ibead uloop M pad
```

where $M$ is the number of quasi-beads (partitions) used in the calculation. The uloop variable can then be used to manage I/O related tasks for each of the partitions, e.g.

```
dump dcd all dcd 10 system_${ibead}.dcd
restart 1000 system_${ibead}.restart1 system_${ibead}.restart2
read_restart system_${ibead}.restart2
```
18.133.4 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

A PIMD simulation can be initialized with a single data file read via the read_data command. However, this means all quasi-beads in a ring polymer will have identical positions and velocities, resulting in identical trajectories for all quasi-beads. To avoid this, users can simply initialize velocities with different random number seeds assigned to each partition, as defined by the uloop variable, e.g.

```
velocity all create 300.0 1234{ibead} rot yes dist gaussian
```

18.133.5 Default

The keyword defaults are method = pimd, fmass = 1.0, sp = 1.0, temp = 300.0, and nhc = 2.

18.135 fix plumed command

18.135.1 Syntax

```
fix ID group-ID plumed keyword value ...
```

- ID, group-ID are documented in fix command
- plumed = style name of this fix command
- keyword = plumedfile or outfile
  - `plumedfile arg` = name of PLUMED input file to use (default: NULL)
  - `outfile arg` = name of file on which to write the PLUMED log (default: NULL)
18.135.2 Examples

```plaintext
fix pl all plumed all plumed plumedfile plumed.dat outfile p.log
```

18.135.3 Description

This fix instructs LAMMPS to call the PLUMED library, which allows one to perform various forms of trajectory analysis on the fly and to also use methods such as umbrella sampling and metadynamics to enhance the sampling of phase space.

The documentation included here only describes the fix plumed command itself. This command is LAMMPS specific, whereas most of the functionality implemented in PLUMED will work with a range of MD codes, and when PLUMED is used as a stand alone code for analysis. The full documentation for PLUMED is available online and included in the PLUMED source code. The PLUMED library development is hosted at https://github.com/plumed/plumed2 A detailed discussion of the code can be found in (PLUMED).

There is an example input for using this package with LAMMPS in the examples/USER/plumed directory.

The command to make LAMMPS call PLUMED during a run requires two keyword value pairs pointing to the PLUMED input file and an output file for the PLUMED log. The user must specify these arguments every time PLUMED is to be used. Furthermore, the fix plumed command should appear in the LAMMPS input file after relevant input parameters (e.g. the timestep) have been set.

The `group-ID` entry is ignored. LAMMPS will always pass all the atoms to PLUMED and there can only be one instance of the plumed fix at a time. The way the plumed fix is implemented ensures that the minimum amount of information required is communicated. Furthermore, PLUMED supports multiple, completely independent collective variables, multiple independent biases and multiple independent forms of analysis. There is thus really no restriction in functionality by only allowing only one plumed fix in the LAMMPS input.

The `plumedfile` keyword allows the user to specify the name of the PLUMED input file. Instructions as to what should be included in a plumed input file can be found in the documentation for PLUMED.

The `outfile` keyword allows the user to specify the name of a file in which to output the PLUMED log. This log file normally just repeats the information that is contained in the input file to confirm it was correctly read and parsed. The names of the files in which the results are stored from the various analysis options performed by PLUMED will be specified by the user in the PLUMED input file.

18.135.4 Restart, fix_modify, output, run start/stop, minimize info

When performing a restart of a calculation that involves PLUMED you must include a RESTART command in the PLUMED input file as detailed in the PLUMED documentation. When the restart command is found in the PLUMED input PLUMED will append to the files that were generated in the run that was performed previously. No part of the PLUMED restart data is included in the LAMMPS restart files. Furthermore, any history dependent bias potentials that were accumulated in previous calculations will be read in when the RESTART command is included in the PLUMED input.

The `fix_modify energy` option is not supported by this fix.

Nothing is computed by this fix that can be accessed by any of the `output commands` within LAMMPS. All the quantities of interest can be output by commands that are native to PLUMED, however.
18.135.5 Restrictions

This fix is part of the USER-PLUMED package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

There can only be one plumed fix active at a time.

18.136.3 Description

Treats one or more sets of atoms as coupled rigid bodies. This means that each timestep the total force and torque on each rigid body is computed and the coordinates and velocities of the atoms are updated so that the collection of bodies move as a coupled set. This can be useful for treating a large biomolecule as a collection of connected, coarse-grained particles.

The coupling, associated motion constraints, and time integration is performed by the software package Parallelizable Open source Efficient Multibody Software (POEMS) which computes the constrained rigid-body motion of articulated (jointed) multibody systems (Anderson). POEMS was written and is distributed by Prof Kurt Anderson, his graduate
This fix updates the positions and velocities of the rigid atoms with a constant-energy time integration, so you should not update the same atoms via other fixes (e.g. nve, nvt, npt, temp/rescale, langevin).

Each body must have a non-degenerate inertia tensor, which means if must contain at least 3 non-collinear atoms. Which atoms are in which bodies can be defined via several options.

For option group, each of the listed groups is treated as a rigid body. Note that only atoms that are also in the fix group are included in each rigid body.

For option molecule, each set of atoms in the group with a different molecule ID is treated as a rigid body.

For option file, sets of atoms are read from the specified file and each set is treated as a rigid body. Each line of the file specifies a rigid body in the following format:

ID type atom1-ID atom2-ID atom3-ID . . .

ID as an integer from 1 to M (the number of rigid bodies). Type is any integer; it is not used by the fix poems command. The remaining arguments are IDs of atoms in the rigid body, each typically from 1 to N (the number of atoms in the system). Only atoms that are also in the fix group are included in each rigid body. Blank lines and lines that begin with '#' are skipped.

A connection between a pair of rigid bodies is inferred if one atom is common to both bodies. The POEMS solver treats that atom as a spherical joint with 3 degrees of freedom. Currently, a collection of bodies can only be connected by joints as a linear chain. The entire collection of rigid bodies can represent one or more chains. Other connection topologies (tree, ring) are not allowed, but will be added later. Note that if no joints exist, it is more efficient to use the fix rigid command to simulate the system.

When the poems fix is defined, it will print out statistics on the total # of clusters, bodies, joints, atoms involved. A cluster in this context means a set of rigid bodies connected by joints.

For computational efficiency, you should turn off pairwise and bond interactions within each rigid body, as they no longer contribute to the motion. The “neigh_modify exclude” and “delete_bonds” commands can be used to do this if each rigid body is a group.

For computational efficiency, you should only define one fix poems which includes all the desired rigid bodies. LAMMPS will allow multiple poems fixes to be defined, but it is more expensive.

The degrees-of-freedom removed by coupled rigid bodies are accounted for in temperature and pressure computations. Similarly, the rigid body contribution to the pressure virial is also accounted for. The latter is only correct if forces within the bodies have been turned off, and there is only a single fix poems defined.

18.136.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify bodyforces option is supported by this fix style to set whether per-body forces and torques are computed early or late in a timestep, i.e. at the post-force stage or at the final-integrate stage, respectively.

No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
18.136.5 Restrictions

This fix is part of the POEMS package. It is only enabled if LAMMPS was built with that package, which also requires the POEMS library be built and linked with LAMMPS. See the Build package doc page for more info.

18.137.3 Description

Insert finite-size particles or molecules into the simulation box every few timesteps within a specified region until
N particles or molecules have been inserted. This is typically used to model the pouring of granular particles into a
container under the influence of gravity. For the remainder of this doc page, a single inserted atom or molecule is
referred to as a “particle”.

If inserted particles are individual atoms, they are assigned the specified atom type. If they are molecules, the type of
each atom in the inserted molecule is specified in the file read by the molecule command, and those values are added
to the specified atom type. E.g. if the file specifies atom types 1,2,3, and those are the atom types you want for inserted
molecules, then specify type = 0. If you specify type = 2, the in the inserted molecule will have atom types 3,4,5.

All atoms in the inserted particle are assigned to two groups: the default group “all” and the group specified in the fix
pour command (which can also be “all”).
This command must use the `region` keyword to define an insertion volume. The specified region must have been previously defined with a `region` command. It must be of type `block` or a z-axis `cylinder` and must be defined with side = `in`. The cylinder style of region can only be used with 3d simulations.

Individual atoms are inserted, unless the `mol` keyword is used. It specifies a `template-ID` previously defined using the `molecule` command, which reads a file that defines the molecule. The coordinates, atom types, center-of-mass, moments of inertia, etc, as well as any bond/angle/etc and special neighbor information for the molecule can be specified in the molecule file. See the `molecule` command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

If the molecule template contains more than one molecule, the relative probability of depositing each molecule can be specified by the `molfrac` keyword. N relative probabilities, each from 0.0 to 1.0, are specified, where N is the number of molecules in the template. Each time a molecule is inserted, a random number is used to sample from the list of relative probabilities. The N values must sum to 1.0.

If you wish to insert molecules via the `mol` keyword, that will be treated as rigid bodies, use the `rigid` keyword, specifying as its value the ID of a separate `fix rigid/small` command which also appears in your input script.

**Note:** If you wish the new rigid molecules (and other rigid molecules) to be thermostatted correctly via `fix rigid/small/nvt` or `fix rigid/small/npt`, then you need to use the “fix modify dynamic/dof yes” command for the rigid fix. This is to inform that fix that the molecule count will vary dynamically.

If you wish to insert molecules via the `mol` keyword, that will have their bonds or angles constrained via SHAKE, use the `shake` keyword, specifying as its value the ID of a separate `fix shake` command which also appears in your input script.

Each timestep particles are inserted, they are placed randomly inside the insertion volume so as to mimic a stream of poured particles. If they are molecules they are also oriented randomly. Each atom in the particle is tested for overlaps with existing particles, including effects due to periodic boundary conditions if applicable. If an overlap is detected, another random insertion attempt is made; see the `vol` keyword discussion below. The larger the volume of the insertion region, the more particles that can be inserted at any one timestep. Particles are inserted again after enough time has elapsed that the previously inserted particles fall out of the insertion volume under the influence of gravity. Insertions continue every so many timesteps until the desired # of particles has been inserted.

**Note:** If you are monitoring the temperature of a system where the particle count is changing due to adding particles, you typically should use the `compute modify dynamic yes` command for the temperature compute you are using.

All other keywords are optional with defaults as shown below.

The `diam` option is only used when inserting atoms and specifies the diameters of inserted particles. There are 3 styles: `one`, `range`, or `poly`. For `one`, all particles will have diameter $D$. For `range`, the diameter of each particle will be chosen randomly and uniformly between the specified $D_{lo}$ and $D_{hi}$ bounds. For `poly`, a series of $N_{poly}$ diameters is specified. For each diameter a percentage value from 0.0 to 1.0 is also specified. The $N_{poly}$ percentages must sum to 1.0. For the example shown above with “`diam 2 0.7 0.4 1.5 0.6`”, all inserted particles will have a diameter of 0.7 or 1.5. 40% of the particles will be small; 60% will be large.

Note that for molecule insertion, the diameters of individual atoms in the molecule can be specified in the file read by the `molecule` command. If not specified, the diameter of each atom in the molecule has a default diameter of 1.0.

The `id` option has two settings which are used to determine the atom or molecule IDs to assign to inserted particles/molecules. In both cases a check is done of the current system to find the maximum current atom and molecule ID of any existing particle. Newly inserted particles and molecules are assigned IDs that increment those max values. For the `max` setting, which is the default, this check is done at every insertion step, which allows for particles to leave
the system, and their IDs to potentially be re-used. For the next setting this check is done only once when the fix is specified, which can be more efficient if you are sure particles will not be added in some other way.

The vol option specifies what volume fraction of the insertion volume will be filled with particles. For particles with a size specified by the diam range keyword, they are assumed to all be of maximum diameter $D_{hi}$ for purposes of computing their contribution to the volume fraction.

The higher the volume fraction value, the more particles are inserted each timestep. Since inserted particles cannot overlap, the maximum volume fraction should be no higher than about 0.6. Each timestep particles are inserted, LAMMPS will make up to a total of $M$ tries to insert the new particles without overlaps, where $M = \# \text{ of inserted particles} \times \text{Nattempts}$. If LAMMPS is unsuccessful at completing all insertions, it prints a warning.

The dens and vel options enable inserted particles to have a range of densities or xy velocities. The specific values for a particular inserted particle will be chosen randomly and uniformly between the specified bounds. Internally, the density value for a particle is converted to a mass, based on the radius (volume) of the particle. The $v_z$ or $v_y$ value for option vel assigns a z-velocity (3d) or y-velocity (2d) to each inserted particle.

The rate option moves the insertion volume in the z direction (3d) or y direction (2d). This enables pouring particles from a successively higher height over time.

The ignore option is useful when running a simulation that used line segment (2d) or triangle (3d) particles, typically to define boundaries for spherical granular particles to interact with. See the atom_style line or tri command for details. Lines and triangles store their size, and if the size is large it may overlap (in a spherical sense) with the insertion region, even if the line/triangle is oriented such that there is no actual overlap. This can prevent particles from being inserted. The ignore keyword causes the overlap check to skip any line or triangle particles. Obviously you should only use it if there is in fact no overlap of the line or triangle particles with the insertion region.

18.137.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. This means you must be careful when restarting a pouring simulation, when the restart file was written in the middle of the pouring operation. Specifically, you should use a new fix pour command in the input script for the restarted simulation that continues the operation. You will need to adjust the arguments of the original fix pour command to do this.

Also note that because the state of the random number generator is not saved in restart files, you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior if you adjust the fix pour parameters appropriately.

None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.137.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

For 3d simulations, a gravity fix in the -z direction must be defined for use in conjunction with this fix. For 2d simulations, gravity must be defined in the -y direction.

The specified insertion region cannot be a “dynamic” region, as defined by the region command.
18.137.6 Related commands

fix deposit, fix gravity, region

18.137.7 Default

Insertions are performed for individual particles, i.e. no mol setting is defined. If the mol keyword is used, the default for molfrac is an equal probabilities for all molecules in the template. Additional option defaults are diam = one 1.0, dens = 1.0 1.0, vol = 0.25 50, rate = 0.0, vel = 0.0 0.0 0.0 0.0 0.0 (for 3d), vel = 0.0 0.0 0.0 (for 2d), and id = max.

18.138 fix precession/spin command

18.138.1 Syntax

fix ID group precession/spin style args

- ID, group are documented in fix command
- precession/spin = style name of this fix command
- style = zeeman or anisotropy or cubic
  - zeeman args = H x y z
  - H = intensity of the magnetic field (in Tesla)
  - x y z = vector direction of the field
  - anisotropy args = K x y z
  - K = intensity of the magnetic anisotropy (in eV)
  - x y z = vector direction of the anisotropy
  - cubic args = K1 K2c nnx nny nnz nxx nxy nyy nyz nzz
  - K1 and K2c = intensity of the magnetic anisotropy (in eV)
  - nnx to nnnz = three direction vectors of the cubic anisotropy

18.138.2 Examples

fix 1 all precession/spin zeeman 0.1 0.0 0.0 1.0
fix 1 3 precession/spin anisotropy 0.001 0.0 0.0 1.0
fix 1 iron precession/spin cubic 0.001 0.0005 1.0 0.0 0.0 0.0 0.0 0.0 1.0
fix 1 all precession/spin zeeman 0.1 0.0 0.0 1.0 anisotropy 0.001 0.0 0.0 1.0

18.138.3 Description

This fix applies a precession torque to each magnetic spin in the group.

Style zeeman is used for the simulation of the interaction between the magnetic spins in the defined group and an external magnetic field:

\[ H_{Zeeman} = -g \sum_{i=0}^{N} \mu_i \vec{s}_i \cdot \vec{B}_{ext} \]

with:
- $\vec{B}_{\text{ext}}$ the external magnetic field (in T)
- $g$ the Lande factor (hard-coded as $g = 2.0$)
- $\vec{s}_i$ the unitary vector describing the orientation of spin $i$
- $\mu_i$ the atomic moment of spin $i$ given as a multiple of the Bohr magneton $\mu_B$ (for example, $\mu_i \approx 2.2$ in bulk iron).

The field value in Tesla is multiplied by the gyromagnetic ratio, $g \cdot \mu_B / \hbar$, converting it into a precession frequency in rad.THz (in metal units and with $\mu_B = 5.788 eV/T$).

As a comparison, the figure below displays the simulation of a single spin (of norm $\mu_i = 1.0$) submitted to an external magnetic field of $|B_{\text{ext}}| = 10.0$ Tesla (and oriented along the z axis). The upper plot shows the average magnetization along the external magnetic field axis and the lower plot the Zeeman energy, both as a function of temperature. The reference result is provided by the plot of the Langevin function for the same parameters.

The temperature effects are accounted for by connecting the spin $i$ to a thermal bath using a Langevin thermostat (see fix langevin/spin for the definition of this thermostat).

Style anisotropy is used to simulate an easy axis or an easy plane for the magnetic spins in the defined group:

$$H_{\text{aniso}} = -\sum_{i=1}^{N} K_{an}(\vec{r}_i) (\vec{s}_i \cdot \vec{n}_i)^2$$

with $n$ defining the direction of the anisotropy, and $K$ (in eV) its intensity. If $K > 0$, an easy axis is defined, and if $K < 0$, an easy plane is defined.

Style cubic is used to simulate a cubic anisotropy, with three possible easy axis for the magnetic spins in the defined
group:

\[ H_{\text{cubic}} = - \sum_{i=1}^{N} K_1 \left[ (\vec{s}_i \cdot \vec{n}_1)^2 (\vec{s}_i \cdot \vec{n}_2)^2 + (\vec{s}_i \cdot \vec{n}_2)^2 (\vec{s}_i \cdot \vec{n}_3)^2 + (\vec{s}_i \cdot \vec{n}_1)^2 (\vec{s}_i \cdot \vec{n}_3)^2 \right] + K_2 (\vec{s}_i \cdot \vec{n}_1)^2 (\vec{s}_i \cdot \vec{n}_2)^2 (\vec{s}_i \cdot \vec{n}_3)^2 \]

with \( K_1 \) and \( K_2 \) (in eV) the intensity coefficients and \( \vec{n}_1, \vec{n}_2 \) and \( \vec{n}_3 \) defining the three anisotropic directions defined by the command (from \( n1x \) to \( n3z \)). For \( \vec{n}_1 = (100) \), \( \vec{n}_2 = (010) \), and \( \vec{n}_3 = (001) \), \( K_1 < 0 \) defines an iron type anisotropy (easy axis along the \( (001) \)-type cube edges), and \( K_1 > 0 \) defines a nickel type anisotropy (easy axis along the \( (111) \)-type cube diagonals). \( K_2 > 0 \) also defines easy axis along the \( (111) \)-type cube diagonals. See chapter 2 of [Skomski](skomski) for more details on cubic anisotropies.

In all cases, the choice of \( (xyz) \) only imposes the vector directions for the forces. Only the direction of the vector is important; its length is ignored (the entered vectors are normalized).

Those styles can be combined within one single command line.

### 18.138.4 Restart, fix_modify, output, run start/stop, minimize info

By default, the energy associated to this fix is not added to the potential energy of the system. The fix_modify energy option is supported by this fix to add this magnetic potential energy to the potential energy of the system,

```
fix 1 all precession/spin zeeman 1.0 0.0 0.0 1.0
fix_modify 1 energy yes
```

This fix computes a global scalar which can be accessed by various output commands.

No information about this fix is written to binary restart files.

### 18.138.5 Restrictions

The precession/spin style is part of the SPIN package. This style is only enabled if LAMMPS was built with this package, and if the atom_style “spin” was declared. See the Build package doc page for more info.

The precession/spin style can only be declared once. If more than one precession type (for example combining an anisotropy and a Zeeman interactions) has to be declared, they have to be chained in the same command line (as shown in the examples above).

```

18.139.3 Description

Reset the pressure of the system by using a Berendsen barostat (Berendsen), which rescales the system volume and (optionally) the atoms coordinates within the simulation box every timestep.

Regardless of what atoms are in the fix group, a global pressure is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword `dilate` is specified with a value of `partial`, in which case only the atoms in the fix group are re-scaled. The latter can be useful for leaving the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

**Note:** Unlike the `fix npt` or `fix nph` commands which perform Nose/Hoover barostatting AND time integration, this fix does NOT perform time integration. It only modifies the box size and atom coordinates to effect barostatting. Thus you must use a separate time integration fix, like `fix nve` or `fix nvt` to actually update the positions and velocities of atoms. This fix can be used in conjunction with thermostatting fixes to control the temperature, such as `fix nvt` or `fix langevin` or `fix temp/berendsen`.

See the Howto barostat doc page for a discussion of different ways to perform barostatting.

The barostat is specified using one or more of the `iso`, `aniso`, `x`, `y`, `z`, and `couple` keywords. These keywords give you the ability to specify the 3 diagonal components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation. Unlike the
fix npt and fix nph commands, this fix cannot be used with triclinic (non-orthogonal) simulation boxes to control all 6 components of the general pressure tensor.

The target pressures for each of the 3 diagonal components of the stress tensor can be specified independently via the \( x \), \( y \), and \( z \), keywords, which correspond to the 3 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from \( P_{start} \) to \( P_{stop} \). If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the \( y \) keyword is used, the y-box length will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the fix deform command.

For all barostat keywords, the \( P_{damp} \) parameter determines the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (tau or fs or ps - see the units command).

**Note:** A Berendsen barostat will not work well for arbitrary values of \( P_{damp} \). If \( P_{damp} \) is too small, the pressure and volume can fluctuate wildly; if it is too large, the pressure will take a very long time to equilibrate. A good choice for many models is a \( P_{damp} \) of around 1000 timesteps. However, note that \( P_{damp} \) is specified in time units, and that timesteps are NOT the same as time units for most units settings.

**Note:** The relaxation time is actually also a function of the bulk modulus of the system (inverse of isothermal compressibility). The bulk modulus has units of pressure and is the amount of pressure that would need to be applied (isotropically) to reduce the volume of the system by a factor of 2 (assuming the bulk modulus was a constant, independent of density, which it’s not). The bulk modulus can be set via the keyword modulus. The \( P_{damp} \) parameter is effectively multiplied by the bulk modulus, so if the pressure is relaxing faster than expected or desired, increasing the bulk modulus has the same effect as increasing \( P_{damp} \). The converse is also true. LAMMPS does not attempt to guess a correct value of the bulk modulus; it just uses 10.0 as a default value which gives reasonable relaxation for a Lennard-Jones liquid, but will be way off for other materials and way too small for solids. Thus you should experiment to find appropriate values of \( P_{damp} \) and/or the modulus when using this fix.

The \textit{couple} keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, \( xz \) means the \( P_{xx} \) and \( P_{zz} \) components of the stress tensor are coupled. \( xyz \) means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The \( P_{start} \), \( P_{stop} \), \( P_{damp} \) parameters for any coupled dimensions must be identical. \textit{Couple xyz} can be used for a 2d simulation; the \( z \) dimension is simply ignored.

The \textit{iso} and \textit{aniso} keywords are simply shortcuts that are equivalent to specifying several other keywords together.

The keyword \textit{iso} means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “iso \( P_{start} \) \( P_{stop} \) \( P_{damp} \)” is the same as specifying these 4 keywords:

\[
\begin{align*}
x & \ P_{start} \ P_{stop} \ P_{damp} \\
y & \ P_{start} \ P_{stop} \ P_{damp} \\
z & \ P_{start} \ P_{stop} \ P_{damp} \\
couple & \ xyz
\end{align*}
\]

The keyword \textit{aniso} means \( x \), \( y \), and \( z \) dimensions are controlled independently using the \( P_{xx} \), \( P_{yy} \), and \( P_{zz} \) components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “aniso \( P_{start} \) \( P_{stop} \) \( P_{damp} \)” is the same as specifying these 4 keywords:
This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp group-ID temp
compute fix-ID_press group-ID pressure fix-ID_temp
```

See the `compute temp` and `compute pressure` commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is the same as the fix group.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp` and `thermo_press`. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

### 18.139.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to `binary restart files`.

The `fix_modify temp` and `press` options are supported by this fix. You can use them to assign a `compute` you have defined to this fix which will be used in its temperature and pressure calculations. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

No global or per-atom quantities are stored by this fix for access by various `output commands`.

This fix can ramp its target pressure over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

This fix is not invoked during `energy minimization`.

### 18.139.5 Restrictions

Any dimension being adjusted by this fix must be periodic.

- print = style name of this fix command
- N = print every N steps; N can be a variable (see below)
- string = text string to print with optional variable names
- zero or more keyword/value pairs may be appended
- keyword = file or append or screen or title

```
file value = filename
append value = filename
screen value = yes or no
title value = string
        string = text to print as 1st line of output file
```

18.140.2 Examples

```
fix extra all print 100 "Coords of marker atom = $x $y $z"
fix extra all print 100 "Coords of marker atom = $x $y $z" file coord.txt
```

18.140.3 Description

Print a text string every N steps during a simulation run. This can be used for diagnostic purposes or as a debugging tool to monitor some quantity during a run. The text string must be a single argument, so it should be enclosed in double quotes if it is more than one word. If it contains variables it must be enclosed in double quotes to insure they are not evaluated when the input script line is read, but will instead be evaluated each time the string is printed.

Instead of a numeric value, N can be specified as an equal-style variable, which should be specified as v_name, where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which the string will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the stagger() and logfreq() and stride() math functions for equal-style variables, as examples of useful functions to use in this context. For example, the following commands will print output at timesteps 10,20,30,100,200,300,1000,2000,etc:

```
variable s equal logfreq(10,3,10)
fix extra all print v_s "Coords of marker atom = $x $y $z"
```
The specified group-ID is ignored by this fix.

See the `variable` command for a description of `equal` style variables which are the most useful ones to use with the fix print command, since they are evaluated afresh each timestep that the fix print line is output. Equal-style variables calculate formulas involving mathematical operations, atom properties, group properties, thermodynamic properties, global values calculated by a `compute` or `fix`, or references to other variables.

If the `file` or `append` keyword is used, a filename is specified to which the output generated by this fix will be written. If `file` is used, then the filename is overwritten if it already exists. If `append` is used, then the filename is appended to if it already exists, or created if it does not exist.

If the `screen` keyword is used, output by this fix to the screen and logfile can be turned on or off as desired.

The `title` keyword allow specification of the string that will be printed as the first line of the output file, assuming the `file` keyword was used. By default, the title line is as follows:

```plaintext
# Fix print output for fix ID
```

where ID is replaced with the fix-ID.

### 18.140.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to `binary restart files`. None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various `output commands`. No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during `energy minimization`.

### 18.140.5 Restrictions

none

### 18.140.6 Related commands

`variable`, `print`

### 18.140.7 Default

The option defaults are no file output, `screen = yes`, and title string as described above.

### 18.141 fix propel/self command

#### 18.141.1 Syntax

```
fix ID group-ID propel/self mode magnitude keyword values ...
```

- ID, group-ID are documented in `fix` command
- `propel/self` = style name of this fix command
- `mode` = velocity or quat
- `magnitude` = magnitude of the active force
- one or more keyword/value pairs may be appended to args
• keyword = types
  types values = one or more atom types

18.141.2 Examples

```fortran
fix active_group all propel/self velocity 1.0
fix constant_velocity all viscous 1.0
fix active_group all propel/self quat 1.0
fix active all propel/self quat 1.0 types 1 2 4
```

18.141.3 Description

Adds a force of a constant magnitude to each atom in the group. The nature in which the force is added depends on the mode.

For `mode = velocity`, the active force acts along the velocity vector of each atom. This can be interpreted as a velocity-dependent friction, such as proposed by \(\text{(Erdmann)}\).

For `mode = quat` the force is applied along the axis obtained by rotating the x-axis along the atom’s quaternion. In other words, the force is along the x-axis in the atom’s body frame. This mode requires all atoms in the group to have a quaternion, so atom_style should either be ellipsoid or body. In combination with Langevin thermostat for translation and rotation in the overdamped regime, the quaternion mode corresponds to the active Brownian particle model introduced by \(\text{(Henkes), (Bialke) and (Fily)}\).

By default, this fix is applied to all atoms in the group. You can override this behavior by specifying the atom types the fix should work on through the `types` keyword.

18.141.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.
This fix is not imposed during minimization.

18.141.5 Restrictions

In quat mode, this fix makes use of per-atom quaternions to take into account the fact that the orientation can rotate and hence the direction of the active force can change. The quat mode of this fix only works with atom_style ellipsoid.

18.141.6 Related commands

`fix setforce, fix addforce`

types

18.142 fix property/atom command

Accelerator Variants: property/atom/kk

18.142.1 Syntax

```
fix ID group-ID property/atom vec1 vec2 ... keyword value ...
```

- ID, group-ID are documented in `fix` command
- property/atom = style name of this fix command
- vec1,vec2,... = mol or q or rmass or i_name or d_name
  - mol = molecule IDs
  - q = charge
  - rmass = per-atom mass
  - i_name = new integer vector referenced by name
  - d_name = new floating-point vector referenced by name
- zero or more keyword/value pairs may be appended
- keyword = ghost
  - ghost value = no or yes for whether ghost atom info in communicated

18.142.2 Examples

```
fix 1 all property/atom mol
fix 1 all property/atom i_myflag1 i_myflag2
fix 1 all property/atom d_sx d_sy d_sz
```

18.142.3 Description

Create one or more additional per-atom vectors to store information about atoms and to use during a simulation. The specified group-ID is ignored by this fix.

The atom style used for a simulation defines a set of per-atom properties, as explained on the `atom_style` and `read_data` doc pages. The latter command allows these properties to be defined for each atom in the system when a data file is read. This fix will augment the set of properties with new custom ones. This can be useful in several scenarios.

If the atom style does not define molecule IDs, per-atom charge, or per-atom mass, they can be added using the mol, q or rmass keywords. This can be useful, e.g. to define “molecules” to use as rigid bodies with the `fix rigid` command, or just to carry around an extra flag with the atoms (stored as a molecule ID) that can be used to group atoms without having to use the group command (which is limited to a total of 32 groups including all).

Another application would be to use the rmass flag in order to have per-atom masses instead of per-type masses, for example this can be useful to study isotope effects with partial isotope substitution. Please see below for an example of simulating a mixture of light and heavy water with the TIP4P water potential.
An alternative to using `fix property/atom` in these ways is to use an atom style that does define molecule IDs or charge or per-atom mass (indirectly via diameter and density) or to use a hybrid atom style that combines two or more atom styles to provide the union of all atom properties. However, this has two practical drawbacks: first, it typically necessitates changing the format of the data file, which can be tedious for large systems; and second, it may define additional properties that are not needed such as bond lists, which has some overhead when there are no bonds.

In the future, we may add additional per-atom properties similar to `mol`, `q` or `rmass`, which “turn-on” specific properties defined by some atom styles, so they can be used by atom styles that do not define them.

More generally, the `_name` and `d_name` vectors allow one or more new custom per-atom properties to be defined. Each name must be unique and can use alphanumeric or underscore characters. These vectors can store whatever values you decide are useful in your simulation. As explained below there are several ways to initialize and access and output these values, both via input script commands and in new code that you add to LAMMPS.

This is effectively a simple way to add per-atom properties to a model without needing to write code for a new `atom style` that defines the properties. Note however that implementing a new atom style allows new atom properties to be more tightly and seamlessly integrated with the rest of the code.

The new atom properties encode values that migrate with atoms to new processors and are written to restart files. If you want the new properties to also be defined for ghost atoms, then use the `ghost` keyword with a value of `yes`. This will invoke extra communication when ghost atoms are created (at every re-neighboring) to insure the new properties are also defined for the ghost atoms.

**Properties on ghost atoms**

If you use this command with the `mol`, `q` or `rmass` vectors, then you most likely want to set `ghost` yes, since these properties are stored with ghost atoms if you use an `atom_style` that defines them, and many LAMMPS operations that use molecule IDs or charge, such as neighbor lists and pair styles, will expect ghost atoms to have these values. LAMMPS will issue a warning it you define those vectors but do not set `ghost` yes.

**Limitations on ghost atom properties**

The properties for ghost atoms are not updated every timestep, but only once every few steps when neighbor lists are re-built. Thus the `ghost` keyword is suitable for static properties, like molecule IDs, but not for dynamic properties that change every step. For the latter, the code you add to LAMMPS to change the properties will also need to communicate their new values to/from ghost atoms, an operation that can be invoked from within a `pair style` or `fix` or `compute` that you write.

This fix is one of a small number that can be defined in an input script before the simulation box is created or atoms are defined. This is so it can be used with the `read_data` command as described below.

**Note:** If this fix is defined after the simulation box is created, a ‘run 0’ command may be needed to properly initialize the storage created by this fix.

Per-atom properties that are defined by the `atom style` are initialized when atoms are created, e.g. by the `read_data` or `create_atoms` commands. The per-atom properties defined by this fix are not. So you need to initialize them explicitly. This can be done by the `read_data` command, using its `fix` keyword and passing it the fix-ID of this fix.

Thus these commands:

```
fix prop all property/atom mol d_flag
read_data data.txt fix prop NULL Molecules
```
would allow a data file to have a section like this:

```
<table>
<thead>
<tr>
<th>Molecules</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 4 1.5</td>
</tr>
<tr>
<td>2 4 3.0</td>
</tr>
<tr>
<td>3 10 1.0</td>
</tr>
<tr>
<td>4 10 1.0</td>
</tr>
<tr>
<td>5 10 1.0</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>N 763 4.5</td>
</tr>
</tbody>
</table>
```

where N is the number of atoms, and the first field on each line is the atom-ID, followed by a molecule-ID and a floating point value that will be stored in a new property called “flag”. Note that the list of per-atom properties can be in any order.

Another way of initializing the new properties is via the `set` command. For example, if you wanted molecules defined for every set of 10 atoms, based on their atom-IDs, these commands could be used:

```
fix prop all property/atom mol
variable cluster atom ((id-1)/10)+1
set atom * mol v_cluster
```

The *atom-style variable* will create values for atoms with IDs 31,32,33,…40 that are 4.0,4.1,4.2,…,4.9. When the `set` commands assigns them to the molecule ID for each atom, they will be truncated to an integer value, so atoms 31-40 will all be assigned a molecule ID of 4.

Note that *atomfile-style variables* can also be used in place of atom-style variables, which means in this case that the molecule IDs could be read-in from a separate file and assigned by the `set` command. This allows you to initialize new per-atom properties in a completely general fashion.

For new atom properties specified as `i_name` or `d_name`, the `compute property/atom` command can access their values. This means that the values can be output via the `dump custom` command, accessed by fixes like `fix ave/atom`, accessed by other computes like `compute reduce`, or used in *atom-style variables*.

For example, these commands will output two new properties to a custom dump file:

```
fix prop all property/atom i_flag1 d_flag2
compute 1 all property/atom i_flag1 d_flag2
dump 1 all custom 100 tmp.dump id x y z c_1[1] c_1[2]
```

If you wish to add new `pair styles`, `fixes`, or `computes` that use the per-atom properties defined by this fix, see the `Modify atom` doc page which has details on how the properties can be accessed from added classes.

Example for using per-atom masses with TIP4P water to study isotope effects. When setting up simulations with the TIP4P `pair styles` for water, you have to provide exactly one atom type each to identify the water oxygen and hydrogen atoms. Since the atom mass is normally tied to the atom type, this makes it impossible to study multiple isotopes in the same simulation. With `fix property/atom rmass` however, the per-type masses are replaced by per-atom masses. Assuming you have a working input deck for regular TIP4P water, where water oxygen is atom type 1 and water hydrogen is atom type 2, the following lines of input script convert this to using per-atom masses:

```
fix Isotopes all property/atom rmass ghost yes
set type 1 mass 15.9994
set type 2 mass 1.008
```
When writing out the system data with the `write_data` command, there will be a new section named with the fix-ID (i.e. `Isotopes` in this case). Alternatively, you can take an existing data file and just add this `Isotopes` section with one line per atom containing atom-ID and mass. Either way, the extended data file can be read back with:

```plaintext
fix Isotopes all property/atom rmass ghost yes
read_data tip4p-isotopes.data fix Isotopes NULL Isotopes
```

Please note that the first `Isotopes` refers to the fix-ID and the second to the name of the section. The following input script code will now change the first 100 water molecules in this example to heavy water:

```plaintext
group hwat id 2:3003:
group hwat id 3:3003:
set group hwat mass 2.0141018
```

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

### 18.142.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the per-atom values it stores to binary restart files, so that the values can be restored when a simulation is restarted. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Warning:** When reading data from a restart, the fix command has to be specified exactly the same way as before. LAMMPS will only check whether a fix is of the same style and has the same fix ID and in case of a match will then try to initialize the fix with the data stored in the binary restart file. If the fix property/atom command does not match exactly, data can be corrupted or LAMMPS may crash.

None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various `output` commands. No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.
18.142.5 Restrictions

none

18.142.6 Related commands

18.143 fix python:invoke command

18.143.1 Syntax

fix ID group-ID python:invoke N callback function_name

- ID, group-ID are ignored by this fix
- python:invoke = style name of this fix command
- N = execute every N steps
- callback = post_force or end_of_step
  
  post_force = callback after force computations on atoms every N time steps
  end_of_step = callback after every N time steps

18.143.2 Examples

```python
post_force_callback here ""
from lammps import lammps
def post_force_callback(lammps_ptr, vflag):
    lmp = lammps(ptr=lammps_ptr)
    # access LAMMPS state using Python interface
""
end_of_step_callback here ""
def end_of_step_callback(lammps_ptr):
    lmp = lammps(ptr=lammps_ptr)
    # access LAMMPS state using Python interface
""

fix pf all python:invoke 50 post_force post_force_callback
fix eos all python:invoke 50 end_of_step end_of_step_callback
```
18.143.3 Description

This fix allows you to call a Python function during a simulation run. The callback is either executed after forces have been applied to atoms or at the end of every N time steps.

Callback functions must be declared in the global scope of the active Python interpreter. This can either be done by defining it inline using the python command or by importing functions from other Python modules. If LAMMPS is driven using the library interface from Python, functions defined in the driving Python interpreter can also be executed.

Each callback is given a pointer object as first argument. This can be used to initialize an instance of the lammps Python interface, which gives access to the LAMMPS state from Python.

**Warning:** While you can access the state of LAMMPS via library functions from these callbacks, trying to execute input script commands will in the best case not work or in the worst case result in undefined behavior.

18.143.4 Restrictions

This fix is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

Building LAMMPS with the PYTHON package will link LAMMPS with the Python library on your system. Settings to enable this are in the lib/python/Makefile.lammps file. See the lib/python/README file for information on those settings.

18.143.5 Related commands

*python command*

18.144 fix python/move command

18.144.1 Syntax

```
fix python/move pymodule.CLASS
```

`pymodule.CLASS = use class CLASS in module/file pymodule` to compute how to move atoms

18.144.2 Examples

```
fix  1 all python/move py_nve.NVE
fix  1 all python/move py_nve.NVE_OPT
```
18.144.3 Description

The *python/move* fix style provides a way to define ways how particles are moved during an MD run from python script code, that is loaded from a file into LAMMPS and executed at the various steps where other fixes can be executed. This python script must contain specific python class definitions.

This allows to implement complex position updates and also modified time integration methods. Due to python being an interpreted language, however, the performance of this fix can be moderately to significantly slower than the corresponding C++ code. For specific cases, this performance penalty can be limited through effective use of NumPy.

The python module file has to start with the following code:

```python
from __future__ import print_function
import lammps
import ctypes
import traceback
import numpy as np
#
class LAMMPSFix(object):
    def __init__(self, ptr, group_name="all"):
        self.lmp = lammps.lammps(ptr=ptr)
        self.group_name = group_name
#
class LAMMPSFixMove(LAMMPSFix):
    def __init__(self, ptr, group_name="all"):
        super(LAMMPSFixMove, self).__init__(ptr, group_name)
    
    def init(self):
        pass
    
    def initial_integrate(self, vflag):
        pass
    
    def final_integrate(self):
        pass
    
    def initial_integrate_respa(self, vflag, ilevel, iloop):
        pass
    
    def final_integrate_respa(self, ilevel, iloop):
        pass
    
    def reset_dt(self):
        pass
```

Any classes implementing new atom motion functionality have to be derived from the *LAMMPSFixMove* class, overriding the available methods as needed.

Examples for how to do this are in the *examples/python* folder.
18.144.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.144.5 Restrictions

This pair style is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.145 fix qbmsst command

18.145.1 Syntax

```
fix ID group-ID qbmsst dir shockvel keyword value ...
```

- ID, group-ID are documented in fix command
- qbmsst = style name of this fix
- dir = x or y or z
- shockvel = shock velocity (strictly positive, velocity units)
- zero or more keyword/value pairs may be appended
- keyword = q or mu or p0 or v0 or e0 or tscale or damp or seed or f_max or N_f or eta or beta or T_init
  
  q value = cell mass-like parameter (mass^2/distance^4 units)
  mu value = artificial viscosity (mass/distance/time units)
  p0 value = initial pressure in the shock equations (pressure units)
  v0 value = initial simulation cell volume in the shock equations
  e0 value = initial total energy (energy units)
  tscale value = reduction in initial temperature (unitless fraction between 0.0 and 1.0)
  damp value = damping parameter {time units} inverse of friction gamma
  seed value = random number seed (positive integer)
  f_max value = upper cutoff frequency of the vibration spectrum {1/time units}
  N_f value = number of frequency bins (positive integer)
  eta value = coupling constant between the shock system and the quantum thermal bath (positive unitless)
**beta value** = the quantum temperature is updated every beta time steps
(positive integer)

**T_init value** = quantum temperature for the initial state (temperature units)

### 18.145.2 Examples

```plaintext
# (liquid methane modeled with the REAX force field, real units)
fix 1 all qbmsst z 0.122 q 25 mu 0.9 tscale 0.01 damp 200 seed 35082 f_max 0.3 N_f_100 eta 1 beta 400 T_init 110
# (quartz modeled with the BKS force field, metal units)
fix 2 all qbmsst z 72 q 40 tscale 0.05 damp 1 seed 47508 f_max 120.0 N_f 100 eta 1.0 beta 500 T_init 300
```

Two example input scripts are given, including shocked α-quartz and shocked liquid methane. The input script first equilibrates an initial state with the quantum thermal bath at the target temperature and then applies `fix qbmsst` to simulate shock compression with quantum nuclear correction. The following two figures plot relevant quantities for shocked α-quartz.

**Figure 1.** Classical temperature $T_{cl} = \sum \frac{m_i v_i^2}{3Nk_B}$ vs. time for coupling the α-quartz initial state with the quantum thermal bath at target quantum temperature $T^{qm} = 300K$. The NpH ensemble is used for time integration while QTB provides the colored random force. $T^{cl}$ converges at the timescale of `damp` which is set to be 1 ps.

**Figure 2.** Quantum temperature and pressure vs. time for simulating shocked α-quartz with `fix qbmsst`. The shock propagates along the z direction. Restart of the `fix qbmsst` command is demonstrated in the example input script. Thermodynamic quantities stay continuous before and after the restart.
18.145.3 Description

This command performs the Quantum-Bath coupled Multi-Scale Shock Technique (QBMSST) integration. See (Qi) for a detailed description of this method. QBMSST provides description of the thermodynamics and kinetics of shock processes while incorporating quantum nuclear effects. The \textit{shockvel} setting determines the steady shock velocity that will be simulated along direction \textit{dir}.

Quantum nuclear effects (\texttt{fix qtb}) can be crucial especially when the temperature of the initial state is below the classical limit or there is a great change in the zero point energies between the initial and final states. Theoretical post processing quantum corrections of shock compressed water and methane have been reported as much as 30\% of the temperatures (Goldman). A self-consistent method that couples the shock to a quantum thermal bath described by a colored noise Langevin thermostat has been developed by Qi et al (Qi) and applied to shocked methane. The onset of chemistry is reported to be at a pressure on the shock Hugoniot that is 40\% lower than observed with classical molecular dynamics.

It is highly recommended that the system be already in an equilibrium state with a quantum thermal bath at temperature of \textit{T\_init}. The \texttt{fix} \texttt{qib} at constant temperature \textit{T\_init} could be used before applying this command to introduce self-consistent quantum nuclear effects into the initial state.

The parameters \textit{q}, \textit{mu}, \textit{e0}, \textit{p0}, \textit{v0} and \textit{tscale} are described in the command \texttt{fix msst}. The values of \textit{e0}, \textit{p0}, or \textit{v0} will be calculated on the first step if not specified. The parameter of \textit{damp}, \textit{f\_max}, and \textit{N\_f} are described in the command \texttt{fix qtb}.

The \texttt{fix qbmsst} command couples the shock system to a quantum thermal bath with a rate that is proportional to the change of the total energy of the shock system, \(E_{\text{tot}} - E_{\text{tot}}^0\). Here \(E_{\text{tot}}\) consists of both the system energy and a thermal term, see (Qi), and \(E_{\text{tot}}^0 = e0\) is the initial total energy.

The \textit{eta (\(\eta\))} parameter is a unitless coupling constant between the shock system and the quantum thermal bath. A small \(\eta\) value cannot adjust the quantum temperature fast enough during the temperature ramping period of shock compression while large \(\eta\) leads to big temperature oscillation. A value of \(\eta\) between 0.3 and 1 is usually appropriate for simulating most systems under shock compression. We observe that different values of \(\eta\) lead to almost the same final thermodynamic state behind the shock, as expected.

The quantum temperature is updated every \textit{beta (\(\beta\))} steps with an integration time interval \(\beta\) times longer than the simulation time step. In that case, \(E_{\text{tot}}\) is taken as its average over the past \(\beta\) steps. The temperature of the quantum thermal bath \(T_{\text{qm}}\) changes dynamically according to the following equation where \(\Delta t\) is the MD time step and \(\gamma\) is the friction constant which is equal to the inverse of the \textit{damp} parameter.

\[
\frac{dT_{\text{qm}}}{dt} = \gamma \eta \sum_{l=1}^{\beta} \frac{E_{\text{tot}}(t - l\Delta t) - E_{\text{tot}}^0}{3\beta N k_B}
\]

The parameter \textit{T\_init} is the initial temperature of the quantum thermal bath and the system before shock loading.

For all pressure styles, the simulation box stays orthorhombic in shape. Parrinello-Rahman boundary conditions (tilted box) are supported by LAMMPS, but are not implemented for QBMSST.
18.145.4 Restart, fix_modify, output, run start/stop, minimize info

Because the state of the random number generator is not written to binary restart files, this fix cannot be restarted “exactly” in an uninterrupted fashion. However, in a statistical sense, a restarted simulation should produce similar behaviors of the system as if it is not interrupted. To achieve such a restart, one should write explicitly the same value for \( q, \mu, \text{damp}, f_{\text{max}}, N_f, \eta, \text{and } \beta \) and set \( tscale = 0 \) if the system is compressed during the first run.

The progress of the QBMSST can be monitored by printing the global scalar and global vector quantities computed by the fix. The global vector contains five values in this order:

\[ \text{[dhugoniot, drayleigh, lagrangian\_speed, lagrangian\_position, quantum\_temperature]} \]

1. \( \text{dhugoniot} \) is the departure from the Hugoniot (temperature units).
2. \( \text{drayleigh} \) is the departure from the Rayleigh line (pressure units).
3. \( \text{lagrangian\_speed} \) is the laboratory-frame Lagrangian speed (particle velocity) of the computational cell (velocity units).
4. \( \text{lagrangian\_position} \) is the computational cell position in the reference frame moving at the shock speed. This is the distance of the computational cell behind the shock front.
5. \( \text{quantum\_temperature} \) is the temperature of the quantum thermal bath \( T_{qm} \).

To print these quantities to the log file with descriptive column headers, the following LAMMPS commands are suggested. Here the \textit{fix_modify} energy command is also enabled to allow the thermo keyword \textit{etotal} to print the quantity \( E^{tot} \). See also the \textit{thermo\_style} command.

\[
\begin{align*}
\text{fix} & \quad \text{fix\_id all msst z} \\
\text{fix\_modify} & \quad \text{fix\_id energy yes} \\
\text{variable} & \quad \text{dhug} \quad \text{equal } f_{\text{fix\_id[1]}} \\
\text{variable} & \quad \text{dray} \quad \text{equal } f_{\text{fix\_id[2]}} \\
\text{variable} & \quad \text{lgr\_vel} \quad \text{equal } f_{\text{fix\_id[3]}} \\
\text{variable} & \quad \text{lgr\_pos} \quad \text{equal } f_{\text{fix\_id[4]}} \\
\text{variable} & \quad \text{T\_qm} \quad \text{equal } f_{\text{fix\_id[5]}} \\
\text{thermo\_style} & \quad \text{custom step temp ke pe lz pzz etotal v\_dhug v\_dray v\_lgr\_vel v\_lgr\_pos v\_T\_qm f\_fix\_id}
\end{align*}
\]

The global scalar under the entry \( f_{\text{fix\_id}} \) is the quantity of thermo energy as an extra part of \( E^{tot} \). This global scalar and the vector of 5 quantities can be accessed by various \textit{output commands}. It is worth noting that the temp keyword under the \textit{thermo\_style} command print the instantaneous classical temperature \( T^{cl} \) as described in the command \textit{fix qtb}.

18.145.5 Restrictions

This fix style is part of the USER-QTB package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

All cell dimensions must be periodic. This fix can not be used with a triclinic cell. The QBMSST fix has been tested only for the group-ID all.
18.145.6 Related commands

fix qtb, fix msst

18.145.7 Default

The keyword defaults are q = 10, mu = 0, tscale = 0.01, damp = 1, seed = 880302, f_max = 200.0, N_f = 100, eta = 1.0, beta = 100, and T_init=300.0. e0, p0, and v0 are calculated on the first step.

18.147 fix qeq/shielded command

18.148 fix qeq/slater command

18.149 fix qeq/dynamic command

18.150 fix qeq/fire command

18.150.1 Syntax

```
fix ID group-ID style Nevery cutoff tolerance maxiter qfile keyword ...
```

- ID, group-ID are documented in fix command
- style = qeq/point or qeq/shielded or qeq/slater or qeq/dynamic or qeq/fire
- Nevery = perform charge equilibration every this many steps
- cutoff = global cutoff for charge-charge interactions (distance unit)
- tolerance = precision to which charges will be equilibrated
- maxiter = maximum iterations to perform charge equilibration
- qfile = a filename with QEq parameters or coul/streitz or reax/c
- zero or more keyword/value pairs may be appended
- keyword = alpha or qdamp or qstep

alpha value = Slater type orbital exponent (qeq/slater only)
qdamp value = damping factor for damped dynamics charge solver (qeq/
dynamic and qeq/fire only)
qstep value = time step size for damped dynamics charge solver (qeq/
dynamic and qeq/fire only)
18.150.2 Examples

```plaintext

fix 1 all qeq/fire 1 10 1.0e-3 100 my_qeq qdamp 0.2 qstep 0.1
```

18.150.3 Description

Perform the charge equilibration (QEq) method as described in *Rappe and Goddard* and formulated in *Nakano* (also known as the matrix inversion method) and in *Rick and Stuart* (also known as the extended Lagrangian method) based on the electronegativity equilization principle.

These fixes can be used with any pair style in LAMMPS, so long as per-atom charges are defined. The most typical use-case is in conjunction with a pair style that performs charge equilibration periodically (e.g. every timestep), such as the ReaxFF or Streitz-Mintmire potential. But these fixes can also be used with potentials that normally assume per-atom charges are fixed, e.g. a Buckingham or LJ/Coulombic potential.

Because the charge equilibration calculation is effectively independent of the pair style, these fixes can also be used to perform a one-time assignment of charges to atoms. For example, you could define the QEq fix, perform a zero-timestep run via the run command without any pair style defined which would set per-atom charges (based on the current atom configuration), then remove the fix via the unfix command before performing further dynamics.

**Note:** Computing and using charge values different from published values defined for a fixed-charge potential like Buckingham or CHARMM or AMBER, can have a strong effect on energies and forces, and produces a different model than the published versions.

**Note:** The fix qeq/comb command must still be used to perform charge equilibration with the COMB potential. The fix qeq/reax command can be used to perform charge equilibration with the ReaxFF force field, although fix qeq/shielded yields the same results as fix qeq/reax if Nevery, cutoff, and tolerance are the same. Eventually the fix qeq/reax command will be deprecated.

The QEq method minimizes the electrostatic energy of the system (or equalizes the derivative of energy with respect to charge of all the atoms) by adjusting the partial charge on individual atoms based on interactions with their neighbors within cutoff. It requires a few parameters, in metal units, for each atom type which provided in a file specified by qfile. The file has the following format

```plaintext
1 chi eta gamma zeta qcore
2 chi eta gamma zeta qcore
... Ntype chi eta gamma zeta qcore
```

There have to be parameters given for every atom type. Wildcard entries are possible using the same syntax as elsewhere in LAMMPS (i.e., n*m, n*, *m, *). Later entries will overwrite previous ones. Empty lines or any text following the pound sign (#) are ignored. Each line starts with the atom type followed by five parameters. Only a subset of the parameters is used by each QEq style as described below, thus the others can be set to 0.0 if desired, but all five entries per line are required.

- **chi** = electronegativity in energy units
- **eta** = self-Coulomb potential in energy units
• \textit{gamma} = shielded Coulomb constant defined by \textit{ReaxFF force field} in distance units

• \textit{zeta} = Slater type orbital exponent defined by the \textit{Streitz-Mintmire} potential in reverse distance units

• \textit{qcore} = charge of the nucleus defined by the \textit{Streitz-Mintmire potential} potential in charge units

The \textit{qeq/point} style describes partial charges on atoms as point charges. Interaction between a pair of charged particles is \(1/r\), which is the simplest description of the interaction between charges. Only the \textit{chi} and \textit{eta} parameters from the \textit{qfile} file are used. Note that Coulomb catastrophe can occur if repulsion between the pair of charged particles is too weak. This style solves partial charges on atoms via the matrix inversion method. A tolerance of 1.0e-6 is usually a good number.

The \textit{qeq/shielded} style describes partial charges on atoms also as point charges, but uses a shielded Coulomb potential to describe the interaction between a pair of charged particles. Interaction through the shielded Coulomb is given by equation (13) of the \textit{ReaxFF force field} paper. The shielding accounts for charge overlap between charged particles at small separation. This style is the same as \textit{fix qeq/reax}, and can be used with \textit{pair_style reax/c}. Only the \textit{chi}, \textit{eta}, and \textit{gamma} parameters from the \textit{qfile} file are used. When using the string \textit{reax/c} as filename, these parameters are extracted directly from an active \textit{reax/c} pair style. This style solves partial charges on atoms via the matrix inversion method. A tolerance of 1.0e-6 is usually a good number.

The \textit{qeq/slater} style describes partial charges on atoms as spherical charge densities centered around atoms via the Slater 1s orbital, so that the interaction between a pair of charged particles is the product of two Slater 1s orbitals. The expression for the Slater 1s orbital is given under equation (6) of the \textit{Streitz-Mintmire} paper. Only the \textit{chi}, \textit{eta}, \textit{zeta}, and \textit{qcore} parameters from the \textit{qfile} file are used. When using the string \textit{coul/streitz} as filename, these parameters are extracted directly from an active \textit{coul/streitz} pair style. This style solves partial charges on atoms via the matrix inversion method. A tolerance of 1.0e-6 is usually a good number. Keyword \textit{alpha} can be used to change the Slater type orbital exponent.

The \textit{qeq/dynamic} style describes partial charges on atoms as point charges that interact through \(1/r\), but the extended Lagrangian method is used to solve partial charges on atoms. Only the \textit{chi} and \textit{eta} parameters from the \textit{qfile} file are used. Note that Coulomb catastrophe can occur if repulsion between the pair of charged particles is too weak. A tolerance of 1.0e-3 is usually a good number. Keyword \textit{qdamp} can be used to change the damping factor, while keyword \textit{qstep} can be used to change the time step size.

The \textit{*qeq/fire*} style describes the same charge model and charge solver as the \textit{qeq/dynamic} style, but employs a FIRE minimization algorithm to solve for equilibrium charges. Keyword \textit{qdamp} can be used to change the damping factor, while keyword \textit{qstep} can be used to change the time step size.

Note that \textit{qeq/point}, \textit{qeq/shielded}, and \textit{qeq/slater} describe different charge models, whereas the matrix inversion method and the extended Lagrangian method (\textit{qeq/dynamic} and \textit{qeq/fire}) are different solvers.

Note that \textit{qeq/point}, \textit{qeq/dynamic} and \textit{qeq/fire} styles all describe charges as point charges that interact through \(1/r\) relationship, but solve partial charges on atoms using different solvers. These three styles should yield comparable results if the QEq parameters and \textit{Nevery}, \textit{cutoff}, and \textit{tolerance} are the same. Style \textit{qeq/point} is typically faster, \textit{qeq/dynamic} scales better on larger sizes, and \textit{qeq/fire} is faster than \textit{qeq/dynamic}.

\textbf{Note:} To avoid the evaluation of the derivative of charge with respect to position, which is typically ill-defined, the system should have a zero net charge.

\textbf{Note:} Developing QEq parameters (chi, eta, gamma, zeta, and qcore) is non-trivial. Charges on atoms are not guaranteed to equilibrate with arbitrary choices of these parameters. We do not develop these QEq parameters. See the examples/qeq directory for some examples.
18.150.4 Restart, fix_modify, output, run start/stop, minimize info

No information about these fixes is written to binary restart files. No global scalar or vector or per-atom quantities are stored by these fixes for access by various output commands. No parameter of these fixes can be used with the start/stop keywords of the run command.
These fixes are invoked during energy minimization.

18.150.5 Restrictions

These fixes are part of the QEQ package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

- zero or more keyword/value pairs may be appended
- keyword = file
file value = filename
filename = name of file to write QEQ equilibration info to

18.151.2 Examples

fix 1 surface qeq/comb 10 0.0001

18.151.3 Description

Perform charge equilibration (QeQ) in conjunction with the COMB (Charge-Optimized Many-Body) potential as described in (COMB_1) and (COMB_2). It performs the charge equilibration portion of the calculation using the so-called QEq method, whereby the charge on each atom is adjusted to minimize the energy of the system. This fix can only be used with the COMB potential; see the fix qeq/reax command for a QeQ calculation that can be used with any potential.

Only charges on the atoms in the specified group are equilibrated. The fix relies on the pair style (COMB in this case) to calculate the per-atom electronegativity (effective force on the charges). An electronegativity equalization calculation (or QEq) is performed in an iterative fashion, which in parallel requires communication at each iteration for processors to exchange charge information about nearby atoms with each other. See Rappe_and_Goddard and Rick_and_Stuart for details.

During a run, charge equilibration is performed every Nevery time steps. Charge equilibration is also always enforced on the first step of each run. The precision argument controls the tolerance for the difference in electronegativity for all atoms during charge equilibration. Precision is a trade-off between the cost of performing charge equilibration (more iterations) and accuracy.

If the file keyword is used, then information about each equilibration calculation is written to the specified file.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

18.151.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is performing charge equilibration. Default is the outermost level.

This fix produces a per-atom vector which can be accessed by various output commands. The vector stores the gradient of the charge on each atom. The per-atom values be accessed on any timestep.

No parameter of this fix can be used with the start/stop keywords of the run command.

This fix can be invoked during energy minimization.
18.151.5 Restrictions

This fix command currently only supports *pair style *comb*.

18.151.6 Related commands

*pair_style comb*

18.151.7 Default

```plaintext
fix ID group-ID qeq/reax Nevery cutlo cuthi tolerance params args
```

- ID, group-ID are documented in *fix* command
- *qeq/reax* = style name of this fix command
- *Nevery* = perform QEq every this many steps
- *cutlo,cuthi* = lo and hi cutoff for Taper radius
- *tolerance* = precision to which charges will be equilibrated
- *params* = reax/c or a filename
- one or more keywords or keyword/value pairs may be appended

```plaintext
keyword = dual or maxiter
dual = process S and T matrix in parallel (only for qeq/reax/omp)
maxiter N = limit the number of iterations to N
```
18.152.2 Examples

```
fix 1 all qeq/reax 1 0.0 10.0 1.0e-6 reax/c
fix 1 all qeq/reax 1 0.0 10.0 1.0e-6 param.qeq maxiter 500
```

18.152.3 Description

Perform the charge equilibration (QEq) method as described in (Rappe and Goddard) and formulated in (Nakano). It is typically used in conjunction with the ReaxFF force field model as implemented in the `pair_style reax/c` command, but it can be used with any potential in LAMMPS, so long as it defines and uses charges on each atom. The `fix qeq/comb` command should be used to perform charge equilibration with the COMB potential. For more technical details about the charge equilibration performed by `fix qeq/reax`, see the (Aktulga) paper.

The QEq method minimizes the electrostatic energy of the system by adjusting the partial charge on individual atoms based on interactions with their neighbors. It requires some parameters for each atom type. If the `params` setting above is the word “reax/c”, then these are extracted from the `pair_style reax/c` command and the ReaxFF force field file it reads in. If a file name is specified for `params`, then the parameters are taken from the specified file and the file must contain one line for each atom type. The latter form must be used when performing QeQ with a non-ReaxFF potential. Each line should be formatted as follows:

```
itype chi eta gamma
```

where `itype` is the atom type from 1 to Ntypes, `chi` denotes the electronegativity in eV, `eta` denotes the self-Coulomb potential in eV, and `gamma` denotes the valence orbital exponent. Note that these 3 quantities are also in the ReaxFF potential file, except that `eta` is defined here as twice the `eta` value in the ReaxFF file. Note that unlike the rest of LAMMPS, the units of this fix are hard-coded to be Å, eV, and electronic charge.

The optional `dual` keyword allows to perform the optimization of the S and T matrices in parallel. This is only supported for the `qeq/reax/omp` style. Otherwise they are processed separately.

The optional `maxiter` keyword allows changing the max number of iterations in the linear solver. The default value is 200.

18.152.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. No global scalar or vector or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the `run` command.

This fix is invoked during energy minimization.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
18.152.5 Restrictions

This fix is part of the USER-REAXC package. It is only enabled if LAMMPS was built with that package. See the
Build package doc page for more info.

This fix does not correctly handle interactions involving multiple periodic images of the same atom. Hence, it should
not be used for periodic cell dimensions less than 10 angstroms.

18.152.6 Related commands

pair_style reax/c

18.152.7 Default

maxiter 200

18.153 fix qmmm command

18.153.1 Syntax

fix ID group-ID qmmm

- ID, group-ID are documented in fix command
- qmmm = style name of this fix command

18.153.2 Examples

fix 1 qmol qmmm

18.153.3 Description

This fix provides functionality to enable a quantum mechanics/molecular mechanics (QM/MM) coupling of LAMMPS
to a quantum mechanical code. The current implementation only supports an ONIOM style mechanical coupling to
the Quantum ESPRESSO plane wave DFT package. Electrostatic coupling is in preparation and the interface has been
written in a manner that coupling to other QM codes should be possible without changes to LAMMPS itself.

The interface code for this is in the lib/qmmm directory of the LAMMPS distribution and is being made available at
this early stage of development in order to encourage contributions for interfaces to other QM codes. This will allow
the LAMMPS side of the implementation to be adapted if necessary before being finalized.

Details about how to use this fix are currently documented in the description of the QM/MM interface code itself in
lib/qmmm/README.
18.153.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global scalar or vector or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.153.5 Restrictions

This fix is part of the USER-QMMM package. It is only enabled if LAMMPS was built with that package. It also requires building a library provided with LAMMPS. See the Build package doc page for more info.

The fix is only functional when LAMMPS is built as a library and linked with a compatible QM program and a QM/MM front end into a QM/MM executable. See the lib/qmmm/README file for details.

fix 2 all qtb temp 300 damp 1 seed 47508 f_max 120.0 N_f 100
```

18.154.3 Description

This command performs the quantum thermal bath scheme proposed by (Dammak) to include self-consistent quantum nuclear effects, when used in conjunction with the `fix nve` or `fix nph` commands.

Classical molecular dynamics simulation does not include any quantum nuclear effect. Quantum treatment of the vibrational modes will introduce zero point energy into the system, alter the energy power spectrum and bias the heat capacity from the classical limit. Missing all the quantum nuclear effects, classical MD cannot model systems at temperatures lower than their classical limits. This effect is especially important for materials with a large population of hydrogen atoms and thus higher classical limits.

The equation of motion implemented by this command follows a Langevin form:

$$m_i a_i = f_i + R_i - m_i \gamma v_i$$

Here $m_i, a_i, f_i, R_i, \gamma,$ and $v_i$ represent in this order mass, acceleration, force exerted by all other atoms, random force, frictional coefficient (the inverse of damping parameter `damp`), and velocity. The random force $R_i$ is “colored” so that any vibrational mode with frequency $\omega$ will have a temperature-sensitive energy $\theta(\omega,T)$ which resembles the energy expectation for a quantum harmonic oscillator with the same natural frequency:

$$\theta(\omega,T) = \frac{\hbar}{2} + \hbar \omega \left[ \exp\left( \frac{\hbar \omega}{k_B T} \right) - 1 \right]^{-1}$$

To efficiently generate the random forces, we employ the method of (Barrat), that circumvents the need to generate all random forces for all times before the simulation. The memory requirement of this approach is less demanding and independent of the simulation duration. Since the total random force $R_{tot}$ does not necessarily vanish for a finite number of atoms, $R_i$ is replaced by $R_i - R_{tot}/N_{tot}$ to avoid collective motion of the system.

The `temp` parameter sets the target quantum temperature. LAMMPS will still have an output temperature in its thermo style. That is the instantaneous classical temperature $T^{cl}$ derived from the atom velocities at thermal equilibrium. A non-zero $T^{cl}$ will be present even when the quantum temperature approaches zero. This is associated with zero-point energy at low temperatures.

$$T^{cl} = \frac{\sum m_i v_i^2}{3Nk_B}$$

The `damp` parameter is specified in time units, and it equals the inverse of the frictional coefficient $\gamma$. $\gamma$ should be as small as possible but slightly larger than the timescale of anharmonic coupling in the system which is about 10 ps to 100 ps. When $\gamma$ is too large, it gives an energy spectrum that differs from the desired Bose-Einstein spectrum. When $\gamma$ is too small, the quantum thermal bath coupling to the system will be less significant than anharmonic effects, reducing to a classical limit. We find that setting $\gamma$ between 5 THz and 1 THz could be appropriate depending on the system.

The random number `seed` is a positive integer used to initiate a Marsaglia random number generator. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.
The \( f_{\text{max}} \) parameter truncate the noise frequency domain so that vibrational modes with frequencies higher than \( f_{\text{max}} \) will not be modulated. If we denote \( \Delta t \) as the time interval for the MD integration, \( f_{\text{max}} \) is always reset by the code to make \( \alpha = (\text{int})(2f_{\text{max}} \Delta t)^{-1} \) a positive integer and print out relative information. An appropriate value for the cutoff frequency \( f_{\text{max}} \) would be around 2~3 \( f_D \), where \( f_D \) is the Debye frequency.

The \( N_f \) parameter is the frequency grid size, the number of points from 0 to \( f_{\text{max}} \) in the frequency domain that will be sampled. \( 3*2N_f \) per-atom random numbers are required in the random force generation and there could be as many atoms as in the whole simulation that can migrate into every individual processor. A larger \( N_f \) provides a more accurate sampling of the spectrum while consumes more memory. With fixed \( f_{\text{max}} \) and \( \gamma \), \( N_f \) should be big enough to converge the classical temperature \( T^{cl} \) as a function of target quantum bath temperature. Memory usage per processor could be from 10 to 100 Mbytes.

**Note:** Unlike the \texttt{fix nvt} command which performs Nose/Hoover thermostatting AND time integration, this fix does NOT perform time integration. It only modifies forces to a colored thermostat. Thus you must use a separate time integration fix, like \texttt{fix nve} or \texttt{fix nph} to actually update the velocities and positions of atoms (as shown in the examples). Likewise, this fix should not normally be used with other fixes or commands that also specify system temperatures, e.g. \texttt{fix nvt} and \texttt{fix temp/rescale}.

### 18.154.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to \textit{binary restart files}. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix. However, in a statistical sense, a restarted simulation should produce similar behaviors of the system.

This fix is not invoked during energy minimization.

### 18.154.5 Restrictions

This fix style is part of the USER-QTB package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

18.155.2 Examples

```plaintext
fix 1 all reax/c/bonds 100 bonds.reaxc
```

18.155.3 Description

Write out the bond information computed by the ReaxFF potential specified by pair_style reax/c in the exact same format as the original stand-alone ReaxFF code of Adri van Duin. The bond information is written to filename on timesteps that are multiples of Nevery, including timestep 0. For time-averaged chemical species analysis, please see the fix reaxc/c/species command.

The specified group-ID is ignored by this fix.

The format of the output file should be reasonably self-explanatory. The meaning of the column header abbreviations is as follows:

- id = atom id
- type = atom type
- nb = number of bonds
- id_1 = atom id of first bond
- id_nb = atom id of Nth bond
- mol = molecule id
- bo_1 = bond order of first bond
- bo_nb = bond order of Nth bond
- abo = atom bond order (sum of all bonds)
- nlp = number of lone pairs
- q = atomic charge

If the filename ends with “.gz”, the output file is written in gzipped format. A gzipped dump file will be about 3x smaller than the text version, but will also take longer to write.
18.155.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

18.155.5 Restrictions

The fix reax/c/bonds command requires that the pair_style reax/c is invoked. This fix is part of the USER-REAXC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

To write gzipped bond files, you must compile LAMMPS with the -DLAMMPS_GZIP option.

\text{posfreq} = \text{write position files every this many timestep} \\
\text{filepos} = \text{name of position output file}
\]

18.156.2 Examples

```plaintext
fix 1 all reax/c/species 10 10 100 species.out
fix 1 all reax/c/species 1 2 20 species.out cutoff 1 1 0.40 cutoff 1 2 0.55
fix 1 all reax/c/species 1 100 100 species.out element Au O H position 1000 AuOH.pos
```

18.156.3 Description

Write out the chemical species information computed by the ReaxFF potential specified by `pair_style reax/c`. Bond-order values (either averaged or instantaneous, depending on value of `Nrepeat`) are used to determine chemical bonds. Every `Nfreq` timesteps, chemical species information is written to `filename` as a two line output. The first line is a header containing labels. The second line consists of the following: timestep, total number of molecules, total number of distinct species, number of molecules of each species. In this context, "species" means a unique molecule. The chemical formula of each species is given in the first line.

If the filename ends with ".gz", the output file is written in gzipped format. A gzipped dump file will be about 3x smaller than the text version, but will also take longer to write.

Optional keyword `cutoff` can be assigned to change the minimum bond-order values used in identifying chemical bonds between pairs of atoms. Bond-order cutoffs should be carefully chosen, as bond-order cutoffs that are too small may include too many bonds (which will result in an error), while cutoffs that are too large will result in fragmented molecules. The default cutoff of 0.3 usually gives good results.

The optional keyword `element` can be used to specify the chemical symbol printed for each LAMMPS atom type. The number of symbols must match the number of LAMMPS atom types and each symbol must consist of 1 or 2 alphanumeric characters. Normally, these symbols should be chosen to match the chemical identity of each LAMMPS atom type, as specified using the `reax/c pair_coeff` command and the ReaxFF force field file.

The optional keyword `position` writes center-of-mass positions of each identified molecules to file `filepos` every `posfreq` timesteps. The first line contains information on timestep, total number of molecules, total number of distinct species, and box dimensions. The second line is a header containing labels. From the third line downward, each molecule writes a line of output containing the following information: molecule ID, number of atoms in this molecule, chemical formula, total charge, and center-of-mass xyz positions of this molecule. The xyz positions are in fractional coordinates relative to the box dimensions.

For the keyword `position`, the `filepos` is the name of the output file. It can contain the wildcard character "*". If the "*" character appears in `filepos`, then one file per snapshot is written at `posfreq` and the "*" character is replaced with the timestep value. For example, `AuO.pos.*` becomes `AuO.pos.0`, `AuO.pos.1000`, etc.
The `Nevery`, `Nrepeat`, and `Nfreq` arguments specify on what timesteps the bond-order values are sampled to get the average bond order. The species analysis is performed using the average bond-order on timesteps that are a multiple of `Nfreq`. The average is over `Nrepeat` bond-order samples, computed in the preceding portion of the simulation every `Nevery` timesteps. `Nfreq` must be a multiple of `Nevery` and `Nevery` must be non-zero even if `Nrepeat` is 1. Also, the timesteps contributing to the average bond-order cannot overlap, i.e. `Nrepeat*Nevery` can not exceed `Nfreq`.

For example, if `Nevery=2`, `Nrepeat=6`, and `Nfreq=100`, then bond-order values on timesteps 90,92,94,96,98,100 will be used to compute the average bond-order for the species analysis output on timestep 100.

### 18.156.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix.

This fix computes both a global vector of length 2 and a per-atom vector, either of which can be accessed by various `output commands`. The values in the global vector are “intensive”.

The 2 values in the global vector are as follows:

- 1 = total number of molecules
- 2 = total number of distinct species

The per-atom vector stores the molecule ID for each atom as identified by the fix. If an atom is not in a molecule, its ID will be 0. For atoms in the same molecule, the molecule ID for all of them will be the same and will be equal to the smallest atom ID of any atom in the molecule.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 18.156.5 Restrictions

The “fix reax/c/species” currently only works with `pair_style reax/c` and it requires that the `pair_style reax/c` be invoked. This fix is part of the USER-REAXC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

To write gzipped species files, you must compile LAMMPS with the `-DLAMMPS_GZIP` option.

It should be possible to extend it to other reactive pair_styles (such as `rebo`, `airebo`, `comb`, and `bop`), but this has not yet been done.
18.156.6 Related commands

pair_style reax/c, fix reax/c/bonds

18.156.7 Default

The default values for bond-order cutoffs are 0.3 for all I-J pairs. The default element symbols are C, H, O, N. Position files are not written by default.

18.157 fix recenter command

18.157.1 Syntax

fix ID group-ID recenter x y z keyword value ...  

- ID, group-ID are documented in fix command
- recenter = style name of this fix command
- x,y,z = constrain center-of-mass to these coords (distance units), any coord can also be NULL or INIT (see below)
- zero or more keyword/value pairs may be appended
- keyword = shift or units  
  shift value = group-ID
  group-ID = group of atoms whose coords are shifted
  units value = box or lattice or fraction

18.157.2 Examples

fix 1 all recenter 0.0 0.5 0.0
fix 1 all recenter INIT INIT NULL
fix 1 all recenter INIT 0.0 0.0 units box

18.157.3 Description

Constrain the center-of-mass position of a group of atoms by adjusting the coordinates of the atoms every timestep. This is simply a small shift that does not alter the dynamics of the system or change the relative coordinates of any pair of atoms in the group. This can be used to insure the entire collection of atoms (or a portion of them) do not drift during the simulation due to random perturbations (e.g. fix langevin thermostating).

Distance units for the x,y,z values are determined by the setting of the units keyword, as discussed below. One or more x,y,z values can also be specified as NULL, which means exclude that dimension from this operation. Or it can be specified as INIT which means to constrain the center-of-mass to its initial value at the beginning of the run.

The center-of-mass (COM) is computed for the group specified by the fix. If the current COM is different than the specified x,y,z, then a group of atoms has their coordinates shifted by the difference. By default the shifted group is also the group specified by the fix. A different group can be shifted by using the shift keyword. For example, the COM could be computed on a protein to keep it in the center of the simulation box. But the entire system (protein + water) could be shifted.
If the `units` keyword is set to `box`, then the distance units of x,y,z are defined by the `units` command - e.g. Angstroms for `real` units. A `lattice` value means the distance units are in lattice spacings. The `lattice` command must have been previously used to define the lattice spacing. A `fraction` value means a fractional distance between the lo/hi box boundaries, e.g. 0.5 = middle of the box. The default is to use lattice units.

Note that the `velocity` command can be used to create velocities with zero aggregate linear and/or angular momentum.

**Note**: This fix performs its operations at the same point in the timestep as other time integration fixes, such as `fix nve`, `fix nvt`, or `fix npt`. Thus fix recenter should normally be the last such fix specified in the input script, since the adjustments it makes to atom coordinates should come after the changes made by time integration. LAMMPS will warn you if your fixes are not ordered this way.

**Note**: If you use this fix on a small group of atoms (e.g. a molecule in solvent) without using the `shift` keyword to adjust the positions of all atoms in the system, then the results can be unpredictable. For example, if the molecule is pushed consistently in one direction by a flowing solvent, its velocity will increase. But its coordinates will be re-centered, meaning it is moved back towards the force. Thus over time, the velocity and effective temperature of the molecule could become very large, though it won’t actually be moving due to the re-centering. If you are thermostating the entire system, then the solvent would be cooled to compensate. A better solution for this simulation scenario is to use the `fix spring` command to tether the molecule in place.

### 18.157.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to `binary restart files`. None of the `fix_modify` options are relevant to this fix.

This fix computes a global scalar which can be accessed by various `output commands`. The scalar is the distance the group is moved by fix recenter.

This fix also computes global 3-vector which can be accessed by various `output commands`. The 3 quantities in the vector are xyz components of displacement applied to the group of atoms by the fix.

The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during `energy minimization`.

### 18.157.5 Restrictions

This fix should not be used with an x,y,z setting that causes a large shift in the system on the first timestep, due to the requested COM being very different from the initial COM. This could cause atoms to be lost, especially in parallel. Instead, use the `displace_atoms` command, which can be used to move atoms a large distance.

### 18.157.6 Related commands

fix holdem all restrain bond 45 48 2000.0 2000.0 2.75 dihedral 1 2 3 4 2000.0 2000.0
fix texas_holdem all restrain dihedral 1 2 3 4 0.0 2000.0 120.0 dihedral 1 2 3 5 0.0
   -2000.0 -120.0 dihedral 1 2 3 6 0.0 2000.0 0.0
```

18.158.3 Description

Restrain the motion of the specified sets of atoms by making them part of a bond or angle or dihedral interaction whose strength can vary over time during a simulation. This is functionally similar to creating a bond or angle or dihedral for the same atoms in a data file, as specified by the `read_data` command, albeit with a time-varying pre-factor coefficient, and except for exclusion rules, as explained below.

For the purpose of force field parameter-fitting or mapping a molecular potential energy surface, this fix reduces the hassle and risk associated with modifying data files. In other words, use this fix to temporarily force a molecule to adopt a particular conformation. To create a permanent bond or angle or dihedral, you should modify the data file.

Note: Adding a bond/angle/dihedral with this command does not apply the exclusion rules and weighting factors specified by the `special_bonds` command to atoms in the restraint that are now bonded (1-2,1-3,1-4 neighbors) as a result. If they are close enough to interact in a `pair_style` sense (non-bonded interaction), then the bond/angle/dihedral restraint interaction will simply be superposed on top of that interaction.

The group-ID specified by this fix is ignored.

The second example above applies a restraint to hold the dihedral angle formed by atoms 1, 2, 3, and 4 near 120 degrees using a constant restraint coefficient. The fourth example applies similar restraints to multiple dihedral angles using a restraint coefficient that increases from 0.0 to 2000.0 over the course of the run.

Note: Adding a force to atoms implies a change in their potential energy as they move due to the applied force field. For dynamics via the `run` command, this energy can be added to the system’s potential energy for thermodynamic output (see below). For energy minimization via the `minimize` command, this energy must be added to the system’s potential energy to formulate a self-consistent minimization problem (see below).

In order for a restraint to be effective, the restraint force must typically be significantly larger than the forces associated with conventional force field terms. If the restraint is applied during a dynamics run (as opposed to during an energy minimization), a large restraint coefficient can significantly reduce the stable timestep size, especially if the atoms are initially far from the preferred conformation. You may need to experiment to determine what value of $K$ works best for a given application.

For the case of finding a minimum energy structure for a single molecule with particular restraints (e.g. for fitting force field parameters or constructing a potential energy surface), commands such as the following may be useful:

```
# minimize molecule energy with restraints
velocity all create 600.0 8675309 mom yes rot yes dist gaussian
fix NVE all nve
fix TFIX all langevin 600.0 0.0 100 24601
fix REST all restrain dihedral 2 1 3 8 0.0 5000.0 ${angle1} dihedral 3 1 2 9 0.0 5000.0
   -0.0 ${angle2}
```

(continues on next page)
The **bond** keyword applies a bond restraint to the specified atoms using the same functional form used by the **bond_style harmonic** command. The potential associated with the restraint is

\[ E = K(r - r_0)^2 \]

with the following coefficients:

- \( K \) (energy/distance^2)
- \( r_0 \) (distance)

\( K \) and \( r_0 \) are specified with the fix. Note that the usual 1/2 factor is included in \( K \).

The **lbound** keyword applies a lower bound bond restraint to the specified atoms using the same functional form used by the **bond_style harmonic** command if the distance between the atoms is smaller than the equilibrium bond distance and 0 otherwise. The potential associated with the restraint is

\[ \begin{align*}
E &= K(r - r_0)^2, \text{if } r < r_0 \\
E &= 0, \text{if } r \geq r_0
\end{align*} \]

with the following coefficients:

- \( K \) (energy/distance^2)
- \( r_0 \) (distance)

\( K \) and \( r_0 \) are specified with the fix. Note that the usual 1/2 factor is included in \( K \).

The **angle** keyword applies an angle restraint to the specified atoms using the same functional form used by the **angle_style harmonic** command. The potential associated with the restraint is

\[ E = K(\theta - \theta_0)^2 \]

with the following coefficients:

- \( K \) (energy)
- \( \theta_0 \) (degrees)
$K$ and $\theta_0$ are specified with the fix. $\theta_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence $K$ is effectively energy per radian^2. Note that the usual $1/2$ factor is included in $K$.

The *dihedral* keyword applies a dihedral restraint to the specified atoms using a simplified form of the function used by the *dihedral_style charmm* command. The potential associated with the restraint is

$$E = K[1 + \cos(n\phi - d)]$$

with the following coefficients:

- $K$ (energy)
- $n$ (multiplicity, $\geq 0$)
- $d$ (degrees) = $\phi_0 + 180$

$K$ and $\phi_0$ are specified with the fix. Note that the value of the dihedral multiplicity $n$ is set by default to 1. You can use the optional *mult* keyword to set it to a different positive integer. Also note that the energy will be a minimum when the current dihedral angle $\phi$ is equal to $\phi_0$.

**18.158.4 Restart, fix_modify, output, run start/stop, minimize info**

No information about this fix is written to *binary restart files*.

The *fix_modify energy* option is supported by this fix to add the potential energy associated with this fix to the system’s potential energy as part of *thermodynamic output*.

The *fix_modify respa* option is supported by this fix. This allows to set at which level of the *r-RESPA* integrator the fix is adding its forces. Default is the outermost level.

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the *fix_modify energy* option for this fix.

This fix computes a global scalar and a global vector of length 3, which can be accessed by various *output commands*. The scalar is the total potential energy for *all* the restraints as discussed above. The vector values are the sum of contributions to the following individual categories:

- 1 = bond energy
- 2 = angle energy
- 3 = dihedral energy

The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.
18.158.5 Restrictions

18.158.6 Related commands

none

18.158.7 Default

none

18.159 fix rhok command

18.159.1 Syntax

fix ID group-ID rhok nx ny nz K a

• ID, group-ID are documented in fix command
• nx, ny, nz = k-vector of collective density field
• K = spring constant of bias potential
• a = anchor point of bias potential

18.159.2 Examples

fix bias all rhok 16 0 0 4.0 16.0
fix 1 all npt temp 0.8 0.8 4.0 z 2.2 2.2 8.0
# output of 4 values from fix rhok: U_bias rho_k_RE rho_k_IM \|rho_k\|

18.159.3 Description

The fix applies a force to atoms given by the potential

\[ U = \frac{1}{2} K (|\rho_k| - a)^2 \]

\[ \rho_k = \sum_j \exp(-i\vec{k} \cdot \vec{r}_j)/\sqrt{N} \]

\[ \vec{k} = (2\pi n_x/L_x, 2\pi n_y/L_y, 2\pi n_z/L_z) \]

as described in \cite{Pedersen}.

This field, which biases configurations with long-range order, can be used to study crystal-liquid interfaces and determine melting temperatures \cite{Pedersen}.

An example of using the interface pinning method is located in the examples/USER/misc/rhok directory.
18.159.4 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.169.3 Description

Treat one or more sets of atoms as independent rigid bodies. This means that each timestep the total force and torque on each rigid body is computed as the sum of the forces and torques on its constituent particles. The coordinates, velocities, and orientations of the atoms in each body are then updated so that the body moves and rotates as a single entity. This is implemented by creating internal data structures for each rigid body and performing time integration on these data structures. Positions, velocities, and orientations of the constituent particles are regenerated from the rigid body data structures in every time step. This restricts which operations and fixes can be applied to rigid bodies. See below for a detailed discussion.

Examples of large rigid bodies are a colloidal particle, or portions of a biomolecule such as a protein.

Example of small rigid bodies are patchy nanoparticles, such as those modeled in this paper by Sharon Glotzer’s group, clumps of granular particles, lipid molecules consisting of one or more point dipoles connected to other spheroids or ellipsoids, irregular particles built from line segments (2d) or triangles (3d), and coarse-grain models of nano or colloidal particles consisting of a small number of constituent particles. Note that the fix shake command can also be used to rigidify small molecules of 2, 3, or 4 atoms, e.g. water molecules. That fix treats the constituent atoms as point masses.

These fixes also update the positions and velocities of the atoms in each rigid body via time integration, in the NVE, NVT, NPT, or NPH ensemble, as described below.

There are two main variants of this fix, fix rigid and fix rigid/small. The NVE/NVT/NPT/NHT versions belong to one of the two variants, as their style names indicate.

Note: Not all of the bodystyle options and keyword/value options are available for both the rigid and rigid/small variants. See details below.

The rigid styles are typically the best choice for a system with a small number of large rigid bodies, each of which can extend across the domain of many processors. It operates by creating a single global list of rigid bodies, which all processors contribute to. MPI_Allreduce operations are performed each timestep to sum the contributions from each processor to the force and torque on all the bodies. This operation will not scale well in parallel if large numbers of rigid bodies are simulated.

The rigid/small styles are typically best for a system with a large number of small rigid bodies. Each body is assigned to the atom closest to the geometrical center of the body. The fix operates using local lists of rigid bodies owned by each processor and information is exchanged and summed via local communication between neighboring processors when ghost atom info is accumulated.

Note: To use the rigid/small styles the ghost atom cutoff must be large enough to span the distance between the atom that owns the body and every other atom in the body. This distance value is printed out when the rigid bodies are defined. If the pair_style cutoff plus neighbor skin does not span this distance, then you should use the comm_modify cutoff command with a setting epsilon larger than the distance.

Which of the two variants is faster for a particular problem is hard to predict. The best way to decide is to perform a short test run. Both variants should give identical numerical answers for short runs. Long runs should give statistically similar results, but round-off differences may accumulate to produce divergent trajectories.

Note: You should not update the atoms in rigid bodies via other time-integration fixes (e.g. fix nve, fix nvt, fix npt, fix move), or you will have conflicting updates to positions and velocities resulting in unphysical behavior in most cases. When performing a hybrid simulation with some atoms in rigid bodies, and some not, a separate time integration fix like fix nve or fix nvt should be used for the non-rigid particles.
Note: These fixes are overkill if you simply want to hold a collection of atoms stationary or have them move with a constant velocity. A simpler way to hold atoms stationary is to not include those atoms in your time integration fix. E.g. use “fix 1 mobile nve” instead of “fix 1 all nve”, where “mobile” is the group of atoms that you want to move. You can move atoms with a constant velocity by assigning them an initial velocity (via the velocity command), setting the force on them to 0.0 (via the fix setforce command), and integrating them as usual (e.g. via the fix nve command).

Warning: The aggregate properties of each rigid body are calculated at the start of a simulation run and are maintained in internal data structures. The properties include the position and velocity of the center-of-mass of the body, its moments of inertia, and its angular momentum. This is done using the properties of the constituent atoms of the body at that point in time (or see the infile keyword option). Thereafter, changing these properties of individual atoms in the body will have no effect on a rigid body’s dynamics, unless they effect any computation of per-atom forces or torques. If the keyword reinit is set to yes (the default), the rigid body data structures will be recreated at the beginning of each run command; if the keyword reinit is set to no, the rigid body data structures will be built only at the very first run command and maintained for as long as the rigid fix is defined. For example, you might think you could displace the atoms in a body or add a large velocity to each atom in a body to make it move in a desired direction before a second run is performed, using the set or displace_atoms or velocity commands. But these commands will not affect the internal attributes of the body unless reinit is set to yes. With reinit set to no (or using the infile option, which implies reinit no) the position and velocity of individual atoms in the body will be reset when time integration starts again.

Each rigid body must have two or more atoms. An atom can belong to at most one rigid body. Which atoms are in which bodies can be defined via several options.

Note: With the rigid/small styles, which require that bodystyle be specified as molecule or custom, you can define a system that has no rigid bodies initially. This is useful when you are using the mol keyword in conjunction with another fix that is adding rigid bodies on-the-fly as molecules, such as fix deposit or fix pour.

For bodystyle single the entire fix group of atoms is treated as one rigid body. This option is only allowed for the rigid styles.

For bodystyle molecule, atoms are grouped into rigid bodies by their respective molecule IDs: each set of atoms in the fix group with the same molecule ID is treated as a different rigid body. This option is allowed for both the rigid and rigid/small styles. Note that atoms with a molecule ID = 0 will be treated as a single rigid body. For a system with atomic solvent (typically this is atoms with molecule ID = 0) surrounding rigid bodies, this may not be what you want. Thus you should be careful to use a fix group that only includes atoms you want to be part of rigid bodies.

Bodystyle custom is similar to bodystyle molecule except that it is more flexible in using other per-atom properties to define the sets of atoms that form rigid bodies. An integer vector defined by the fix property/atom command can be used. Or an atom-style or atomfile-style variable can be used; the floating-point value produced by the variable is rounded to an integer. As with bodystyle molecule, each set of atoms in the fix groups with the same integer value is treated as a different rigid body. Since fix property/atom vectors and atom-style variables produce values for all atoms, you should be careful to use a fix group that only includes atoms you want to be part of rigid bodies.

Note: To compute the initial center-of-mass position and other properties of each rigid body, the image flags for each atom in the body are used to “unwrap” the atom coordinates. Thus you must insure that these image flags are consistent so that the unwrapping creates a valid rigid body (one where the atoms are close together), particularly if the atoms in a single rigid body straddle a periodic boundary. This means the input data file or restart file must define the
image flags for each atom consistently or that you have used the *set* command to specify them correctly. If a dimension is non-periodic then the image flag of each atom must be 0 in that dimension, else an error is generated.

The *force* and *torque* keywords discussed next are only allowed for the *rigid* styles.

By default, each rigid body is acted on by other atoms which induce an external force and torque on its center of mass, causing it to translate and rotate. Components of the external center-of-mass force and torque can be turned off by the *force* and *torque* keywords. This may be useful if you wish a body to rotate but not translate, or vice versa, or if you wish it to rotate or translate continuously unaffected by interactions with other particles. Note that if you expect a rigid body not to move or rotate by using these keywords, you must insure its initial center-of-mass translational or angular velocity is 0.0. Otherwise the initial translational or angular momentum the body has will persist.

An xflag, yflag, or zflag set to *off* means turn off the component of force of torque in that dimension. A setting of *on* means turn on the component, which is the default. Which rigid body(s) the settings apply to is determined by the first argument of the *force* and *torque* keywords. It can be an integer M from 1 to Nbody, where Nbody is the number of rigid bodies defined. A wild-card asterisk can be used in place of, or in conjunction with, the M argument to set the flags for multiple rigid bodies. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of rigid bodies, then an asterisk with no numeric values means all bodies from 1 to N. A leading asterisk means all bodies from 1 to n (inclusive). A trailing asterisk means all bodies from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that you can use the *force* or *torque* keywords as many times as you like. If a particular rigid body has its component flags set multiple times, the settings from the final keyword are used.

Note: For computational efficiency, you may wish to turn off pairwise and bond interactions within each rigid body, as they no longer contribute to the motion. The *neigh_modify exclude* and *delete_bonds* commands are used to do this. If the rigid bodies have strongly overlapping atoms, you may need to turn off these interactions to avoid numerical problems due to large equal/opposite intra-body forces swamping the contribution of small inter-body forces.

For computational efficiency, you should typically define one fix rigid or fix rigid/small command which includes all the desired rigid bodies. LAMMPS will allow multiple rigid fixes to be defined, but it is more expensive.

The constituent particles within a rigid body can be point particles (the default in LAMMPS) or finite-size particles, such as spheres or ellipsoids or line segments or triangles. See the *atom_style sphere* and *ellipsoid* and *line* and *tri* commands for more details on these kinds of particles. Finite-size particles contribute differently to the moment of inertia of a rigid body than do point particles. Finite-size particles can also experience torque (e.g. due to *frictional granular interactions*) and have an orientation. These contributions are accounted for by these fixes.

Forces between particles within a body do not contribute to the external force or torque on the body. Thus for computational efficiency, you may wish to turn off pairwise and bond interactions between particles within each rigid body. The *neigh_modify exclude* and *delete_bonds* commands are used to do this. For finite-size particles this also means the particles can be highly overlapped when creating the rigid body.

The *rigid*, *rigid/nve*, *rigid/small*, and *rigid/small/nve* styles perform constant NVE time integration. They are referred to below as the 4 NVE rigid styles. The only difference is that the *rigid* and *rigid/small* styles use an integration technique based on Richardson iterations. The *rigid/nve* and *rigid/small/nve* styles uses the methods described in the paper by Miller, which are thought to provide better energy conservation than an iterative approach.

The *rigid/nvt* and *rigid/nvt/small* styles performs constant NVT integration using a Nose/Hoover thermostat with chains as described originally in (Hoover) and (Martyna), which thermostat both the translational and rotational degrees of freedom of the rigid bodies. They are referred to below as the 2 NVT rigid styles. The rigid-body algorithm used by *rigid/nvt* is described in the paper by Kamberaj.
The \textit{rigid/npt}, \textit{rigid/nph}, \textit{rigid/npt/small}, and \textit{rigid/nph/small} styles perform constant NPT or NPH integration using a Nose/Hoover barostat with chains. They are referred to below as the 4 NPT and NPH rigid styles. For the NPT case, the same Nose/Hoover thermostat is also used as with \textit{rigid/nvt} and \textit{rigid/nvt/small}.

The barostat parameters are specified using one or more of the \textit{iso}, \textit{aniso}, \textit{x}, \textit{y}, \textit{z} and \textit{couple} keywords. These keywords give you the ability to specify 3 diagonal components of the external stress tensor, and to couple these components together so that the dimensions they represent are varied together during a constant-pressure simulation. The effects of these keywords are similar to those defined in \textit{fix npt/nph}

\textbf{Note:} Currently the \textit{rigid/npt}, \textit{rigid/nph}, \textit{rigid/npt/small}, and \textit{rigid/nph/small} styles do not support triclinic (non-orthogonal) boxes.

The target pressures for each of the 6 components of the stress tensor can be specified independently via the \textit{x}, \textit{y}, \textit{z} keywords, which correspond to the 3 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from \textit{Pstart} to \textit{Pstop}. If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the \textit{y} keyword is used, the \textit{y}-box length will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the \textit{fix deform} command.

For all barostat keywords, the \textit{Pdamp} parameter operates like the \textit{Tdamp} parameter, determining the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (e.g. \(\tau\) or fs or ps - see the \textit{units} command).

Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword \textit{dilate} is specified with a \textit{dilate-group-ID} for a group that represents a subset of the atoms. This can be useful, for example, to leave the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid. Another example is a system consisting of rigid bodies and point particles where the barostat is only coupled with the rigid bodies. This option should be used with care, since it can be unphysical to dilate some atoms and not others, because it can introduce large, instantaneous displacements between a pair of atoms (one dilated, one not) that are far from the dilation origin.

The \textit{couple} keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, \textit{xz} means the \textit{Pxz} and \textit{Pzz} components of the stress tensor are coupled. \textit{Xyz} means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The \textit{Pstart}, \textit{Pstop}, \textit{Pdamp} parameters for any coupled dimensions must be identical. \textit{Couple xyz} can be used for a 2d simulation; the \textit{z} dimension is simply ignored.

The \textit{iso} and \textit{aniso} keywords are simply shortcuts that are equivalent to specifying several other keywords together.

The keyword \textit{iso} means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “\textit{iso Pstart Pstop Pdamp}” is the same as specifying these 4 keywords:

\begin{verbatim}
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple xyz
\end{verbatim}

The keyword \textit{aniso} means \textit{x}, \textit{y}, and \textit{z} dimensions are controlled independently using the \textit{Pxx}, \textit{Pyy}, and \textit{Pzz} components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “\textit{aniso Pstart Pstop Pdamp}” is the same as specifying these 4 keywords:
The keyword/value option pairs are used in the following ways.

The `reinit` keyword determines, whether the rigid body properties are re-initialized between run commands. With the option `yes` (the default) this is done, with the option `no` this is not done. Turning off the re-initialization can be helpful to protect rigid bodies against unphysical manipulations between runs or when properties cannot be easily re-computed (e.g. when read from a file). When using the `infile` keyword, the `reinit` option is automatically set to `no`.

The `langevin` and `temp` and `tparam` keywords perform thermostatting of the rigid bodies, altering both their translational and rotational degrees of freedom. What is meant by “temperature” of a collection of rigid bodies and how it can be monitored via the `fix` output is discussed below.

The `langevin` keyword applies a Langevin thermostat to the constant NVE time integration performed by any of the 4 NVE rigid styles: `rigid`, `rigid/nve`, `rigid/small`, `rigid/small/nve`. It cannot be used with the 2 NVT rigid styles: `rigid/nvt`, `rigid/small/nvt`. The desired temperature at each timestep is a ramped value during the run from `Tstart` to `Tstop`. The `Tdamp` parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (\(\tau\) or fs or ps - see the `units` command). The random # seed must be a positive integer.

The way that Langevin thermostatting operates is explained on the `fix langevin` doc page. If you wish to simply viscously damp the rotational motion without thermostatting, you can set `Tstart` and `Tstop` to 0.0, which means only the viscous drag term in the Langevin thermostat will be applied. See the discussion on the `fix viscous` doc page for details.

**Note:** When the `langevin` keyword is used with fix rigid versus fix rigid/small, different dynamics will result for parallel runs. This is because of the way random numbers are used in the two cases. The dynamics for the two cases should be statistically similar, but will not be identical, even for a single timestep.

The `temp` and `tparam` keywords apply a Nose/Hoover thermostat to the NVT time integration performed by the 2 NVT rigid styles. They cannot be used with the 4 NVE rigid styles. The desired temperature at each timestep is a ramped value during the run from `Tstart` to `Tstop`. The `Tdamp` parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (\(\tau\) or fs or ps - see the `units` command).

Nose/Hoover chains are used in conjunction with this thermostat. The `tparam` keyword can optionally be used to change the chain settings used. `Tchain` is the number of thermostats in the Nose Hoover chain. This value, along with `Tdamp` can be varied to dampen undesirable oscillations in temperature that can occur in a simulation. As a rule of thumb, increasing the chain length should lead to smaller oscillations. The keyword `pchain` specifies the number of thermostats in the chain thermostatting the barostat degrees of freedom.

**Note:** There are alternate ways to thermostat a system of rigid bodies. You can use `fix langevin` to treat the individual particles in the rigid bodies as effectively immersed in an implicit solvent, e.g. a Brownian dynamics model. For hybrid systems with both rigid bodies and solvent particles, you can thermostat only the solvent particles that surround one or more rigid bodies by appropriate choice of groups in the compute and fix commands for temperature and thermostatting. The solvent interactions with the rigid bodies should then effectively thermostat the rigid body temperature as well without use of the Langevin or Nose/Hoover options associated with the fix rigid commands.
The *mol* keyword can only be used with the *rigid/small* styles. It must be used when other commands, such as *fix deposit* or *fix pour*, add rigid bodies on-the-fly during a simulation. You specify a *template-ID* previously defined using the *molecule* command, which reads a file that defines the molecule. You must use the same *template-ID* that the other fix which is adding rigid bodies uses. The coordinates, atom types, atom diameters, center-of-mass, and moments of inertia can be specified in the molecule file. See the *molecule* command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule, in which case the molecule command calculates the other quantities itself.

Note that these other fixes create new rigid bodies, in addition to those defined initially by this fix via the *bodystyle* setting.

Also note that when using the *mol* keyword, extra restart information about all rigid bodies is written out whenever a restart file is written out. See the NOTE in the next section for details.

The *infile* keyword allows a file of rigid body attributes to be read in from a file, rather than having LAMMPS compute them. There are 5 such attributes: the total mass of the rigid body, its center-of-mass position, its 6 moments of inertia, its center-of-mass velocity, and the 3 image flags of the center-of-mass position. For rigid bodies consisting of point particles or non-overlapping finite-size particles, LAMMPS can compute these values accurately. However, for rigid bodies consisting of finite-size particles which overlap each other, LAMMPS will ignore the overlaps when computing these 4 attributes. The amount of error this induces depends on the amount of overlap. To avoid this issue, the values can be pre-computed (e.g. using Monte Carlo integration).

The format of the file is as follows. Note that the file does not have to list attributes for every rigid body integrated by fix rigid. Only bodies which the file specifies will have their computed attributes overridden. The file can contain initial blank lines or comment lines starting with `#` which are ignored. The first non-blank, non-comment line should list \( N = \) the number of lines to follow. The \( N \) successive lines contain the following information:

```
ID1 masstotal xcm ycm zcm ixx iyy izz ixy ixz iyz vxcm vycm vzcm 1x 1y 1z ixcm iycm izcm
ID2 masstotal xcm ycm zcm ixx iyy izz ixy ixz iyz vxcm vycm vzcm 1x 1y 1z ixcm iycm izcm
... 
IDN masstotal xcm ycm zcm ixx iyy izz ixy ixz iyz vxcm vycm vzcm 1x 1y 1z ixcm iycm izcm
```

The rigid body IDs are all positive integers. For the *single* bodystyle, only an ID of 1 can be used. For the *group* bodystyle, IDs from 1 to \( N_g \) can be used where \( N_g \) is the number of specified groups. For the *molecule* bodystyle, use the molecule ID for the atoms in a specific rigid body as the rigid body ID.

The *masstotal* and center-of-mass coordinates \( (xcm,ycm,zcm) \) are self-explanatory. The center-of-mass should be consistent with what is calculated for the position of the rigid body with all its atoms unwrapped by their respective image flags. If this produces a center-of-mass that is outside the simulation box, LAMMPS wraps it back into the box.

The 6 moments of inertia \( (ixx,iyy,izz,ixy,ixz,ifyz) \) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally.

The \( (vxcm,vycm,vzcm) \) values are the velocity of the center of mass. The \( (lx,ly,lz) \) values are the angular momentum of the body. The \( (vxcm,vycm,vzcm) \) and \( (lx,ly,lz) \) values can simply be set to 0 if you wish the body to have no initial motion.

The \( (ixcm,iycm,izcm) \) values are the image flags of the center of mass of the body. For periodic dimensions, they specify which image of the simulation box the body is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as the rigid bodies cross periodic boundaries during the simulation.
Note: If you use the *infile* or *mol* keywords and write restart files during a simulation, then each time a restart file is written, the fix also write an auxiliary restart file with the name rfile.rigid, where “rfile” is the name of the restart file, e.g. tmp.restart.10000 and tmp.restart.10000.rigid. This auxiliary file is in the same format described above. Thus it can be used in a new input script that restarts the run and re-specifies a rigid fix using an *infile* keyword and the appropriate filename. Note that the auxiliary file will contain one line for every rigid body, even if the original file only listed a subset of the rigid bodies.

If you use a *temperature compute* with a group that includes particles in rigid bodies, the degrees-of-freedom removed by each rigid body are accounted for in the temperature (and pressure) computation, but only if the temperature group includes all the particles in a particular rigid body.

A 3d rigid body has 6 degrees of freedom (3 translational, 3 rotational), except for a collection of point particles lying on a straight line, which has only 5, e.g. a dimer. A 2d rigid body has 3 degrees of freedom (2 translational, 1 rotational).

Note: You may wish to explicitly subtract additional degrees-of-freedom if you use the *force* and *torque* keywords to eliminate certain motions of one or more rigid bodies. LAMMPS does not do this automatically.

The rigid body contribution to the pressure of the system (virial) is also accounted for by this fix.

If your simulation is a hybrid model with a mixture of rigid bodies and non-rigid particles (e.g. solvent) there are several ways these rigid fixes can be used in tandem with *fix nve*, *fix nvt*, *fix npt*, and *fix nph*.

If you wish to perform NVE dynamics (no thermostatting or barostatting), you can use one of the 4 NVE rigid styles to integrate the rigid bodies, and *fix nve* to integrate the non-rigid particles.

If you wish to perform NVT dynamics (thermostatting, but no barostatting), you can use one of the 2 NVT rigid styles for the rigid bodies, and any thermostatting fix for the non-rigid particles (*fix nvt*, *fix langevin*, *fix temp/berendsen*). You can also use one of the 4 NVE rigid styles for the rigid bodies and thermostat them using *fix langevin* on the group that contains all the particles in the rigid bodies. The net force added by *fix langevin* to each rigid body effectively thermostats its translational center-of-mass motion. Not sure how well it does at thermostatting its rotational motion.

If you wish to perform NPT or NPH dynamics (barostatting), you cannot use both *fix npt* and the NPT or NPH rigid styles. This is because there can only be one fix which monitors the global pressure and changes the simulation box dimensions. So you have 3 choices:

- Use one of the 4 NPT or NPH styles for the rigid bodies. Use the *dilate* all option so that it will dilate the positions of the non-rigid particles as well. Use *fix nvt* (or any other thermostat) for the non-rigid particles.
- Use *fix npt* for the group of non-rigid particles. Use the *dilate* all option so that it will dilate the center-of-mass positions of the rigid bodies as well. Use one of the 4 NVE or 2 NVT rigid styles for the rigid bodies.
- Use *fix press/berendsen* to compute the pressure and change the box dimensions. Use one of the 4 NVE or 2 NVT rigid styles for the rigid bodies. Use *fix nvt* (or any other thermostat) for the non-rigid particles.

In all case, the rigid bodies and non-rigid particles both contribute to the global pressure and the box is scaled the same by any of the barostatting fixes.

You could even use the second and third options for a non-hybrid simulation consisting of only rigid bodies, assuming you give *fix npt* an empty group, though it’s an odd thing to do. The barostatting fixes (*fix npt* and *fix press/berendsen*) will monitor the pressure and change the box dimensions, but not time integrate any particles. The integration of the rigid bodies will be performed by *fix rigid/nvt*.
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

18.169.4 Restart, fix_modify, output, run start/stop, minimize info

No information about the 4 NVE rigid styles is written to binary restart files. The exception is if the `infile` or `mol` keyword is used, in which case an auxiliary file is written out with rigid body information each time a restart file is written, as explained above for the `infile` keyword. For the 2 NVT rigid styles, the state of the Nose/Hoover thermostat is written to binary restart files. Ditto for the 4 NPT and NPH rigid styles, and the state of the Nose/Hoover barostat. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The `fix_modify energy` option is supported by the 6 NVT, NPT, NPH rigid styles to add the energy change induced by the thermostating to the system’s potential energy as part of thermodynamic output.

The `fix_modify virial` option is supported by this fix to add the contribution due to keeping the objects rigid to the system’s virial as part of thermodynamic output. The default is `virial yes`.

The `fix_modify temp` and `press` options are supported by the 4 NPT and NPH rigid styles to change the computes used to calculate the instantaneous pressure tensor. Note that the 2 NVT rigid fixes do not use any external compute to compute instantaneous temperature.

The `fix_modify bodyforces` option is supported by all rigid styles to set whether per-body forces and torques are computed early or late in a timestep, i.e. at the post-force stage or at the final-integrate stage or the timestep, respectively.

The 2 NVE rigid fixes compute a global scalar which can be accessed by various output commands. The scalar value calculated by these fixes is “intensive”. The scalar is the current temperature of the collection of rigid bodies. This is averaged over all rigid bodies and their translational and rotational degrees of freedom. The translational energy of a rigid body is $\frac{1}{2} m v^2$, where $m = \text{total mass of the body}$ and $v = \text{the velocity of its center of mass}$. The rotational energy of a rigid body is $\frac{1}{2} I w^2$, where $I = \text{the moment of inertia tensor of the body}$ and $w = \text{its angular velocity}$. Degrees of freedom constrained by the `force` and `torque` keywords are removed from this calculation, but only for the rigid and rigid/nve fixes.

The 6 NVT, NPT, NPH rigid fixes compute a global scalar which can be accessed by various output commands. The scalar value calculated by these fixes is “extensive”. The scalar is the cumulative energy change due to the thermostating and barostatting the fix performs.

All of the rigid styles (not the rigid/small styles) compute a global array of values which can be accessed by various output commands. Similar information about the bodies defined by the rigid/small styles can be accessed via the compute rigid/local command.

The number of rows in the array is equal to the number of rigid bodies. The number of columns is 15. Thus for each rigid body, 15 values are stored: the xyz coords of the center of mass (COM), the xyz components of the COM velocity, the xyz components of the force acting on the COM, the xyz components of the torque acting on the COM, and the xyz image flags of the COM.

The center of mass (COM) for each body is similar to unwrapped coordinates written to a dump file. It will always be inside (or slightly outside) the simulation box. The image flags have the same meaning as image flags for atom
positions (see the “dump” command). This means you can calculate the unwrapped COM by applying the image flags to the COM, the same as when unwrapped coordinates are written to a dump file.

The force and torque values in the array are not affected by the *force* and *torque* keywords in the fix rigid command; they reflect values before any changes are made by those keywords.

The ordering of the rigid bodies (by row in the array) is as follows. For the *single* keyword there is just one rigid body. For the *molecule* keyword, the bodies are ordered by ascending molecule ID. For the *group* keyword, the list of group IDs determines the ordering of bodies.

The array values calculated by these fixes are “intensive”, meaning they are independent of the number of atoms in the simulation.

No parameter of these fixes can be used with the *start/stop* keywords of the *run* command. These fixes are not invoked during *energy minimization*.

### 18.169.5 Restrictions

These fixes are all part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

Assigning a temperature via the *velocity create* command to a system with rigid bodies may not have the desired outcome for two reasons. First, the velocity command can be invoked before the rigid-body fix is invoked or initialized and the number of adjusted degrees of freedom (DOFs) is known. Thus it is not possible to compute the target temperature correctly. Second, the assigned velocities may be partially canceled when constraints are first enforced, leading to a different temperature than desired. A workaround for this is to perform a *run 0* command, which insures all DOFs are accounted for properly, and then rescale the temperature to the desired value before performing a simulation. For example:

```
velocity all create 300.0 12345
run 0  # temperature may not be 300K
velocity all scale 300.0  # now it should be
```

### 18.169.6 Related commands

*delete_bonds, neigh_modify exclude, fix shake*

### 18.169.7 Default

The option defaults are *force* *on on on* and *torque* *on on on*, meaning all rigid bodies are acted on by center-of-mass force and torque. Also Tchain = Pchain = 10, Titer = 1, Torder = 3, reinit = yes.

---

18.170 fix rigid/meso command

18.170.1 Syntax

```bash
fix ID group-ID rigid/meso bodystyle args keyword values ...
```

- ID, group-ID are documented in `fix` command
- rigid/meso = style name of this fix command
- bodystyle = `single` or `molecule` or `group`
  - `single` args = none
  - `molecule` args = none
  - `custom` args = `i_propname` or `v_varname`
    - `i_propname` = an integer property defined via `fix property/atom`
    - `v_varname` = an atom-style or atomfile-style variable
  - `group` args = `N` `groupID1` `groupID2` ...
    - `N` = # of groups
    - `groupID1`, `groupID2`, ... = list of `N` group IDs
- zero or more keyword/value pairs may be appended
- keyword = `reinit` or `force` or `torque` or `infile`
  - `reinit` = `yes` or `no`
  - `force` values = `M` `xflag` `yflag` `zflag`
    - `M` = which rigid body from 1-Nbody (see asterisk form below)
    - `xflag`, `yflag`, `zflag` = off/on if component of center-of-mass force is active
  - `torque` values = `M` `xflag` `yflag` `zflag`
    - `M` = which rigid body from 1-Nbody (see asterisk form below)
    - `xflag`, `yflag`, `zflag` = off/on if component of center-of-mass torque is active
  - `infile` filename
    - `filename` = file with per-body values of mass, center-of-mass, moments of inertia
18.170.2 Examples

```

fix 2 spheres rigid/meso group 3 sphere1 sphere2 sphere3 torque off off off
```

18.170.3 Description

Treat one or more sets of mesoscopic SPH/SDPD particles as independent rigid bodies. This means that each timestep the total force and torque on each rigid body is computed as the sum of the forces and torques on its constituent particles. The coordinates and velocities of the particles in each body are then updated so that the body moves and rotates as a single entity using the methods described in the paper by (Miller). Density and internal energy of the particles will also be updated. This is implemented by creating internal data structures for each rigid body and performing time integration on these data structures. Positions and velocities of the constituent particles are regenerated from the rigid body data structures in every time step. This restricts which operations and fixes can be applied to rigid bodies. See below for a detailed discussion.

The operation of this fix is exactly like that described by the `fix rigid/nve` command, except that particles’ density, internal energy and extrapolated velocity are also updated.

**Note:** You should not update the particles in rigid bodies via other time-integration fixes (e.g. `fix sph`, `fix sph/stationary`), or you will have conflicting updates to positions and velocities resulting in unphysical behavior in most cases. When performing a hybrid simulation with some atoms in rigid bodies, and some not, a separate time integration fix like `fix sph` should be used for the non-rigid particles.

**Note:** These fixes are overkill if you simply want to hold a collection of particles stationary or have them move with a constant velocity. To hold particles stationary use `fix sph/stationary` instead. If you would like to move particles with a constant velocity use `fix meso/move`.

**Warning:** The aggregate properties of each rigid body are calculated at the start of a simulation run and are maintained in internal data structures. The properties include the position and velocity of the center-of-mass of the body, its moments of inertia, and its angular momentum. This is done using the properties of the constituent particles of the body at that point in time (or see the `infile` keyword option). Thereafter, changing these properties of individual particles in the body will have no effect on a rigid body’s dynamics, unless they effect any computation of per-particle forces or torques. If the keyword `reinit` is set to `yes` (the default), the rigid body data structures will be recreated at the beginning of each `run` command; if the keyword `reinit` is set to `no`, the rigid body data structures will be built only at the very first `run` command and maintained for as long as the rigid fix is defined. For example, you might think you could displace the particles in a body or add a large velocity to each particle in a body to make it move in a desired direction before a second run is performed, using the `set` or `displace_atoms` or `velocity` commands. But these commands will not affect the internal attributes of the body unless `reinit` is set to `yes`. With `reinit set to no` (or using the `infile` option, which implies `reinit no`) the position and velocity of individual particles in the body will be reset when time integration starts again.

Each rigid body must have two or more particles. A particle can belong to at most one rigid body. Which particles are in which bodies can be defined via several options.
For bodystyle *single* the entire fix group of particles is treated as one rigid body.

For bodystyle *molecule*, particles are grouped into rigid bodies by their respective molecule IDs: each set of particles in the fix group with the same molecule ID is treated as a different rigid body. Note that particles with a molecule ID = 0 will be treated as a single rigid body. For a system with solvent (typically this is particles with molecule ID = 0) surrounding rigid bodies, this may not be what you want. Thus you should be careful to use a fix group that only includes particles you want to be part of rigid bodies.

Bodystyle *custom* is similar to bodystyle *molecule* except that it is more flexible in using other per-atom properties to define the sets of particles that form rigid bodies. An integer vector defined by the fix property/atom command can be used. Or an atom-style or atomfile-style variable can be used; the floating-point value produced by the variable is rounded to an integer. As with bodystyle *molecule*, each set of particles in the fix groups with the same integer value is treated as a different rigid body. Since fix property/atom vectors and atom-style variables produce values for all particles, you should be careful to use a fix group that only includes particles you want to be part of rigid bodies.

For bodystyle *group*, each of the listed groups is treated as a separate rigid body. Only particles that are also in the fix group are included in each rigid body.

**Note:** To compute the initial center-of-mass position and other properties of each rigid body, the image flags for each particle in the body are used to “unwrap” the particle coordinates. Thus you must insure that these image flags are consistent so that the unwrapping creates a valid rigid body (one where the particles are close together), particularly if the particles in a single rigid body straddle a periodic boundary. This means the input data file or restart file must define the image flags for each particle consistently or that you have used the set command to specify them correctly. If a dimension is non-periodic then the image flag of each particle must be 0 in that dimension, else an error is generated.

By default, each rigid body is acted on by other particles which induce an external force and torque on its center of mass, causing it to translate and rotate. Components of the external center-of-mass force and torque can be turned off by the force and torque keywords. This may be useful if you wish a body to rotate but not translate, or vice versa, or if you wish it to rotate or translate continuously unaffected by interactions with other particles. Note that if you expect a rigid body not to move or rotate by using these keywords, you must insure its initial center-of-mass translational or angular velocity is 0.0. Otherwise the initial translational or angular momentum, the body has, will persist.

An xflag, yflag, or zflag set to off means turn off the component of force or torque in that dimension. A setting of on means turn on the component, which is the default. Which rigid body(s) the settings apply to is determined by the first argument of the force and torque keywords. It can be an integer M from 1 to Nbody, where Nbody is the number of rigid bodies defined. A wild-card asterisk can be used in place of, or in conjunction with, the M argument to set the flags for multiple rigid bodies. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the number of rigid bodies, then an asterisk with no numeric values means all bodies from 1 to N. A leading asterisk means all bodies from 1 to n (inclusive). A trailing asterisk means all bodies from n to N (inclusive). A middle asterisk means all bodies from m to n (inclusive). Note that you can use the force or torque keywords as many times as you like. If a particular rigid body has its component flags set multiple times, the settings from the final keyword are used.

For computational efficiency, you should typically define one fix rigid/meso command which includes all the desired rigid bodies. LAMMPS will allow multiple rigid/meso fixes to be defined, but it is more expensive.

The keyword/value option pairs are used in the following ways.

The reinit keyword determines, whether the rigid body properties are re-initialized between run commands. With the option yes (the default) this is done, with the option no this is not done. Turning off the re-initialization can be helpful to protect rigid bodies against unphysical manipulations between runs or when properties cannot be easily re-computed (e.g. when read from a file). When using the infile keyword, the reinit option is automatically set to no.

The infile keyword allows a file of rigid body attributes to be read in from a file, rather than having LAMMPS compute them. There are 5 such attributes: the total mass of the rigid body, its center-of-mass position, its 6 moments of inertia,
its center-of-mass velocity, and the 3 image flags of the center-of-mass position. For rigid bodies consisting of point particles or non-overlapping finite-size particles, LAMMPS can compute these values accurately. However, for rigid bodies consisting of finite-size particles which overlap each other, LAMMPS will ignore the overlaps when computing these 4 attributes. The amount of error this induces depends on the amount of overlap. To avoid this issue, the values can be pre-computed (e.g. using Monte Carlo integration).

The format of the file is as follows. Note that the file does not have to list attributes for every rigid body integrated by fix rigid. Only bodies which the file specifies will have their computed attributes overridden. The file can contain initial blank lines or comment lines starting with “#” which are ignored. The first non-blank, non-comment line should list \( N \) = the number of lines to follow. The \( N \) successive lines contain the following information:

| ID1 masstotal xcm ycm zcm ixx iyy izz ixy ixz iyz vxcm vycm vzcm lx ly lz ixcm iycm izcm |
| ID2 masstotal xcm ycm zcm ixx iyy izz ixy ixz iyz vxcm vycm vzcm lx ly lz ixcm iycm izcm |
| ... |
| IDN masstotal xcm ycm zcm ixx iyy izz ixy ixz iyz vxcm vycm vzcm lx ly lz ixcm iycm izcm |

The rigid body IDs are all positive integers. For the single bodystyle, only an ID of 1 can be used. For the group bodystyle, IDs from 1 to \( N_g \) can be used where \( N_g \) is the number of specified groups. For the molecule bodystyle, use the molecule ID for the atoms in a specific rigid body as the rigid body ID.

The masstotal and center-of-mass coordinates \((xcm, ycm, zcm)\) are self-explanatory. The center-of-mass should be consistent with what is calculated for the position of the rigid body with all its atoms unwrapped by their respective image flags. If this produces a center-of-mass that is outside the simulation box, LAMMPS wraps it back into the box.

The 6 moments of inertia \((ixx, iyy, izz, ixy, ixz, iyz)\) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally.

The \((vxcm, vycm, vzcm)\) values are the velocity of the center of mass. The \((lx, ly, lz)\) values are the angular momentum of the body. The \((vxcm, vycm, vzcm)\) and \((lx, ly, lz)\) values can simply be set to 0 if you wish the body to have no initial motion.

The \((ixcm, iycm, izcm)\) values are the image flags of the center of mass of the body. For periodic dimensions, they specify which image of the simulation box the body is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as the rigid bodies cross periodic boundaries during the simulation.

**Note:** If you use the *infile* keyword and write restart files during a simulation, then each time a restart file is written, the fix also write an auxiliary restart file with the name rfle.rigid, where “rfle” is the name of the restart file, e.g. tmp.restart.10000 and tmp.restart.10000.rigid. This auxiliary file is in the same format described above. Thus it can be used in a new input script that restarts the run and re-specifies a rigid fix using an *infile* keyword and the appropriate filename. Note that the auxiliary file will contain one line for every rigid body, even if the original file only listed a subset of the rigid bodies.
18.170.4 Restart, fix_modify, output, run start/stop, minimize info

No information is written to binary restart files. If the infile keyword is used, an auxiliary file is written out with rigid body information each time a restart file is written, as explained above for the infile keyword.

None of the fix_modify options are relevant to this fix.

This fix computes a global array of values which can be accessed by various output commands. The number of rows in the array is equal to the number of rigid bodies. The number of columns is 28. Thus for each rigid body, 28 values are stored: the xyz coords of the center of mass (COM), the xyz components of the COM velocity, the xyz components of the force acting on the COM, the components of the 4-vector quaternion representing the orientation of the rigid body, the xyz components of the angular velocity of the body around its COM, the xyz components of the torque acting on the COM, the 3 principal components of the moment of inertia, the xyz components of the angular momentum of the body around its COM, and the xyz image flags of the COM.

The center of mass (COM) for each body is similar to unwrapped coordinates written to a dump file. It will always be inside (or slightly outside) the simulation box. The image flags have the same meaning as image flags for particle positions (see the “dump” command). This means you can calculate the unwrapped COM by applying the image flags to the COM, the same as when unwrapped coordinates are written to a dump file.

The force and torque values in the array are not affected by the force and torque keywords in the fix rigid command; they reflect values before any changes are made by those keywords.

The ordering of the rigid bodies (by row in the array) is as follows. For the single keyword there is just one rigid body. For the molecule keyword, the bodies are ordered by ascending molecule ID. For the group keyword, the list of group IDs determines the ordering of bodies.

The array values calculated by this fix are “intensive”, meaning they are independent of the number of particles in the simulation.

No parameter of this fix can be used with the start/stop keywords of the run command.

This fix is not invoked during energy minimization.

18.170.5 Restrictions

This fix is part of the USER-SDPD package and also depends on the RIGID package. It is only enabled if LAMMPS was built with both packages. See the Build package doc page for more info.

This fix requires that atoms store density and internal energy as defined by the atom_style sph command.

All particles in the group must be mesoscopic SPH/SDPD particles.

18.170.6 Related commands

fix meso/move, fix rigid, neigh_modify exclude
18.170.7 Default

The option defaults are force * on on on and torque * on on on, meaning all rigid bodies are acted on by center-of-mass force and torque. Also reinit = yes.

18.171 fix rx command

Accelerator Variants: rx/kk

18.171.1 Syntax

```
fix ID group-ID rx file localTemp matrix solver minSteps ...
```

- ID, group-ID are documented in fix command
- rx = style name of this fix command
- file = filename containing the reaction kinetic equations and Arrhenius parameters
- localTemp = none, lucy = no local temperature averaging or local temperature defined through Lucy weighting function
- matrix = sparse, dense format for the stoichiometric matrix
- solver = lammps_rk4, rkf45 = rk4 is an explicit fourth order Runge-Kutta method; rkf45 is an adaptive fourth-order Runge-Kutta-Fehlberg method
- minSteps = # of steps for rk4 solver or minimum # of steps for rkf45 (rk4 or rkf45)
- maxSteps = maximum number of steps for the rkf45 solver (rkf45 only)
- relTol = relative tolerance for the rkf45 solver (rkf45 only)
- absTol = absolute tolerance for the rkf45 solver (rkf45 only)
- diag = Diagnostics frequency for the rkf45 solver (optional, rkf45 only)

18.171.2 Examples

```
fix 1 all rx kinetics.rx none dense lammps_rk4
fix 1 all rx kinetics.rx none sparse lammps_rk4 1
fix 1 all rx kinetics.rx lucy sparse lammps_rk4 10
fix 1 all rx kinetics.rx none dense rkf45 1 100 1e-6 1e-8
fix 1 all rx kinetics.rx none dense rkf45 1 100 1e-6 1e-8 -1
```
18.171.3 Description

Fix rx solves the reaction kinetic ODEs for a given reaction set that is defined within the file associated with this command.

For a general reaction such that

\[ \nu_A A + \nu_B B \rightarrow \nu_C C \]

the reaction rate equation is defined to be of the form

\[ r = k(T)[A]^\nu_A [B]^\nu_B \]

In the current implementation, the exponents are defined to be equal to the stoichiometric coefficients. A given reaction set consisting of n reaction equations will contain a total of m species. A set of m ordinary differential equations (ODEs) that describe the change in concentration of a given species as a function of time are then constructed based on the n reaction rate equations.

The ODE systems are solved over the full DPD timestep \( dt \) using either a fourth order Runge-Kutta rk4 method with a fixed step-size \( h \), specified by the lammps_rk4 keyword, or a fourth order Runge-Kutta-Fehlberg (rkf45) method with an adaptive step-size for \( h \). The number of ODE steps per DPD timestep for the rk4 method is optionally specified immediately after the rk4 keyword. The ODE step-size is set as \( dt/\text{num\_steps} \). Smaller step-sizes tend to yield more accurate results but there is not control on the error. For error control, use the rkf45 ODE solver.

The rkf45 method adjusts the step-size so that the local truncation error is held within the specified absolute and relative tolerances. The initial step-size \( h_0 \) can be specified by the user or estimated internally. It is recommended that the user specify \( h_0 \) since this will generally reduced the number of ODE integration steps required. \( h_0 \) is defined as \( dt/\text{min\_steps} \) if \( \text{min\_steps} \geq 1 \). If \( \text{min\_steps} = 0 \), \( h_0 \) is estimated such that an explicit Euler method would likely produce an acceptable solution. This is generally overly conservative for the fourth-order method and users are advised to specify \( h_0 \) as some fraction of the DPD timestep. For small DPD timesteps, only one step may be necessary depending upon the tolerances. Note that more than \( \text{min\_steps} \) ODE steps may be taken depending upon the ODE stiffness but no more than \( \text{max\_steps} \) will be taken. If \( \text{max\_steps} \) is reached, an error warning is printed and the simulation is stopped.

After each ODE step, the solution error \( e \) is tested and weighted using the absTol and relTol values. The error vector is weighted as \( e / (\text{relTol} \times |u| + \text{absTol}) \) where \( u \) is the solution vector. If the norm of the error is \( \leq 1 \), the solution is accepted, \( h \) is increased by a proportional amount, and the next ODE step is begun. Otherwise, \( h \) is shrunk and the ODE step is repeated.

Run-time diagnostics are available for the rkf45 ODE solver. The frequency (in time-steps) that diagnostics are reported is controlled by the last (optional) 12th argument. A negative frequency means that diagnostics are reported once at the end of each run. A positive frequency means that diagnostics are reported once at the end of each run. A positive value \( N \) means that the diagnostics are reported once per \( N \) time-steps.

The diagnostics report the average # of integrator steps and RHS function evaluations and run-time per ODE as well as the average/RMS/min/max per process. If the reporting frequency is 1, the RMS/min/max per ODE are also reported. The per ODE statistics can be used to adjust the tolerance and min/max step parameters. The statistics per MPI process can be useful to examine any load imbalance caused by the adaptive ODE solver. (Some DPD particles can take longer to solve than others. This can lead to an imbalance across the MPI processes.)

The filename specifies a file that contains the entire set of reaction kinetic equations and corresponding Arrhenius parameters. The format of this file is described below.

There is no restriction on the total number or reaction equations that are specified. The species names are arbitrary string names that are associated with the species concentrations. Each species in a given reaction must be preceded by it’s stoichiometric coefficient. The only delimiters that are recognized between the species are either a + or =...
character. The \( = \) character corresponds to an irreversible reaction. After specifying the reaction, the reaction rate constant is determined through the temperature dependent Arrhenius equation:

\[
k = AT^n e^{-\frac{E_a}{k_BT}}
\]

where \( A \) is the Arrhenius factor in time units or concentration/time units, \( n \) is the unitless exponent of the temperature dependence, and \( E_a \) is the activation energy in energy units. The temperature dependence can be removed by specifying the exponent as zero.

The internal temperature of the coarse-grained particles can be used in constructing the reaction rate constants at every DPD timestep by specifying the keyword \textit{none}. Alternatively, the keyword \textit{lucy} can be specified to compute a local-average particle internal temperature for use in the reaction rate constant expressions. The local-average particle internal temperature is defined as:

\[
\theta_t^{-1} = \frac{\sum_{j=1}^{\omega_{Lucy}(r_{ij})} \theta_j^{-1}}{\sum_{j=1}^{\omega_{Lucy}(r_{ij})}}
\]

where the Lucy function is expressed as:

\[
\omega_{Lucy}(r_{ij}) = \left(1 + \frac{3r_{ij}}{r_c}\right) \left(1 - \frac{r_{ij}}{r_c}\right)^3
\]

The self-particle interaction is included in the above equation.

The stoichiometric coefficients for the reaction mechanism are stored in either a sparse or dense matrix format. The dense matrix should only be used for small reaction mechanisms. The sparse matrix should be used when there are many reactions (e.g., more than 5). This allows the number of reactions and species to grow while keeping the computational cost tractable. The matrix format can be specified as using either the \textit{sparse} or \textit{dense} keywords. If all stoichiometric coefficients for a reaction are small integers (whole numbers \( \leq 3 \)), a fast exponential function is used.

This can save significant computational time so users are encouraged to use integer coefficients where possible.

The format of a tabulated file is as follows (without the parenthesized comments):

\[
# Rxn equations and parameters (one or
→ more comment or blank lines)

1.0 hcn + 1.0 no2 = 1.0 no + 0.5 n2 + 0.5 h2 + 1.0 co 2.49E+01 0.0 1.34 (rxn
→ equation, A, n, Ea)
1.0 hcn + 1.0 no = 1.0 co + 1.0 n2 + 0.5 h2 2.16E+00 0.0 1.52
...
1.0 no + 1.0 co = 0.5 n2 + 1.0 co2 1.66E+06 0.0 0.69
\]

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections.

Following a blank line, the next \( N \) lines list the \( N \) reaction equations. Each species within the reaction equation is specified through its stoichiometric coefficient and a species tag. Reactant species are specified on the left-hand side of the equation and product species are specified on the right-hand side of the equation. After specifying the reactant and product species, the final three arguments of each line represent the Arrhenius parameter \( A \), the temperature exponent \( n \), and the activation energy \( E_a \).

Note that the species tags that are defined in the reaction equations are used by the \textit{fix eos/table/rx} command to define the thermodynamic properties of each species. Furthermore, the number of species molecules (i.e., concentration) can be specified either with the \textit{set} command using the “d_” prefix or by reading directly the concentrations from a data file. For the latter case, the \textit{read_data} command with the fix keyword should be specified, where the fix-ID will be the “fix rx’ID with a <SPECIES>”_suffix, e.g.
fix foo all rx reaction.file ... read_data data.dpd fix foo_SPECIES NULL Species

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

### 18.171.4 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

This command also requires use of the *atom_style dpd* command.

This command can only be used with a constant energy or constant enthalpy DPD simulation.

### 18.171.5 Related commands

*fix eos/table/rx*, *fix shardlow*, *pair dpd/fdt/energy*

### 18.172 fix saed/vtk command

#### 18.172.1 Syntax

```plaintext
fix ID group-ID saed/vtk Nevery Nrepeat Nfreq c_ID attribute args ... keyword args ..
```

- ID, group-ID are documented in *fix* command
- saed/vtk = style name of this fix command
- Nevery = use input values every this many timesteps
- Nrepeat = # of times to use input values for calculating averages
- Nfreq = calculate averages every this many timesteps
- c_ID = saed compute ID
keyword = file or ave or start or file or overwrite:

ave args = one or running or window M
  one = output a new average value every Nfreq steps
  running = output cumulative average of all previous Nfreq steps
  window M = output average of M most recent Nfreq steps
start args = Nstart
  Nstart = start averaging on this timestep
file arg = filename
  filename = name of file to output time averages to
overwrite arg = none = overwrite output file with only latest output

18.172.2 Examples

```
compute 1 all saed 0.0251 Al O Kmax 1.70 Zone 0 0 1 dR_Ewald 0.01 c 0.5 0.5 0.5
compute 2 all saed 0.0251 Ni Kmax 1.70 Zone 0 0 0 c 0.05 0.05 0.05 manual echo
fix 1 all saed/vtk 1 1 1 c_1 file Al203_001.saed
fix 2 all saed/vtk 1 1 1 c_2 file Ni_000.saed
```

18.172.3 Description

Time average computed intensities from `compute saed` and write output to a file in the third generation vtk image data format for visualization directly in parallelized visualization software packages like ParaView and VisIt. Note that if no time averaging is done, this command can be used as a convenient way to simply output diffraction intensities at a single snapshot.

To produce output in the image data vtk format ghost data is added outside the Kmax range assigned in the compute saed. The ghost data is assigned a value of -1 and can be removed setting a minimum isovolume of 0 within the visualization software. SAED images can be created by visualizing a spherical slice of the data that is centered at R_Ewald*{h k l}/norm({h k l}), where R_Ewald=1/lambda.

The group specified within this command is ignored. However, note that specified values may represent calculations performed by saed computes which store their own “group” definitions.

Fix saed/vtk is designed to work only with `compute saed` values, e.g.

```
compute 3 top saed 0.0251 Al O
fix saed/vtk 1 1 1 c_3 file Al203_001.saed
```

The Nevery, Nrepeat, and Nfreq arguments specify on what timesteps the input values will be used in order to contribute to the average. The final averaged quantities are generated on timesteps that are a multiple of Nfreq. The average is over Nrepeat quantities, computed in the preceding portion of the simulation every Nevery timesteps. Nfreq must be a multiple of Nevery and Nevery must be non-zero even if Nrepeat is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. Nrepeat*Nevery can not exceed Nfreq.

For example, if Nevery=2, Nrepeat=6, and Nfreq=100, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If Nrepeat=1 and Nfreq = 100, then no time averaging is done; values are simply generated on timesteps 100,200,etc.

The output for fix ave/time/saed is a file written with the third generation vtk image data formatting. The filename assigned by the `file` keyword is appended with _N.vtk where N is an index (0,1,2... ) to account for multiple diffraction intensity outputs.
By default the header contains the following information (with example data):

```plaintext
# vtk DataFile Version 3.0 c_SAED
Image data set
ASCII
DATASET STRUCTURED_POINTS
DIMENSIONS 337 219 209
ASPECT_RATIO 0.00507953 0.00785161 0.00821458
ORIGIN -0.853361 -0.855826 -0.854316
POINT_DATA 15424827
SCALARS intensity float
LOOKUP_TABLE default
...data
```

In this example, kspace is sampled across a 337 x 219 x 209 point mesh where the mesh spacing is approximately 0.005, 0.007, and 0.008 inv(length) units in the k1, k2, and k3 directions, respectively. The data is shifted by -0.85, -0.85, -0.85 inv(length) units so that the origin will lie at 0, 0, 0. Here, 15,424,827 kspace points are sampled in total.

Additional optional keywords also affect the operation of this fix.

The *ave* keyword determines how the values produced every *Nfreq* steps are averaged with values produced on previous steps that were multiples of *Nfreq*, before they are accessed by another output command or written to a file.

If the *ave* setting is *one*, then the values produced on timesteps that are multiples of *Nfreq* are independent of each other; they are output as-is without further averaging.

If the *ave* setting is *running*, then the values produced on timesteps that are multiples of *Nfreq* are summed and averaged in a cumulative sense before being output. Each output value is thus the average of the value produced on that timestep with all preceding values. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the *unfix* command, or by re-defining the fix by re-specifying it.

If the *ave* setting is *window*, then the values produced on timesteps that are multiples of *Nfreq* are summed and averaged within a moving "window" of time, so that the last M values are used to produce the output. E.g. if *M* = 3 and *Nfreq* = 1000, then the output on step 10000 will be the average of the individual values on steps 8000,9000,10000. Outputs on early steps will average over less than *M* values if they are not available.

The *start* keyword specifies what timestep averaging will begin on. The default is step 0. Often input values can be 0.0 at time 0, so setting *start* to a larger value can avoid including a 0.0 in a running or windowed average.

The *file* keyword allows a filename to be specified. Every *Nfreq* steps, the vector of saed intensity data is written to a new file using the third generation vtk format. The base of each file is assigned by the *file* keyword and this string is appended with _N.vtk where N is an index (0,1,2...) to account for situations with multiple diffraction intensity outputs.

The *overwrite* keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the *ave running* setting.

**18.172.4 Restart, fix_modify, output, run start/stop, minimize info**

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*. 
18.172.5 Restrictions

The attributes for fix_saed_vtk must match the values assigned in the associated compute_saed command.

18.172.6 Related commands

</tr>
<tr>
<td>fix 2 edge setforce NULL 0.0 v_oscillate</td>
</tr>
</tbody>
</table>
18.174.3 Description

Set each component of force on each atom in the group to the specified values $f_x,f_y,f_z$. This erases all previously computed forces on the atom, though additional fixes could add new forces. This command can be used to freeze certain atoms in the simulation by zeroing their force, either for running dynamics or performing an energy minimization. For dynamics, this assumes their initial velocity is also zero.

Any of the $f_x,f_y,f_z$ values can be specified as NULL which means do not alter the force component in that dimension.

Any of the 3 quantities defining the force components can be specified as an equal-style or atom-style variable, namely $f_x, f_y, f_z$. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the force component.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent force field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent force field with optional time-dependence as well.

If the region keyword is used, the atom must also be in the specified geometric region in order to have force added to it.

Style spin suffix sets the components of the magnetic precession vectors instead of the mechanical forces. This also erases all previously computed magnetic precession vectors on the atom, though additional magnetic fixes could add new forces.

This command can be used to freeze the magnetic moment of certain atoms in the simulation by zeroing their precession vector.

All options defined above remain valid, they just apply to the magnetic precession vectors instead of the forces.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

The region keyword is also supported by Kokkos, but a Kokkos-enabled region must be used. See the region region command for more information.

These accelerated styles are part of the r Kokkos package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
18.174.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is setting the forces to the desired values; on all other levels, the force is set to 0.0 for the atoms in the fix group, so that setforce values are not counted multiple times. Default is to to override forces at the outermost level.

This fix computes a global 3-vector of forces, which can be accessed by various output commands. This is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command, but you cannot set forces to any value besides zero when performing a minimization. Use the fix addforce command if you want to apply a non-zero force to atoms during a minimization.

18.174.5 Restrictions

The fix setforce/spin only makes sense when LAMMPS was built with the SPIN package.

fix 1 sub rattle 0.0001 20 10 t 5 6 m 1.0 a 31 mol myMol
```

18.176.3 Description

Apply bond and angle constraints to specified bonds and angles in the simulation by either the SHAKE or RATTLE algorithms. This typically enables a longer timestep.

**SHAKE vs RATTLE:**

The SHAKE algorithm was invented for schemes such as standard Verlet timestepping, where only the coordinates are integrated and the velocities are approximated as finite differences to the trajectories (Ryckaert et al. (1977)). If the velocities are integrated explicitly, as with velocity Verlet which is what LAMMPS uses as an integration method, a second set of constraining forces is required in order to eliminate velocity components along the bonds (Andersen (1983)).

In order to formulate individual constraints for SHAKE and RATTLE, focus on a single molecule whose bonds are constrained. Let Ri and Vi be the position and velocity of atom i at time n, for i = 1, …, N, where N is the number of sites of our reference molecule. The distance vector between sites i and j is given by

\[ r_{ij}^{n+1} = r_{ij}^n - r_i^n \]

The constraints can then be formulated as

\[ r_{ij}^{n+1} \cdot r_{ij}^{n+1} = d_{ij}^2 \quad \text{and} \]
\[ v_{ij}^{n+1} \cdot r_{ij}^{n+1} = 0 \]

The SHAKE algorithm satisfies the first condition, i.e. the sites at time n+1 will have the desired separations Dij immediately after the coordinates are integrated. If we also enforce the second condition, the velocity components along the bonds will vanish. RATTLE satisfies both conditions. As implemented in LAMMPS, fix rattle uses fix shake for satisfying the coordinate constraints. Therefore the settings and optional keywords are the same for both fixes, and all the information below about SHAKE is also relevant for RATTLE.

**SHAKE:**

Each timestep the specified bonds and angles are reset to their equilibrium lengths and angular values via the SHAKE algorithm (Ryckaert et al. (1977)). This is done by applying an additional constraint force so that the new positions preserve the desired atom separations. The equations for the additional force are solved via an iterative method that
typically converges to an accurate solution in a few iterations. The desired tolerance (e.g. 1.0e-4 = 1 part in 10000) and maximum # of iterations are specified as arguments. Setting the N argument will print statistics to the screen and log file about regarding the lengths of bonds and angles that are being constrained. Small delta values mean SHAKE is doing a good job.

In LAMMPS, only small clusters of atoms can be constrained. This is so the constraint calculation for a cluster can be performed by a single processor, to enable good parallel performance. A cluster is defined as a central atom connected to others in the cluster by constrained bonds. LAMMPS allows for the following kinds of clusters to be constrained: one central atom bonded to 1 or 2 or 3 atoms, or one central atom bonded to 2 others and the angle between the 3 atoms also constrained. This means water molecules or CH2 or CH3 groups may be constrained, but not all the C-C backbone bonds of a long polymer chain.

The \( b \) constraint lists bond types that will be constrained. The \( t \) constraint lists atom types. All bonds connected to an atom of the specified type will be constrained. The \( m \) constraint lists atom masses. All bonds connected to atoms of the specified masses will be constrained (within a fudge factor of MASSDELTA specified in fix_shake.cpp). The \( a \) constraint lists angle types. If both bonds in the angle are constrained then the angle will also be constrained if its type is in the list.

For all constraints, a particular bond is only constrained if both atoms in the bond are in the group specified with the SHAKE fix.

The degrees-of-freedom removed by SHAKE bonds and angles are accounted for in temperature and pressure computations. Similarly, the SHAKE contribution to the pressure of the system (virial) is also accounted for.

**Note:** This command works by using the current forces on atoms to calculate an additional constraint force which when added will leave the atoms in positions that satisfy the SHAKE constraints (e.g. bond length) after the next time integration step. If you define fixes (e.g. fix efield) that add additional force to the atoms after fix shake operates, then this fix will not take them into account and the time integration will typically not satisfy the SHAKE constraints. The solution for this is to make sure that fix shake is defined in your input script after any other fixes which add or change forces (to atoms that fix shake operates on).

The **mol** keyword should be used when other commands, such as fix deposit or fix pour, add molecules on-the-fly during a simulation, and you wish to constrain the new molecules via SHAKE. You specify a **template-ID** previously defined using the molecule command, which reads a file that defines the molecule. You must use the same **template-ID** that the command adding molecules uses. The coordinates, atom types, special bond restrictions, and SHAKE info can be specified in the molecule file. See the molecule command for details. The only settings required to be in this file (by this command) are the SHAKE info of atoms in the molecule.

Styles with a **gpu**, **intel**, **kk**, **omp**, or **opt** suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the **Speed packages** doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the **Build package** doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the **-suffix command-line switch** when you invoke LAMMPS, or you can use the **suffix** command in your input script.

See the **Speed packages** doc page for more instructions on how to use the accelerated styles effectively.

**RATTLE:**
The velocity constraints lead to a linear system of equations which can be solved analytically. The implementation of the algorithm in LAMMPS closely follows (Andersen (1983)).

Note: The fix rattle command modifies forces and velocities and thus should be defined after all other integration fixes in your input script. If you define other fixes that modify velocities or forces after fix rattle operates, then fix rattle will not take them into account and the overall time integration will typically not satisfy the RATTLE constraints. You can check whether the constraints work correctly by setting the value of RATTLE_DEBUG in src/fix_rattle.cpp to 1 and recompiling LAMMPS.

18.176.4 Restart, fix_modify, output, run start/stop, minimize info

The fix_modify virial option is supported by this fix to add the contribution due to keeping the constraints to the system’s virial as part of thermodynamic output. The default is virial yes

No information about these fixes is written to binary restart files. None of the fix_modify options are relevant to these fixes. No global or per-atom quantities are stored by these fixes for access by various output commands. No parameter of these fixes can be used with the start/stop keywords of the run command. These fixes are not invoked during energy minimization.

18.176.5 Restrictions

These fixes are part of the RIGID package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

For computational efficiency, there can only be one shake or rattle fix defined in a simulation.

If you use a tolerance that is too large or a max-iteration count that is too small, the constraints will not be enforced very strongly, which can lead to poor energy conservation. You can test for this in your system by running a constant NVE simulation with a particular set of SHAKE parameters and monitoring the energy versus time.

SHAKE or RATTLE should not be used to constrain an angle at 180 degrees (e.g. linear CO2 molecule). This causes numeric difficulties. You can use fix rigid or fix rigid/small instead to make a linear molecule rigid.

18.176.6 Related commands

18.177 fix shardlow command

Accelerator Variants: shardlow/kk

18.177.1 Syntax

<table>
<thead>
<tr>
<th>fix ID group-ID shardlow</th>
</tr>
</thead>
</table>

- ID, group-ID are documented in fix command
- shardlow = style name of this fix command

18.177.2 Examples

```bash
fix 1 all shardlow
```

18.177.3 Description

Specifies that the Shardlow splitting algorithm (SSA) is to be used to integrate the DPD equations of motion. The SSA splits the integration into a stochastic and deterministic integration step. The fix shardlow performs the stochastic integration step and must be used in conjunction with a deterministic integrator (e.g. fix nve or fix nph). The stochastic integration of the dissipative and random forces is performed prior to the deterministic integration of the conservative force. Further details regarding the method are provided in (Lisal) and (Larentzos1).

The fix shardlow must be used with the pair_style dpd/ft or pair_style dpd/ft/energy command to properly initialize the fluctuation-dissipation theorem parameter(s) sigma (and kappa, if necessary).

Note that numerous variants of DPD can be specified by choosing an appropriate combination of the integrator and pair_style dpd/ft command. DPD under isothermal conditions can be specified by using fix shardlow, fix nve and pair_style dpd/ft. DPD under isoenergetic conditions can be specified by using fix shardlow, fix nve and pair_style dpd/ft/energy. DPD under isobaric conditions can be specified by using fix shardlow, fix nph and pair_style dpd/ft. DPD under isoenthalpic conditions can be specified by using fix shardlow, fix nph and pair_style dpd/ft/energy. Examples of each DPD variant are provided in the examples/USER/dpd directory.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
18.177.4 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix is currently limited to orthogonal simulation cell geometries.

This fix must be used with an additional fix that specifies time integration, e.g. fix nve or fix nph.

The Shardlow splitting algorithm requires the sizes of the sub-domain lengths to be larger than twice the cutoff+skin. Generally, the domain decomposition is dependent on the number of processors requested.

```

### 18.178.3 Description

This fix implements several options of steered MD (SMD) as reviewed in (Izrailev), which allows to induce conformational changes in systems and to compute the potential of mean force (PMF) along the assumed reaction coordinate (Park) based on Jarzynski’s equality (Jarzynski). This fix borrows a lot from **fix spring** and **fix setforce**.

You can apply a moving spring force to a group of atoms (**tether** style) or between two groups of atoms (**couple** style). The spring can then be used in either constant velocity (**cvel** mode) or in constant force (**cfor** mode) to induce transitions in your systems. When running in **tether** style, you may need some way to fix some other part of the system (e.g. via **fix spring/self**)

The **tether** style attaches a spring between a point at a distance of R0 away from a fixed point x,y,z and the center of mass of the fix group of atoms. A restoring force of magnitude K (R - R0) Mi / M is applied to each atom in the group where K is the spring constant, Mi is the mass of the atom, and M is the total mass of all atoms in the group. Note that K thus represents the total force on the group of atoms, not a per-atom force.

In **cvel** mode the distance R is incremented or decremented monotonously according to the pulling (or pushing) velocity. In **cfor** mode a constant force is added and the actual distance in direction of the spring is recorded.

The **couple** style links two groups of atoms together. The first group is the fix group; the second is specified by group-ID2. The groups are coupled together by a spring that is at equilibrium when the two groups are displaced by a vector in direction x,y,z with respect to each other and at a distance R0 from that displacement. Note that x,y,z only provides a direction and will be internally normalized. But since it represents the absolute displacement of group-ID2 relative to the fix group, (1,1,0) is a different spring than (-1,-1,0). For each vector component, the displacement can be described with the **auto** parameter. In this case the direction is re-computed in every step, which can be useful for steering a local process where the whole object undergoes some other change. When the relative positions and distance between the two groups are not in equilibrium, the same spring force described above is applied to atoms in each of the two groups.

For both the **tether** and **couple** styles, any of the x,y,z values can be specified as NULL which means do not include that dimension in the distance calculation or force application.

For constant velocity pulling (**cvel** mode), the running integral over the pulling force in direction of the spring is recorded and can then later be used to compute the potential of mean force (PMF) by averaging over multiple independent trajectories along the same pulling path.
18.178.4 Restart, fix_modify, output, run start/stop, minimize info

The fix stores the direction of the spring, current pulling target distance and the running PMF to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify virial option is supported by this fix to add the contribution due to the added forces on atoms to the system’s virial as part of thermodynamic output. The default is virial no.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a vector list of 7 quantities, which can be accessed by various output commands. The quantities in the vector are in this order: the x-, y-, and z-component of the pulling force, the total force in direction of the pull, the equilibrium distance of the spring, the distance between the two reference points, and finally the accumulated PMF (the sum of pulling forces times displacement).

The force is the total force on the group of atoms by the spring. In the case of the couple style, it is the force on the fix group (group-ID) or the negative of the force on the second group (group-ID2). The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.178.5 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.179 fix smd/adjust_dt command

18.179.1 Syntax

```
fix  ID group-ID smd/adjust_dt arg
```

- ID, group-ID are documented in `fix` command
- smd/adjust_dt = style name of this fix command
- arg = \textit{s\_fact}
  
  \textit{s\_fact} = safety factor

18.179.2 Examples

```
fix 1 all smd/adjust_dt 0.1
```

18.179.3 Description

The fix calculates a new stable time increment for use with the SMD time integrators.

The stable time increment is based on multiple conditions. For the SPH pair styles, a CFL criterion (Courant, Friedrichs & Lewy, 1928) is evaluated, which determines the speed of sound cannot propagate further than a typical spacing between particles within a single time step to ensure no information is lost. For the contact pair styles, a linear analysis of the pair potential determines a stable maximum time step.

This fix inquires the minimum stable time increment across all particles contained in the group for which this fix is defined. An additional safety factor \textit{s\_fact} is applied to the time increment.

See this PDF guide to use Smooth Mach Dynamics in LAMMPS.

18.179.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no part of USER-SMD supports restarting nor minimization.

18.179.5 Restrictions

This fix is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.180.1 Syntax

```
fix ID group-ID smd/integrate_tlsph keyword values
```

- ID, group-ID are documented in `fix` command
- smd/integrate_tlsph = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = `limit_velocity`

```
limit_velocity value = max_vel
max_vel = maximum allowed velocity
```

18.180.2 Examples

```
fix 1 all smd/integrate_tlsph
fix 1 all smd/integrate_tlsph limit_velocity 1000
```

18.180.3 Description

The fix performs explicit time integration for particles which interact according with the Total-Lagrangian SPH pair style.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

The `limit_velocity` keyword will control the velocity, scaling the norm of the velocity vector to `max_vel` in case it exceeds this velocity limit.

18.180.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no part of USER-SMD supports restarting nor minimization. This fix has no outputs.

18.180.5 Restrictions

This fix is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.
18.180.6 Related commands

```

- ID, group-ID are documented in `fix` command
- smd/integrate_ulsph = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = adjust_radius or limit_velocity

**adjust_radius values** = adjust_radius_factor min_nn max_nn  
**adjust_radius_factor** = factor which scale the smooth/kernel radius  
**min_nn** = minimum number of neighbors  
**max_nn** = maximum number of neighbors

**limit_velocity values** = max_velocity  
**max_velocity** = maximum allowed velocity.

18.181.2 Examples

```
fix 1 all smd/integrate_ulsph adjust_radius 1.02 25 50
fix 1 all smd/integrate_ulsph limit_velocity 1000
```

18.181.3 Description

The fix performs explicit time integration for particles which interact with the updated Lagrangian SPH pair style.  
See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

The *adjust_radius* keyword activates dynamic adjustment of the per-particle SPH smoothing kernel radius such that the number of neighbors per particles remains within the interval \( \text{min\_nn to max\_nn} \).  
The parameter *adjust_radius_factor* determines the amount of adjustment per timestep.  
Typical values are *adjust_radius_factor* =1.02, *min\_nn* =15, and *max\_nn* =20.

The *limit_velocity* keyword will control the velocity, scaling the norm of the velocity vector to max\_vel in case it exceeds this velocity limit.
18.181.4 Restart, fix_modify, output, run start/stop, minimize info

18.182.3 Description

This fix applies only to rigid surfaces read from .STL files via fix smd/wall_surface. It updates position and velocity for the particles in the group each timestep without regard to forces on the particles. The rigid surfaces can thus be moved along simple trajectories during the simulation.

The *LINEAR style moves particles with the specified constant velocity vector $V = (V_x,V_y,V_z)$. This style also sets the velocity of each particle to $V = (V_x,V_y,V_z)$.

The *WIGGLE style moves particles in an oscillatory fashion. Particles are moved along $(v_x,v_y,v_z)$ with constant velocity until a displacement of max_travel is reached. Then, the velocity vector is reversed. This process is repeated.

The *ROTATE style rotates particles around a rotation axis $R = (R_x,R_y,R_z)$ that goes through a point $P = (P_x,P_y,P_z)$. The period of the rotation is also specified. This style also sets the velocity of each particle to $(\omega \times R_{\perp})$ where $\omega$ is its angular velocity around the rotation axis and $R_{\perp}$ is a perpendicular vector from the rotation axis to the particle.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

18.182.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no part of USER-SMD supports restarting nor minimization. This fix has no outputs.

18.183 fix smd/setvel command

18.183.1 Syntax

```
fix ID group-ID smd/setvel vx vy vz keyword value ...
```

- ID, group-ID are documented in fix command
- smd/setvel = style name of this fix command
- vx, vy, vz = velocity component values
- any of vx, vy, vz can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
- keyword = region
  
  region value = region-ID
  region-ID = ID of region particles must be in to have their velocities set

18.183.2 Examples

```
fix top_velocity top_group smd/setvel 1.0 0.0 0.0
```

18.183.3 Description

Set each component of velocity on each particle in the group to the specified values vx, vy, vz, regardless of the forces acting on the particle. This command can be used to impose velocity boundary conditions.

Any of the vx, vy, vz values can be specified as NULL which means do not alter the velocity component in that dimension.

This fix is indented to be used together with a time integration fix.

Any of the 3 quantities defining the velocity components can be specified as an equal-style or atom-style variable, namely vx, vy, vz. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the force component.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent velocity field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent velocity field with optional time-dependence as well.

If the region keyword is used, the particle must also be in the specified geometric region in order to have its velocity set by this command.
18.183.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no part of USER-SMD supports restarting nor minimization. None of the fix_modify options are relevant to this fix.

This fix computes a global 3-vector of forces, which can be accessed by various output commands. This is the total force on the group of atoms. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

18.183.5 Restrictions

This fix is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.184 fix smd/wall_surface command

18.184.1 Syntax

```
fix ID group-ID smd/wall_surface arg type mol-ID
```

- ID, group-ID are documented in fix command
- smd/wall_surface = style name of this fix command
- arg = file

  `file = file name of a triangular mesh in stl format`
- type = particle type to be given to the new particles created by this fix
- mol-ID = molecule-ID to be given to the new particles created by this fix (must be >= 65535)

18.184.2 Examples

```
fix stl_surf all smd/wall_surface tool.stl 2 65535
```
18.184.3 Description

This fix creates reads a triangulated surface from a file in .STL format. For each triangle, a new particle is created which stores the barycenter of the triangle and the vertex positions. The radius of the new particle is that of the minimum circle which encompasses the triangle vertices.

The triangulated surface can be used as a complex rigid wall via the `smd/tri_surface` pair style. It is possible to move the triangulated surface via the `smd/move_tri_surf` fix style.

Immediately after a .STL file has been read, the simulation needs to be run for 0 timesteps in order to properly register the new particles in the system. See the “funnel_flow” example in the USER-SMD examples directory.

See this PDF guide to use Smooth Mach Dynamics in LAMMPS.

18.184.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no part of USER-SMD supports restarting nor minimization. This fix has no outputs.

18.184.5 Restrictions

This fix is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The molecule ID given to the particles created by this fix have to be equal to or larger than 65535.

Within each .STL file, only a single triangulated object must be present, even though the STL format allows for the possibility of multiple objects in one file.

18.187.3 Description

Apply a spring force to a group of atoms or between two groups of atoms. This is useful for applying an umbrella force to a small molecule or lightly tethering a large group of atoms (e.g. all the solvent or a large molecule) to the center of the simulation box so that it does not wander away over the course of a long simulation. It can also be used to hold the centers of mass of two groups of atoms at a given distance or orientation with respect to each other.

The `tether` style attaches a spring between a fixed point \(x, y, z\) and the center of mass of the fix group of atoms. The equilibrium position of the spring is \(R_0\). At each timestep the distance \(R\) from the center of mass of the group of atoms to the tethering point is computed, taking account of wrap-around in a periodic simulation box. A restoring force of magnitude \(K\) (\(R - R_0\)) \(M_i / M\) is applied to each atom in the group where \(K\) is the spring constant, \(M_i\) is the mass of the atom, and \(M\) is the total mass of all atoms in the group. Note that \(K\) thus represents the spring constant for the total force on the group of atoms, not for a spring applied to each atom.

The `couple` style links two groups of atoms together. The first group is the fix group; the second is specified by group-ID2. The groups are coupled together by a spring that is at equilibrium when the two groups are displaced by a vector \(x, y, z\) with respect to each other and at a distance \(R_0\) from that displacement. Note that \(x, y, z\) is the equilibrium displacement of group-ID2 relative to the fix group. Thus \((1,1,0)\) is a different spring than \((-1,-1,0)\). When the relative positions and distance between the two groups are not in equilibrium, the same spring force described above is applied to atoms in each of the two groups.

For both the `tether` and `couple` styles, any of the \(x, y, z\) values can be specified as NULL which means do not include that dimension in the distance calculation or force application.

The first example above pulls the ligand towards the point \((0,0,0)\). The second example holds the ligand near the surface of a sphere of radius 5 around the point \((0,0,0)\). The third example holds the ligand a distance 3 away from the \(z=2\) plane (on either side).

The fourth example holds 2 bilayers a distance 10 apart in \(z\). For the last two examples, imagine a pore (a slab of atoms with a cylindrical hole cut out) oriented with the pore axis along \(z\), and an ion moving within the pore. The fifth example holds the ion a distance of -20 below the \(z=0\) center plane of the pore (umbrella sampling). The last example holds the ion a distance 5 away from the pore axis (assuming the center-of-mass of the pore in \(x, y\) is the pore axis).

Note: The center of mass of a group of atoms is calculated in “unwrapped” coordinates using atom image flags, which means that the group can straddle a periodic boundary. See the `dump` doc page for a discussion of unwrapped coordinates. It also means that a spring connecting two groups or a group and the tether point can cross a periodic boundary and its length be calculated correctly.
18.187.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the energy stored in the spring to the system’s potential energy as part of thermodynamic output.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the spring energy \( E = 0.5 \times K \times r^2 \).

This fix also computes global 4-vector which can be accessed by various output commands. The first 3 quantities in the vector are xyz components of the total force added to the group of atoms by the spring. In the case of the couple style, it is the force on the fix group (group-ID) or the negative of the force on the second group (group-ID2). The fourth quantity in the vector is the magnitude of the force added by the spring, as a positive value if \( (r-R0) > 0 \) and a negative value if \( (r-R0) < 0 \). This sign convention can be useful when using the spring force to compute a potential of mean force (PMF).

The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

Note: If you want the spring energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

18.187.5 Restrictions

none

18.187.6 Related commands

fix drag, fix spring/self, fix spring/rg, fix smd

18.187.7 Default

18.188 fix spring/chunk command

18.188.1 Syntax

```plaintext
fix ID group-ID spring/chunk K chunkID comID
```

- ID, group-ID are documented in fix command
- spring/chunk = style name of this fix command
- \( K \) = spring constant for each chunk (force/distance units)
• chunkID = ID of compute chunk/atom command
• comID = ID of compute com/chunk command

18.188.2 Examples

```
fix restrain all spring/chunk 100 chunkID comID
```

18.188.3 Description

Apply a spring force to the center-of-mass (COM) of chunks of atoms as defined by the compute chunk/atom command. Chunks can be molecules or spatial bins or other groupings of atoms. This is a way of tethering each chunk to its initial COM coordinates.

The chunkID is the ID of a compute chunk/atom command defined in the input script. It is used to define the chunks. The comID is the ID of a compute com/chunk command defined in the input script. It is used to compute the COMs of each chunk.

At the beginning of the first run or minimize command after this fix is defined, the initial COM of each chunk is calculated and stored as R0M, where M is the chunk number. Thereafter, at every timestep (or minimization iteration), the current COM of each chunk is calculated as RM. A restoring force of magnitude K (RM - R0M) Mi / Mm is applied to each atom in each chunk where K is the specified spring constant, Mi is the mass of the atom, and Mm is the total mass of all atoms in the chunk. Note that K thus represents the spring constant for the total force on each chunk of atoms, not for a spring applied to each atom.

18.188.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the locations of the initial per-chunk center of mass coordinates to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion. Since this fix depends on an instance of compute chunk/atom it will check when reading the restart if the chunk still exists and will define the same number of chunks. The restart data is only applied when the number of chunks matches. Otherwise the center of mass coordinates are recomputed.

The fix_modify energy option is supported by this fix to add the energy stored in all the springs to the system’s potential energy as part of thermodynamic output.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the energy of all the springs, i.e. 0.5 * K * r^2 per-spring.

The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

---

**Note:** If you want the spring energies to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.
18.188.5 Restrictions

none

18.188.6 Related commands

fix spring, fix spring/self, fix spring/rg

18.188.7 Default

none

18.189 fix spring/rg command

18.189.1 Syntax

fix ID group-ID spring/rg K RG0

- ID, group-ID are documented in fix command
- spring/rg = style name of this fix command
- K = harmonic force constant (force/distance units)
- RG0 = target radius of gyration to constrain to (distance units)

if RG0 = NULL, use the current RG as the target value

18.189.2 Examples

fix 1 protein spring/rg 5.0 10.0
fix 2 micelle spring/rg 5.0 NULL

18.189.3 Description

Apply a harmonic restraining force to atoms in the group to affect their central moment about the center of mass (radius of gyration). This fix is useful to encourage a protein or polymer to fold/unfold and also when sampling along the radius of gyration as a reaction coordinate (i.e. for protein folding).

The radius of gyration is defined as RG in the first formula. The energy of the constraint and associated force on each atom is given by the second and third formulas, when the group is at a different RG than the target value RG0.

\[
R_G^2 = \frac{1}{M} \sum_i^N m_i \left( x_i - \frac{1}{M} \sum_j^N m_j x_j \right)^2
\]

\[
E = K (R_G - R_{G0})^2
\]

\[
F_i = 2K \frac{m_i}{M} \left( 1 - \frac{R_{G0}}{R_G} \right) \left( x_i - \frac{1}{M} \sum_j^N m_j x_j \right)
\]
The \((x_i - \text{center-of-mass})\) term is computed taking into account periodic boundary conditions, \(m_i\) is the mass of the atom, and \(M\) is the mass of the entire group. Note that \(K\) is thus a force constant for the aggregate force on the group of atoms, not a per-atom force.

If \(R_{G0}\) is specified as NULL, then the RG of the group is computed at the time the fix is specified, and that value is used as the target.

### 18.189.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the currently used reference RG \((R_{G0})\) to binary restart files. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

None of the `fix_modify` options are relevant to this fix.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the reference radius of gyration \(R_{G0}\) used by the fix. energy change due to this fix. The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

The `fix_modify respa` option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

### 18.189.5 Restrictions

### 18.190 fix spring/self command

#### 18.190.1 Syntax

```plaintext
fix ID group-ID spring/self K dir
```

- ID, group-ID are documented in `fix` command
- `spring/self = style name of this fix command`
- `K = spring constant (force/distance units)`
- `dir = xyz, xy, xz, yz, x, y, or z (optional, default: xyz)`

18.190.  fix spring/self command 1381
18.190.2 Examples

```plaintext
fix tether boundary-atoms spring/self 10.0
fix zrest move spring/self 10.0 z
```

18.190.3 Description

Apply a spring force independently to each atom in the group to tether it to its initial position. The initial position for each atom is its location at the time the fix command was issued. At each timestep, the magnitude of the force on each atom is -Kr, where r is the displacement of the atom from its current position to its initial position. The distance r correctly takes into account any crossings of periodic boundary by the atom since it was in its initial position.

With the (optional) dir flag, one can select in which direction the spring force is applied. By default, the restraint is applied in all directions, but it can be limited to the xy-, xz-, yz-plane and the x-, y-, or z-direction, thus restraining the atoms to a line or a plane, respectively.

18.190.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the original coordinates of tethered atoms to binary restart files, so that the spring effect will be the same in a restarted simulation. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify energy option is supported by this fix to add the energy stored in the per-atom springs to the system’s potential energy as part of thermodynamic output.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various output commands. The scalar is an energy which is the sum of the spring energy for each atom, where the per-atom energy is 0.5 * K * r^2. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

**Note:** If you want the per-atom spring energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

18.191 fix srd command

18.191.1 Syntax

```
fix ID group-ID srd N groupbig-ID Tsrd hgrid seed keyword value ...
```

- ID, group-ID are documented in `fix` command
- `srd` = style name of this fix command
- `N` = reset SRD particle velocities every this many timesteps
- `groupbig-ID` = ID of group of large particles that SRDs interact with
- `Tsrd` = temperature of SRD particles (temperature units)
- `hgrid` = grid spacing for SRD grouping (distance units)
- `seed` = random # seed (positive integer)
- zero or more keyword/value pairs may be appended
- keyword = `lamda` or `collision` or `overlap` or `inside` or `exact` or `radius` or `bounce` or `search` or `cubic` or `shift` or `tstat` or `rescale`

  - `lamda` value = mean free path of SRD particles (distance units)
  - `collision` value = `noslip` or `slip` = collision model
  - `overlap` value = `yes` or `no` = whether big particles may overlap
  - `inside` value = `error` or `warn` or `ignore` = how SRD particles which end up inside a big particle are treated
  - `exact` value = `yes` or `no`
  - `radius` value = `rfactor` = scale collision radius by this factor
  - `bounce` value = `Nbounce` = max # of collisions an SRD particle can undergo in one timestep
  - `search` value = `sgrid` = grid spacing for collision partner searching (distance units)
  - `cubic` values = style tolerance
    - `style` = `error` or `warn`
    - `tolerance` = fractional difference allowed (0 <= tol <= 1)
  - `shift` values = flag `shiftseed`
    - `flag` = `yes` or `no` or `possible` = SRD bin shifting for better statistics
      - `yes` = perform bin shifting each time SRD velocities are rescaled
      - `no` = no shifting
      - `possible` = shift depending on mean free path and bin size
  - `tstat` value = `yes` or `no` = thermostat SRD particles or not
rescale value = yes or no or rotate or collide = rescaling of SRD velocities
yes = rescale during velocity rotation and collisions
no = no rescaling
rotate = rescale during velocity rotation, but not collisions
collide = rescale during collisions, but not velocity rotation

18.191.2 Examples

fix 1 srd srd 10 big 1.0 0.25 482984
fix 1 srd srd 10 big 0.5 0.25 482984 collision slip search 0.5

18.191.3 Description

Treat a group of particles as stochastic rotation dynamics (SRD) particles that serve as a background solvent when interacting with big (colloidal) particles in group big-ID. The SRD formalism is described in (Hecht). The key idea behind using SRD particles as a cheap coarse-grained solvent is that SRD particles do not interact with each other, but only with the solute particles, which in LAMMPS can be spheroids, ellipsoids, or line segments, or triangles, or rigid bodies containing multiple spheroids or ellipsoids or line segments or triangles. The collision and rotation properties of the model imbue the SRD particles with fluid-like properties, including an effective viscosity. Thus simulations with large solute particles can be run more quickly, to measure solute properties like diffusivity and viscosity in a background fluid. The usual LAMMPS fixes for such simulations, such as fix deform, fix viscosity, and fix nvt/sllod, can be used in conjunction with the SRD model.

For more details on how the SRD model is implemented in LAMMPS, this paper describes the implementation and usage of pure SRD fluids. This paper, which is nearly complete, describes the implementation and usage of mixture systems (solute particles in an SRD fluid). See the examples/srd directory for sample input scripts using SRD particles in both settings.

This fix does two things:

1. It advects the SRD particles, performing collisions between SRD and big particles or walls every timestep, imparting force and torque to the big particles. Collisions also change the position and velocity of SRD particles.
2. It resets the velocity distribution of SRD particles via random rotations every N timesteps.

SRD particles have a mass, temperature, characteristic timestep $dt_{SRD}$, and mean free path between collisions ($\lambda$). The fundamental equation relating these 4 quantities is

$$\lambda = dt_{SRD} \sqrt{\frac{kBT_{SRD}}{m}}$$

The mass $m$ of SRD particles is set by the mass command elsewhere in the input script. The SRD timestep $dt_{SRD}$ is N times the step $dt$ defined by the timestep command. Big particles move in the normal way via a time integration fix with a short timestep $dt$. SRD particles advect with a large timestep $dt_{SRD} \geq dt$.

If the lambda keyword is not specified, the SRD temperature $T_{SRD}$ is used in the above formula to compute $\lambda$. If the lambda keyword is specified, then the $T_{srdf}$ setting is ignored and the above equation is used to compute the SRD temperature.

The characteristic length scale for the SRD fluid is set by hgrid which is used to bin SRD particles for purposes of resetting their velocities. Normally hgrid is set to be 1/4 of the big particle diameter or smaller, to adequately resolve fluid properties around the big particles.

$\lambda$ cannot be smaller than 0.6 * hgrid, else an error is generated (unless the shift keyword is used, see below). The velocities of SRD particles are bounded by Vmax, which is set so that an SRD particle will not advect further than
$D_{\text{max}} = 4 \lambda \Delta t_{\text{SRD}}$. This means that roughly speaking, $D_{\text{max}}$ should not be larger than a big particle diameter, else SRDs may pass through big particles without colliding. A warning is generated if this is the case.

Collisions between SRD particles and big particles or walls are modeled as a lightweight SRD point particle hitting a heavy big particle of given diameter or a wall at a point on its surface and bouncing off with a new velocity. The collision changes the momentum of the SRD particle. It imparts a force and torque to the big particle. It imparts a force to a wall. Static or moving SRD walls are setup via the fix wall/srd command. For the remainder of this doc page, a collision of an SRD particle with a wall can be viewed as a collision with a big particle of infinite radius and mass.

The collision keyword sets the style of collisions. The slip style means that the tangential component of the SRD particle momentum is preserved. Thus a force is imparted to a big particle, but no torque. The normal component of the new SRD velocity is sampled from a Gaussian distribution at temperature $T_{\text{SRD}}$.

For the noslip style, both the normal and tangential components of the new SRD velocity are sampled from a Gaussian distribution at temperature $T_{\text{SRD}}$. Additionally, a new tangential direction for the SRD velocity is chosen randomly. This collision style imparts torque to a big particle. Thus a time integrator fix that rotates the big particles appropriately should be used.

The overlap keyword should be set to yes if two (or more) big particles can ever overlap. This depends on the pair potential interaction used for big-big interactions, or could be the case if multiple big particles are held together as rigid bodies via the fix rigid command. If the overlap keyword is no and big particles do in fact overlap, then SRD/big collisions can generate an error if an SRD ends up inside two (or more) big particles at once. How this error is treated is determined by the inside keyword. Running with overlap set to no allows for faster collision checking, so it should only be set to yes if needed.

The inside keyword determines how a collision is treated if the computation determines that the timestep started with the SRD particle already inside a big particle. If the setting is error then this generates an error message and LAMMPS stops. If the setting is warn then this generates a warning message and the code continues. If the setting is ignore then no message is generated. One of the output quantities logged by the fix (see below) tallies the number of such events, so it can be monitored. Note that once an SRD particle is inside a big particle, it may remain there for several steps until it drifts outside the big particle.

The exact keyword determines how accurately collisions are computed. A setting of yes computes the time and position of each collision as SRD and big particles move together. A setting of no estimates the position of each collision based on the end-of-timestep positions of the SRD and big particle. If overlap is set to yes, the setting of the exact keyword is ignored since time-accurate collisions are needed.

The radius keyword scales the effective size of big particles. If big particles will overlap as they undergo dynamics, then this keyword can be used to scale down their effective collision radius by an amount $r_{\text{factor}}$, so that SRD particle will only collide with one big particle at a time. For example, in a Lennard-Jones system at a temperature of 1.0 (in reduced LJ units), the minimum separation between two big particles is as small as about 0.88 sigma. Thus an $r_{\text{factor}}$ value of 0.85 should prevent dual collisions.

The bounce keyword can be used to limit the maximum number of collisions an SRD particle undergoes in a single timestep as it bounces between nearby big particles. Note that if the limit is reached, the SRD can be left inside a big particle. A setting of 0 is the same as no limit.

There are 2 kinds of bins created and maintained when running an SRD simulation. The first are “SRD bins” which are used to bin SRD particles and reset their velocities, as discussed above. The second are “search bins” which are used to identify SRD/big particle collisions.

The search keyword can be used to choose a search bin size for identifying SRD/big particle collisions. The default is to use the hgrid parameter for SRD bins as the search bin size. Choosing a smaller or large value may be more efficient, depending on the problem. But, in a statistical sense, it should not change the simulation results.
The `cubic` keyword can be used to generate an error or warning when the bin size chosen by LAMMPS creates SRD bins that are non-cubic or different than the requested value of `hgrid` by a specified `tolerance`. Note that using non-cubic SRD bins can lead to undetermined behavior when rotating the velocities of SRD particles, hence LAMMPS tries to protect you from this problem.

LAMMPS attempts to set the SRD bin size to exactly `hgrid`. However, there must be an integer number of bins in each dimension of the simulation box. Thus the actual bin size will depend on the size and shape of the overall simulation box. The actual bin size is printed as part of the SRD output when a simulation begins.

If the actual bin size in non-cubic by an amount exceeding the tolerance, an error or warning is printed, depending on the style of the `cubic` keyword. Likewise, if the actual bin size differs from the requested `hgrid` value by an amount exceeding the tolerance, then an error or warning is printed. The `tolerance` is a fractional difference. E.g. a tolerance setting of 0.01 on the shape means that if the ratio of any 2 bin dimensions exceeds (1 +/- tolerance) then an error or warning is generated. Similarly, if the ratio of any bin dimension with `hgrid` exceeds (1 +/- tolerance), then an error or warning is generated.

Note: The fix srd command can be used with simulations the size and/or shape of the simulation box changes. This can be due to non-periodic boundary conditions or the use of fixes such as the fix deform or fix wall/srd commands to impose a shear on an SRD fluid or an interaction with an external wall. If the box size changes then the size of SRD bins must be recalculated every reneighboring. This is not necessary if only the box shape changes. This re-binning is always done so as to fit an integer number of bins in the current box dimension, whether it be a fixed, shrink-wrapped, or periodic boundary, as set by the boundary command. If the box size or shape changes, then the size of the search bins must be recalculated every reneighboring. Note that changing the SRD bin size may alter the properties of the SRD fluid, such as its viscosity.

The `shift` keyword determines whether the coordinates of SRD particles are randomly shifted when binned for purposes of rotating their velocities. When no shifting is performed, SRD particles are binned and the velocity distribution of the set of SRD particles in each bin is adjusted via a rotation operator. This is a statistically valid operation if SRD particles move sufficiently far between successive rotations. This is determined by their mean-free path \( \lambda \). If \( \lambda \) is less than 0.6 of the SRD bin size, then shifting is required. A shift means that all of the SRD particles are shifted by a vector whose coordinates are chosen randomly in the range [-1/2 bin size, 1/2 bin size]. Note that all particles are shifted by the same vector. The specified random number `shiftseed` is used to generate these vectors. This operation sufficiently randomizes which SRD particles are in the same bin, even if `lambda` is small.

If the `shift` flag is set to `no`, then no shifting is performed, but bin data will be communicated if bins overlap processor boundaries. An error will be generated if \( \lambda < 0.6 \) of the SRD bin size. If the `shift` flag is set to `possible`, then shifting is performed only if \( \lambda < 0.6 \) of the SRD bin size. A warning is generated to let you know this is occurring. If the `shift` flag is set to `yes` then shifting is performed regardless of the magnitude of \( \lambda \). Note that the `shiftseed` is not used if the `shift` flag is set to `no`, but must still be specified.

Note that shifting of SRD coordinates requires extra communication, hence it should not normally be enabled unless required.

The `tstat` keyword will thermostat the SRD particles to the specified `Tsrd`. This is done every N timesteps, during the velocity rotation operation, by rescaling the thermal velocity of particles in each SRD bin to the desired temperature. If there is a streaming velocity associated with the system, e.g. due to use of the fix deform command to perform a simulation undergoing shear, then that is also accounted for. The mean velocity of each bin of SRD particles is set to the position-dependent streaming velocity, based on the coordinates of the center of the SRD bin. Note that collisions of SRD particles with big particles or walls has a thermostatic effect on the colliding particles, so it may not be necessary to thermostat the SRD particles on a bin by bin basis in that case. Also note that for streaming simulations, if no thermostating is performed (the default), then it may take a long time for the SRD fluid to come to equilibrium with a velocity profile that matches the simulation box deformation.

The `rescale` keyword enables rescaling of an SRD particle’s velocity if it would travel more than 4 mean-free paths in an SRD timestep. If an SRD particle exceeds this velocity it is possible it will be lost when migrating to other processors or that collisions with big particles will be missed, either of which will generate errors. Thus the safest
mode is to run with rescaling enabled. However rescaling removes kinetic energy from the system (the particle’s velocity is reduced). The latter will not typically be a problem if thermostating is enabled via the tstat keyword or if SRD collisions with big particles or walls effectively thermostat the system. If you wish to turn off rescaling (on is the default), e.g. for a pure SRD system with no thermostating so that the temperature does not decline over time, the rescale keyword can be used. The no value turns rescaling off during collisions and the per-bin velocity rotation operation. The collide and rotate values turn it on for one of the operations and off for the other.

Note: This fix is normally used for simulations with a huge number of SRD particles relative to the number of big particles, e.g. 100 to 1. In this scenario, computations that involve only big particles (neighbor list creation, communication, time integration) can slow down dramatically due to the large number of background SRD particles.

Three other input script commands will largely overcome this effect, speeding up an SRD simulation by a significant amount. These are the atom_modify first, neigh_modify include, and comm_modify group commands. Each takes a group-ID as an argument, which in this case should be the group-ID of the big solute particles.

Additionally, when a pair_style for big/big particle interactions is specified, the pair_coeff command should be used to turn off big/SRD interactions, e.g. by setting their epsilon or cutoff length to 0.0.

The “delete_atoms overlap” command may be useful in setting up an SRD simulation to insure there are no initial overlaps between big and SRD particles.

18.191.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix tabulates several SRD statistics which are stored in a vector of length 12, which can be accessed by various output commands. The vector values calculated by this fix are “intensive”, meaning they do not scale with the size of the simulation. Technically, the first 8 do scale with the size of the simulation, but treating them as intensive means they are not scaled when printed as part of thermodynamic output.

These are the 12 quantities. All are values for the current timestep, except for quantity 5 and the last three, each of which are cumulative quantities since the beginning of the run.

- (1) # of SRD/big collision checks performed
- (2) # of SRDs which had a collision
- (3) # of SRD/big collisions (including multiple bounces)
- (4) # of SRD particles inside a big particle
- (5) # of SRD particles whose velocity was rescaled to be < Vmax
- (6) # of bins for collision searching
- (7) # of bins for SRD velocity rotation
- (8) # of bins in which SRD temperature was computed
- (9) SRD temperature
- (10) # of SRD particles which have undergone max # of bounces
- (11) max # of bounces any SRD particle has had in a single step
- (12) # of reneighborings due to SRD particles moving too far

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
18.191.5 Restrictions

This command can only be used if LAMMPS was built with the SRD package. See the Build package doc page for more info.

18.191.6 Related commands

*fix wall/srd*

18.191.7 Default

The option defaults are: \( \lambda \) is inferred from \( T_{sr} \), collision = noslip, overlap = no, inside = error, exact = yes, radius = 1.0, bounce = 0, search = hgrid, cubic = error 0.01, shift = no, tstat = no, and rescale = yes.

(Hecht) Hecht, Harting, Ihle, Herrmann, Phys Rev E, 72, 011408 (2005).

18.192 fix store/force command

18.192.1 Syntax

```
fix ID group-ID store/force
```

- ID, group-ID are documented in *fix command*
- store/force = style name of this fix command

18.192.2 Examples

```
fix 1 all store/force
```

18.192.3 Description

Store the forces on atoms in the group at the point during each timestep when the fix is invoked, as described below. This is useful for storing forces before constraints or other boundary conditions are computed which modify the forces, so that unmodified forces can be *written to a dump file* or accessed by other *output commands* that use per-atom quantities.

This fix is invoked at the point in the velocity-Verlet timestepping immediately after *pair, bond, angle, dihedral, improper, and long-range* forces have been calculated. It is the point in the timestep when various fixes that compute constraint forces are calculated and potentially modify the force on each atom. Examples of such fixes are *fix shake, fix wall, and fix indent*.

Note: The order in which various fixes are applied which operate at the same point during the timestep, is the same as the order they are specified in the input script. Thus normally, if you want to store per-atom forces due to force field...
interactions, before constraints are applied, you should list this fix first within that set of fixes, i.e. before other fixes that apply constraints. However, if you wish to include certain constraints (e.g. fix shake) in the stored force, then it could be specified after some fixes and before others.

18.192.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix produces a per-atom array which can be accessed by various output commands. The number of columns for each atom is 3, and the columns store the x,y,z forces on each atom. The per-atom values be accessed on any timestep. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

d_name = per-atom floating point vector name, managed by fix property/atom
i_name = per-atom integer vector name, managed by fix property/atom

• zero or more keyword/value pairs may be appended

• keyword = com
  com value = yes or no

18.193.2 Examples

```plaintext
fix 1 all store/state 0 x y z
fix 1 all store/state 0 xu yu zu com yes
fix 2 all store/state 1000 vx vy vz
```

18.193.3 Description

Define a fix that stores attributes for each atom in the group at the time the fix is defined. If \( N \) is 0, then the values are never updated, so this is a way of archiving an atom attribute at a given time for future use in a calculation or output. See the discussion of output commands that take fixes as inputs.

If \( N \) is not zero, then the attributes will be updated every \( N \) steps.

Note: Actually, only atom attributes specified by keywords like \( xu \) or \( vy \) or \( radius \) are initially stored immediately at the point in your input script when the fix is defined. Attributes specified by a compute, fix, or variable are not initially stored until the first run following the fix definition begins. This is because calculating those attributes may require quantities that are not defined in between runs.

The list of possible attributes is the same as that used by the dump custom command, which describes their meaning.
If the `com` keyword is set to `yes` then the `xu`, `yu`, and `zu` inputs store the position of each atom relative to the center-of-mass of the group of atoms, instead of storing the absolute position.

The requested values are stored in a per-atom vector or array as discussed below. Zeroes are stored for atoms not in the specified group.

### 18.193.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the per-atom values it stores to binary restart files, so that the values can be restored when a simulation is restarted. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Warning:** When reading data from a restart, the fix command has to be specified exactly the same way as before. LAMMPS will only check whether a fix is of the same style and has the same fix ID and in case of a match will then try to initialize the fix with the data stored in the binary restart file. If the fix store/state command does not match exactly, data can be corrupted or LAMMPS may crash.

None of the `fix_modify` options are relevant to this fix.

If a single input is specified, this fix produces a per-atom vector. If multiple inputs are specified, a per-atom array is produced where the number of columns for each atom is the number of inputs. These can be accessed by various output commands. The per-atom values be accessed on any timestep.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

### 18.193.5 Restrictions

none

`dump custom`, `compute property/atom`, `fix property/atom`, `variable`

### 18.193.7 Default

The option default is `com = no`.

### 18.194 fix temp/berendsen command

#### 18.194.1 Syntax

```
fix ID group-ID temp/berendsen Tstart Tstop Tdamp
```

- ID, group-ID are documented in `fix` command
- `temp/berendsen` = style name of this fix command
- `Tstart,Tstop` = desired temperature at start/end of run
• Tstart can be a variable (see below)

• Tdamp = temperature damping parameter (time units)

18.194.2 Examples

```
fix 1 all temp/berendsen 300.0 300.0 100.0
```

18.194.3 Description

Reset the temperature of a group of atoms by using a Berendsen thermostat (Berendsen), which rescales their velocities every timestep.

The thermostat is applied to only the translational degrees of freedom for the particles, which is an important consideration for finite-size particles which have rotational degrees of freedom being thermostatted with this fix. The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

The desired temperature at each timestep is a ramped value during the run from Tstart to Tstop. The Tdamp parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (tau or fs or ps - see the units command).

Tstart can be specified as an equal-style variable. In this case, the Tstop setting is ignored. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Note: This thermostat will generate an error if the current temperature is zero at the end of a timestep. It cannot rescale a zero temperature.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

Note: Unlike the fix nvt command which performs Nose/Hoover thermostatting AND time integration, this fix does NOT perform time integration. It only modifies velocities to effect thermostatting. Thus you must use a separate time integration fix, like fix nve to actually update the positions of atoms using the modified velocities. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by fix nvt or fix langevin commands.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostatting.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp
```

See the compute temp command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the thermo_style command) with ID = thermo_temp. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via
the `compute_modify` command or print this temperature during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with `compute commands` that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

18.194.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the cumulative global energy change to binary restart files. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

The `fix_modify temp` option is supported by this fix. You can use it to assign a temperature `compute` you have defined to this fix which will be used in its thermostatting procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The `fix_modify energy` option is supported by this fix to add the energy change implied by a velocity rescaling to the system’s potential energy as part of thermodynamic output.

This fix computes a global scalar which can be accessed by various `output commands`. The scalar is the cumulative energy change due to this fix. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

This fix is not invoked during energy minimization.

18.194.5 Restrictions

This fix can be used with dynamic groups as defined by the `group` command. Likewise it can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

fix ID group-ID temp/csld Tstart Tstop Tdamp seed
\end{verbatim}

- ID, group-ID are documented in fixed command
- temp/csvr or temp/csld = style name of this fix command
- Tstart,Tstop = desired temperature at start/end of run
  - Tstart can be a variable (see below)
- Tdamp = temperature damping parameter (time units)
- seed = random number seed to use for white noise (positive integer)

18.196.2 Examples

\begin{verbatim}
fix 1 all temp/csvr 300.0 300.0 100.0 54324
fix 1 all temp/csld 100.0 300.0 10.0 123321
\end{verbatim}

18.196.3 Description

Adjust the temperature with a canonical sampling thermostat that uses global velocity rescaling with Hamiltonian dynamics (temp/csvr) (Bussi1), or Langevin dynamics (temp/csld) (Bussi2). In the case of temp/csvr the thermostat is similar to the empirical Berendsen thermostat in temp/berendsen, but chooses the actual scaling factor from a suitably chosen (gaussian) distribution rather than having it determined from the time constant directly. In the case of temp/csld the velocities are updated to a linear combination of the current velocities with a gaussian distribution of velocities at the desired temperature. Both thermostats are applied every timestep.

The thermostat is applied to only the translational degrees of freedom for the particles, which is an important consideration for finite-size particles which have rotational degrees of freedom being thermostatted with these fixes. The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

The desired temperature at each timestep is a ramped value during the run from \textit{Tstart} to \textit{Tstop}. The \textit{Tdamp} parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (tau or fs or ps - see the \textit{units} command).
$T_{\text{start}}$ can be specified as an equal-style variable. In this case, the $T_{\text{stop}}$ setting is ignored. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

**Note:** Unlike the `fix nvt` command which performs Nose/Hoover thermostatting AND time integration, these fixes do NOT perform time integration. They only modify velocities to effect thermostatting. Thus you must use a separate time integration fix, like `fix nve` to actually update the positions of atoms using the modified velocities. Likewise, these fixes should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by `fix nvt` or `fix langevin` commands.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostatting.

These fixes compute a temperature each timestep. To do this, the fix creates its own compute of style “temp”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp
```

See the `compute temp` command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp`. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the `compute_modify` command or print this temperature during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` will have no effect on this fix.

Like other fixes that perform thermostatting, these fixes can be used with `compute commands` that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

### 18.196.4 Restart, fix_modify, output, run start/stop, minimize info

These fixes write the cumulative global energy change and the random number generator states to `binary restart files`. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the selected fix continues in an uninterrupted fashion. The random number generator state can only be restored when the number of processors remains unchanged from what is recorded in the restart file.

No information about these fixes are written to `binary restart files`.

The `fix_modify temp` option is supported by these fixes. You can use it to assign a temperature `compute` you have defined to these fixes which will be used in its thermostatting procedure, as described above. For consistency, the group used by these fixes and by the compute should be the same.
These fixes can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

These fixes are not invoked during energy minimization.

These fixes compute a global scalar which can be accessed by various output commands. The scalar is the cumulative energy change due to the fix. The scalar value calculated by this fix is “extensive”.

18.196.5 Restrictions

These fixes are not compatible with fix shake.

The fix can be used with dynamic groups as defined by the group command. Likewise it can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

18.196.7 Default

none

18.197 fix temp/rescale command

18.197.1 Syntax

fix ID group-ID temp/rescale N Tstart Tstop window fraction

- ID, group-ID are documented in fix command
- temp/rescale = style name of this fix command
- N = perform rescaling every N steps
- Tstart, Tstop = desired temperature at start/end of run (temperature units)

Tstart can be a variable (see below)

- window = only rescale if temperature is outside this window (temperature units)
- fraction = rescale to target temperature by this fraction
18.197.2 Examples

fix 3 flow temp/rescale 100 1.0 1.1 0.02 0.5
fix 3 boundary temp/rescale 1 1.0 1.5 0.05 1.0
fix 3 boundary temp/rescale 1 1.0 1.5 0.05 1.0

18.197.3 Description

Reset the temperature of a group of atoms by explicitly rescaling their velocities.

The rescaling is applied to only the translational degrees of freedom for the particles, which is an important consideration if finite-size particles which have rotational degrees of freedom are being thermostatted with this fix. The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

Rescaling is performed every N timesteps. The target temperature is a ramped value between the $T_{start}$ and $T_{stop}$ temperatures at the beginning and end of the run.

Note: This thermostat will generate an error if the current temperature is zero at the end of a timestep it is invoked on. It cannot rescale a zero temperature.

$T_{start}$ can be specified as an equal-style variable. In this case, the $T_{stop}$ setting is ignored. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

Rescaling is only performed if the difference between the current and desired temperatures is greater than the window value. The amount of rescaling that is applied is a fraction (from 0.0 to 1.0) of the difference between the actual and desired temperature. E.g. if fraction = 1.0, the temperature is reset to exactly the desired value.

Note: Unlike the fix nvt command which performs Nose/Hoover thermostatting AND time integration, this fix does NOT perform time integration. It only modifies velocities to effect thermostating. Thus you must use a separate time integration fix, like fix nve to actually update the positions of atoms using the modified velocities. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by fix nvt or fix langevin commands.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostating.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp”, as if one of this command had been issued:

```
compute fix-ID_temp group-ID temp
```

See the compute temp for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the thermo_style command) with ID = thermo_temp. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the compute_modify command or print this temperature during thermodynamic output via the thermo_style custom
command using the appropriate compute-ID. It also means that changing attributes of \texttt{thermo\_temp} will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with \texttt{compute commands} that calculate a temperature after removing a “bias” from the atom velocities. E.g. removing the center-of-mass velocity from a group of atoms or only calculating temperature on the x-component of velocity or only calculating temperature for atoms in a geometric region. This is not done by default, but only if the \texttt{fix\_modify} command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual \texttt{compute commands} to determine which ones include a bias. In this case, the thermostat works in the following manner: the current temperature is calculated taking the bias into account, bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

**18.197.4 Restart, fix\_modify, output, run start/stop, minimize info**

This fix writes the cumulative global energy change to \texttt{binary restart files}. See the \texttt{read\_restart} command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

The \texttt{fix\_modify temp} option is supported by this fix. You can use it to assign a temperature \texttt{compute} you have defined to this fix which will be used in its thermostatting procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The \texttt{fix\_modify energy} option is supported by this fix to add the energy change implied by a velocity rescaling to the system’s potential energy as part of \texttt{thermodynamic output}.

This fix computes a global scalar which can be accessed by various \texttt{output commands}. The scalar is the cumulative energy change due to this fix. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the \texttt{start} and \texttt{stop} keywords of the \texttt{run} command. See the \texttt{run} command for details of how to do this.

This fix is not invoked during \texttt{energy minimization}.

```
18.199.3 Description

Perform uniform-acceptance force-bias Monte Carlo (fbMC) simulations, using the time-stamped force-bias Monte Carlo (tfMC) algorithm described in (Mees) and (Bal).

One successful use case of force-bias Monte Carlo methods is that they can be used to extend the time scale of atomistic simulations, in particular when long time scale relaxation effects must be considered; some interesting examples are given in the review by (Neyts). An example of a typical use case would be the modelling of chemical vapor deposition (CVD) processes on a surface, in which impacts by gas-phase species can be performed using MD, but subsequent relaxation of the surface is too slow to be done using MD only. Using tfMC can allow for a much faster relaxation of the surface, so that higher fluxes can be used, effectively extending the time scale of the simulation. (Such an alternating simulation approach could be set up using a loop.)

The initial version of tfMC algorithm in (Mees) contained an estimation of the effective time scale of such a simulation, but it was later shown that the speed-up one can gain from a tfMC simulation is system- and process-dependent, ranging from none to several orders of magnitude. In general, solid-state processes such as (re)crystallization or growth can be accelerated by up to two or three orders of magnitude, whereas diffusion in the liquid phase is not accelerated at all. The observed pseudodynamics when using the tfMC method is not the actual dynamics one would obtain using MD, but the relative importance of processes can match the actual relative dynamics of the system quite well, provided Delta is chosen with care. Thus, the system’s equilibrium is reached faster than in MD, along a path that is generally roughly similar to a typical MD simulation (but not necessarily so). See (Bal) for details.

Each step, all atoms in the selected group are displaced using the stochastic tfMC algorithm, which is designed to sample the canonical (NVT) ensemble at the temperature Temp. Although tfMC is a Monte Carlo algorithm and thus strictly speaking does not perform time integration, it is similar in the sense that it uses the forces on all atoms in order to update their positions. Therefore, it is implemented as a time integration fix, and no other fixes of this type (such as fix nve) should be used at the same time. Because velocities do not play a role in this kind of Monte Carlo simulations, instantaneous temperatures as calculated by temperature computes or thermodynamic output have no meaning: the only relevant temperature is the sampling temperature Temp. Similarly, performing tfMC simulations does not require setting a timestep and the simulated time as calculated by LAMMPS is meaningless.

The critical parameter determining the success of a tfMC simulation is Delta, the maximal displacement length of the lightest element in the system: the larger it is, the longer the effective time scale of the simulation will be (there is an approximately quadratic dependence). However, Delta must also be chosen sufficiently small in order to comply with detailed balance; in general values between 5 and 10 % of the nearest neighbor distance are found to be a good choice. For a more extensive discussion with specific examples, please refer to (Bal), which also describes how the code calculates element-specific maximal displacements from Delta, based on the fourth root of their mass.

Because of the uncorrelated movements of the atoms, the center-of-mass of the fix group will not necessarily be stationary, just like its orientation. When the com keyword is used, all atom positions will be shifted (after every tfMC iteration) in order to fix the position of the center-of-mass along the included directions, by setting the corresponding flag to 1. The rot keyword does the same for the rotational component of the tfMC displacements after every iteration.

Note: the com and rot keywords should not be used if an external force is acting on the specified fix group, along the included directions. This can be either a true external force (e.g. through fix wall) or forces due to the interaction with atoms not included in the fix group. This is because in such cases, translations or rotations of the fix group could be induced by these external forces, and removing them will lead to a violation of detailed balance.
18.199.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.
None of the fix_modify options are relevant to this fix.
This fix is not invoked during energy minimization.

fix 1 all thermal/conductivity 50 z 20 swap 2
```

18.200.3 Description

Use the Muller-Plathe algorithm described in this paper to exchange kinetic energy between two particles in different regions of the simulation box every N steps. This induces a temperature gradient in the system. As described below this enables the thermal conductivity of a material to be calculated. This algorithm is sometimes called a reverse non-equilibrium MD (reverse NEMD) approach to computing thermal conductivity. This is because the usual NEMD approach is to impose a temperature gradient on the system and measure the response as the resulting heat flux. In the Muller-Plathe method, the heat flux is imposed, and the temperature gradient is the system’s response.

See the compute heat/flux command for details on how to compute thermal conductivity in an alternate way, via the Green-Kubo formalism.

The simulation box is divided into Nbin layers in the edim direction, where the layer 1 is at the low end of that dimension and the layer Nbin is at the high end. Every N steps, Nswap pairs of atoms are chosen in the following manner. Only atoms in the fix group are considered. The hottest Nswap atoms in layer 1 are selected. Similarly, the coldest Nswap atoms in the “middle” layer (see below) are selected. The two sets of Nswap atoms are paired up and their velocities are exchanged. This effectively swaps their kinetic energies, assuming their masses are the same. If the masses are different, an exchange of velocities relative to center of mass motion of the 2 atoms is performed, to conserve kinetic energy. Over time, this induces a temperature gradient in the system which can be measured using commands such as the following, which writes the temperature profile (assuming z = edim) to the file tmp.profile:

```plaintext
compute   ke all ke/atom
variable  temp atom c_ke/1.5
compute   layers all chunk/atom bin/1d z lower 0.05 units reduced
fix       3 all ave/chunk 10 100 1000 layers v_temp file tmp.profile
```

Note that by default, Nswap = 1, though this can be changed by the optional swap keyword. Setting this parameter appropriately, in conjunction with the swap rate N, allows the heat flux to be adjusted across a wide range of values, and the kinetic energy to be exchanged in large chunks or more smoothly.

The “middle” layer for velocity swapping is defined as the Nbin/2 + 1 layer. Thus if Nbin = 20, the two swapping layers are 1 and 11. This should lead to a symmetric temperature profile since the two layers are separated by the same distance in both directions in a periodic sense. This is why Nbin is restricted to being an even number.

As described below, the total kinetic energy transferred by these swaps is computed by the fix and can be output. Dividing this quantity by time and the cross-sectional area of the simulation box yields a heat flux. The ratio of heat flux to the slope of the temperature profile is proportional to the thermal conductivity of the fluid, in appropriate units. See the Muller-Plathe paper for details.

**Note:** If your system is periodic in the direction of the heat flux, then the flux is going in 2 directions. This means the effective heat flux in one direction is reduced by a factor of 2. You will see this in the equations for thermal conductivity (kappa) in the Muller-Plathe paper. LAMMPS is simply tallying kinetic energy which does not account for whether or not your system is periodic; you must use the value appropriately to yield a kappa for your system.

**Note:** After equilibration, if the temperature gradient you observe is not linear, then you are likely swapping energy too frequently and are not in a regime of linear response. In this case you cannot accurately infer a thermal conductivity and should try increasing the Nevery parameter.
18.200.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix computes a global scalar which can be accessed by various output commands. The scalar is the cumulative kinetic energy transferred between the bottom and middle of the simulation box (in the edim direction) is stored as a scalar quantity by this fix. This quantity is zeroed when the fix is defined and accumulates thereafter, once every N steps. The units of the quantity are energy; see the units command for details. The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.200.5 Restrictions

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Swaps conserve both momentum and kinetic energy, even if the masses of the swapped atoms are not equal. Thus you should not need to thermostat the system. If you do use a thermostat, you may want to apply it only to the non-swapped dimensions (other than vdim).

LAMMPS does not check, but you should not use this fix to swap the kinetic energy of atoms that are in constrained molecules, e.g. via fix shake or fix rigid. This is because application of the constraints will alter the amount of transferred momentum. You should, however, be able to use flexible molecules. See the Zhang paper for a discussion and results of this idea.

When running a simulation with large, massive particles or molecules in a background solvent, you may want to only exchange kinetic energy between solvent particles.

18.201.2 Example

\begin{verbatim}
fix 1 all ti/spring 50.0 2000 1000 function 2
\end{verbatim}

18.201.3 Description

This fix allows you to compute the free energy of crystalline solids by performing a nonequilibrium thermodynamic integration between the solid of interest and an Einstein crystal. A detailed explanation of how to use this command and choose its parameters for optimal performance and accuracy is given in the paper by Freitas. The paper also presents a short summary of the theory of nonequilibrium thermodynamic integration.

The thermodynamic integration procedure is performed by rescaling the force on each atom. Given an atomic configuration the force \( F \) on each atom is given by

\[ F = (1 - \lambda) F_{\text{solid}} + \lambda F_{\text{harm}} \]

where \( F_{\text{solid}} \) is the force that acts on an atom due to an interatomic potential (\textit{e.g.} EAM potential), \( F_{\text{harm}} \) is the force due to the Einstein crystal harmonic spring, and \( \lambda \) is the coupling parameter of the thermodynamic integration.

An Einstein crystal is a solid where each atom is attached to its equilibrium position by a harmonic spring with spring constant \( k \). With this fix a spring force is applied independently to each atom in the group defined by the fix to tether it to its initial position. The initial position of each atom is its position at the time the fix command was issued.

The fix acts as follows: during the first \( t_{eq} \) steps after the fix is defined the value of \( \lambda \) is zero. This is the period to equilibrate the system in the \( \lambda = 0 \) state. After this the value of \( \lambda \) changes dynamically during the simulation from 0 to 1 according to the function defined using the keyword \textit{function} (described below), this switching from \( \lambda = 0 \) to \( \lambda = 1 \) is done in \( t_s \) steps. Then comes the second equilibration period of \( t_{eq} \) to equilibrate the system in the \( \lambda = 1 \) state. After that, the switching back to the \( \lambda = 0 \) state is made using \( t_s \) timesteps and following the same switching function. After this period the value of \( \lambda \) is kept equal to zero and the fix has no other effect on the dynamics of the system.

The processes described above is known as nonequilibrium thermodynamic integration and is has been shown (Freitas) to present a much superior efficiency when compared to standard equilibrium methods. The reason why the switching it is made in both directions (potential to Einstein crystal and back) is to eliminate the dissipated heat due to the nonequilibrium process. Further details about nonequilibrium thermodynamic integration and its implementation in LAMMPS is available in Freitas.

The \textit{function} keyword allows the use of two different lambda paths. Option 1 results in a constant rate of change of lambda with time:

\[ \lambda(\tau) = \tau \]

where \( \tau \) is the scaled time variable \( t/t_s \). The option 2 performs the lambda switching at a rate defined by the following switching function

\[ \lambda(\tau) = \tau^5 \left( 70\tau^4 - 315\tau^3 + 540\tau^2 - 420\tau + 126 \right) \]
This function has zero slope as lambda approaches its extreme values (0 and 1), according to de Koning this results in smaller fluctuations on the integral to be computed on the thermodynamic integration. The use of option 2 is recommended since it results in better accuracy and less dissipation without any increase in computational resources cost.

Note: As described in Freitas, it is important to keep the center-of-mass fixed during the thermodynamic integration. A nonzero total velocity will result in divergences during the integration due to the fact that the atoms are ‘attached’ to their equilibrium positions by the Einstein crystal. Check the option zero of fix langevin and velocity. The use of the Nose-Hoover thermostat (fix nvt) is NOT recommended due to its well documented issues with the canonical sampling of harmonic degrees of freedom (notice that the chain option will NOT solve this problem). The Langevin thermostat (fix langevin) correctly thermostats the system and we advise its usage with ti/spring command.

18.201.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the original coordinates of tethered atoms to binary restart files, so that the spring effect will be the same in a restarted simulation. See the read restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix modify energy option is supported by this fix to add the energy stored in the per-atom springs to the system’s potential energy as part of thermodynamic output.

This fix computes a global scalar and a global vector quantities which can be accessed by various output commands. The scalar is an energy which is the sum of the spring energy for each atom, where the per-atom energy is 0.5 * k * r^2. The vector has 2 positions, the first one is the coupling parameter lambda and the second one is the time derivative of lambda. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

Note: If you want the per-atom spring energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix modify energy option for this fix.

18.201.5 Related commands

fix spring, fix adapt

18.201.6 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.
18.201.7 Default

The keyword default is function = 1.

18.202 fix tmd command

18.202.1 Syntax

```
fix ID group-ID tmd rho_final file1 N file2
```

- ID, group-ID are documented in fix command
- tmd = style name of this fix command
- rho_final = desired value of rho at the end of the run (distance units)
- file1 = filename to read target structure from
- N = dump TMD statistics every this many timesteps, 0 = no dump
- file2 = filename to write TMD statistics to (only needed if N > 0)

18.202.2 Examples

```
fix 1 all nve
fix 2 tmdatoms tmd 1.0 target_file 100 tmd_dump_file
```

18.202.3 Description

Perform targeted molecular dynamics (TMD) on a group of atoms. A holonomic constraint is used to force the atoms to move towards (or away from) the target configuration. The parameter “rho” is monotonically decreased (or increased) from its initial value to rho_final at the end of the run.

Rho has distance units and is a measure of the root-mean-squared distance (RMSD) between the current configuration of the atoms in the group and the target coordinates listed in file1. Thus a value of rho_final = 0.0 means move the atoms all the way to the final structure during the course of the run.

The target file1 can be ASCII text or a gzipped text file (detected by a .gz suffix). The format of the target file1 is as follows:

```
0.0 25.0 xlo xhi
0.0 25.0 ylo yhi
0.0 25.0 zlo zhi
125 24.97311 1.69005 23.46956 0 0 -1
126 1.94691 2.79640 1.92799 1 0 0
127 0.15906 3.46099 0.79121 1 0 0
...```

The first 3 lines may or may not be needed, depending on the format of the atoms to follow. If image flags are included with the atoms, the first 3 lo/hi lines must appear in the file. If image flags are not included, the first 3 lines should not appear. The 3 lines contain the simulation box dimensions for the atom coordinates, in the same format as in a LAMMPS data file (see the read_data command).

The remaining lines each contain an atom ID and its target x,y,z coordinates. The atom lines (all or none of them) can optionally be followed by 3 integer values: nx,ny,nz. For periodic dimensions, they specify which image of the box the atom is considered to be in, i.e. a value of N (positive or negative) means add N times the box length to the coordinate to get the true value.

The atom lines can be listed in any order, but every atom in the group must be listed in the file. Atoms not in the fix group may also be listed; they will be ignored.

TMD statistics are written to file2 every N timesteps, unless N is specified as 0, which means no statistics.

The atoms in the fix tmd group should be integrated (via a fix nve, nvt, npt) along with other atoms in the system.

Restarts can be used with a fix tmd command. For example, imagine a 10000 timestep run with a rho_initial = 11 and a rho_final = 1. If a restart file was written after 2000 time steps, then the configuration in the file would have a rho value of 9. A new 8000 time step run could be performed with the same rho_final = 1 to complete the conformational change at the same transition rate. Note that for restarted runs, the name of the TMD statistics file should be changed to prevent it being overwritten.

For more information about TMD, see (Schlitter1) and (Schlitter2).

18.202.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

No global or per-atom quantities are stored by this fix for access by various output commands.

This fix can ramp its rho parameter over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

18.202.5 Restrictions

All TMD fixes must be listed in the input script after all integrator fixes (nve, nvt, npt) are applied. This ensures that atoms are moved before their positions are corrected to comply with the constraint.

Atoms that have a TMD fix applied should not be part of a group to which a SHAKE fix is applied. This is because LAMMPS assumes there are not multiple competing holonomic constraints applied to the same atoms.

To read gzipped target files, you must compile LAMMPS with the -DLAMMPS_GZIP option. See the Build settings doc page for details.

18.204.3 Description

Use a two-temperature model (TTM) to represent heat transfer through and between electronic and atomic subsystems. LAMMPS models the atomic subsystem as usual with a molecular dynamics model and the classical force field specified by the user, but the electronic subsystem is modeled as a continuum, or a background “gas”, on a regular grid. Energy can be transferred spatially within the grid representing the electrons. Energy can also be transferred between the electronic and the atomic subsystems. The algorithm underlying this fix was derived by D. M. Duffy and A. M. Rutherford and is discussed in two J Physics: Condensed Matter papers: (Duffy) and (Rutherford). They used this algorithm in cascade simulations where a primary knock-on atom (PKA) was initialized with a high velocity to simulate a radiation event.

The description in this sub-section applies to both fix ttm and fix ttm/mod. Fix ttm/mod adds options to account for external heat sources (e.g. at a surface) and for specifying parameters that allow the electronic heat capacity to depend strongly on electronic temperature. It is more expensive computationally than fix ttm because it treats the thermal diffusion equation as non-linear. More details on fix ttm/mod are given below.

Heat transfer between the electronic and atomic subsystems is carried out via an inhomogeneous Langevin thermostat. This thermostat differs from the regular Langevin thermostat (fix langevin) in three important ways. First, the Langevin thermostat is applied uniformly to all atoms in the user-specified group for a single target temperature, whereas the TTM fix applies Langevin thermostatting locally to atoms within the volumes represented by the user-specified grid points with a target temperature specific to that grid point. Second, the Langevin thermostat couples the temperature of the atoms to an infinite heat reservoir, whereas the heat reservoir for fix TTM is finite and represents the local electrons. Third, the TTM fix allows users to specify not just one friction coefficient, but rather two independent friction coefficients: one for the electron-ion interactions (gamma_p), and one for electron stopping (gamma_s).

When the friction coefficient due to electron stopping, gamma_s, is non-zero, electron stopping effects are included for atoms moving faster than the electron stopping critical velocity, v_0. For further details about this algorithm, see (Duffy) and (Rutherford).

Energy transport within the electronic subsystem is solved according to the heat diffusion equation with added source terms for heat transfer between the subsystems:

\[ C_e \rho_e \frac{\partial T_e}{\partial t} = \nabla (\kappa_e \nabla T_e) - g_p(T_e - T_a) + g_s T_a' \]

where C_e is the specific heat, rho_e is the density, kappa_e is the thermal conductivity, T is temperature, the “e” and “a” subscripts represent electronic and atomic subsystems respectively, g_p is the coupling constant for the electron-ion interaction, and g_s is the electron stopping coupling parameter. C_e, rho_e, and kappa_e are specified as parameters to the fix. The other quantities are derived. The form of the heat diffusion equation used here is almost the same as that in equation 6 of (Duffy), with the exception that the electronic density is explicitly represented, rather than being part of the specific heat parameter.
Currently, fix ttm assumes that none of the user-supplied parameters will vary with temperature. Note that (Duffy) used a tanh() functional form for the temperature dependence of the electronic specific heat, but ignored temperature dependencies of any of the other parameters. See more discussion below for fix ttm/mod.

These fixes require use of periodic boundary conditions and a 3D simulation. Periodic boundary conditions are also used in the heat equation solve for the electronic subsystem. This varies from the approach of (Rutherford) where the atomic subsystem was embedded within a larger continuum representation of the electronic subsystem.

The initial electronic temperature input file, \( T_{\text{in file}} \), is a text file LAMMPS reads in with no header and with four numeric columns \((i_x,i_y,i_z,\text{Temp})\) and with a number of rows equal to the number of user-specified grid points \((N_x \times N_y \times N_z)\). The \(i_x,i_y,i_z\) are node indices from 0 to \(nxnodes-1\), etc. For example, the initial electronic temperatures on a 1 by 2 by 3 grid could be specified in a \( T_{\text{in file}} \) as follows:

```
0 0 0 1.0
0 0 1 1.0
0 0 2 1.0
0 1 0 2.0
0 1 1 2.0
0 1 2 2.0
```

where the electronic temperatures along the \(y=0\) plane have been set to 1.0, and the electronic temperatures along the \(y=1\) plane have been set to 2.0. The order of lines in this file is no important. If all the nodal values are not specified, LAMMPS will generate an error.

The temperature output file, \( T_{\text{out file}} \), is created and written by this fix. Temperatures for both the electronic and atomic subsystems at every node and every N timesteps are output. If N is specified as zero, no output is generated, and no output filename is needed. The format of the output is as follows. One long line is written every output timestep. The timestep itself is given in the first column. The next \( N_x \times N_y \times N_z \) columns contain the temperatures for the atomic subsystem, and the final \( N_x \times N_y \times N_z \) columns contain the temperatures for the electronic subsystem. The ordering of the \( N_x \times N_y \times N_z \) columns is with the \(z\) index varying fastest, \(y\) the next fastest, and \(x\) the slowest.

These fixes do not change the coordinates of their atoms; they only scales their velocities. Thus a time integration fix (e.g. fix nve) should still be used to time integrate the affected atoms. The fixes should not normally be used on atoms that have their temperature controlled by another fix - e.g. fix nvt or fix langevin.

**Note:** The current implementations of these fixes create a copy of the electron grid that overlays the entire simulation domain, for each processor. Values on the grid are summed across all processors. Thus you should insure that this grid is not too large, else your simulation could incur high memory and communication costs.

**Additional details for fix ttm/mod**

Fix ttm/mod uses the heat diffusion equation with possible external heat sources (e.g. laser heating in ablation simulations):

\[
C_e \rho_e \frac{\partial T_e}{\partial t} = \nabla(\kappa_e \nabla T_e) - g_p(T_e - T_a) + g_s T_a' + \theta(x - x_{\text{surface}})I_0 \exp(-x/l_{\text{skin}})
\]

where \(\theta\) is the Heaviside step function, \(I_0\) is the (absorbed) laser pulse intensity for ablation simulations, \(l_{\text{skin}}\) is the depth of skin-layer, and all other designations have the same meaning as in the former equation. The duration of the pulse is set by the parameter \(\tau\) in the init file.

Fix ttm/mod also allows users to specify the dependencies of \(C_e\) and \(\kappa_e\) on the electronic temperature. The specific heat is expressed as

\[
C_e = C_0 + (a_0 + a_1 X + a_2 X^2 + a_3 X^3 + a_4 X^4) \exp(-(AX)^2)
\]
where $X = T_e/1000$, and the thermal conductivity is defined as $\kappa_e = D_e \rho_e C_e$, where $D_e$ is the thermal diffusion coefficient.

Electronic pressure effects are included in the TTM model to account for the blast force acting on ions because of electronic pressure gradient (see (Chen), (Norman)). The total force acting on an ion is:

$$\vec{F}_i = -\frac{\partial U}{\partial \vec{r}_i} + \vec{F}_{\text{langevin}} - \nabla P_e/n_{ion}$$

where $F_{\text{langevin}}$ is a force from Langevin thermostat simulating electron-phonon coupling, and $\nabla P_e/n_{ion}$ is the electron blast force.

The electronic pressure is taken to be

$$P_e = B \rho_e C_e T_e$$

The current fix ttm/mod implementation allows TTM simulations with a vacuum. The vacuum region is defined as the grid cells with zero electronic temperature. The numerical scheme does not allow energy exchange with such cells. Since the material can expand to previously unoccupied region in some simulations, the vacuum border can be allowed to move. It is controlled by the surface_movement parameter in the init_file. If it is set to 1, then “vacuum” cells can be changed to “electron-filled” cells with the temperature $T_{e\_min}$ if atoms move into them (currently only implemented for the case of 1-dimensional motion of flat surface normal to the X axis). The initial borders of vacuum can be set in the init_file via lsurface and rsurface parameters. In this case, electronic pressure gradient is calculated as

$$\nabla P_e = \left[ \frac{C_e T_e(x) \lambda}{(x + \lambda)^2} + \frac{x}{x + \lambda} \frac{(C_e T_e)_{x+\Delta x} - (C_e T_e)_x}{\Delta x} \right]$$

where lambda is the electron mean free path (see (Norman), (Pisarev)).

The fix ttm/mod parameter file init_file has the following syntax/Every line with the odd number is considered as a comment and ignored. The lines with the even numbers are treated as follows:

- $a_0$, energy/(temperature\_electron) units
- $a_1$, energy/(temperature^2\_electron) units
- $a_2$, energy/(temperature^3\_electron) units
- $a_3$, energy/(temperature^4\_electron) units
- $a_4$, energy/(temperature^5\_electron) units
- $C_0$, energy/(temperature\_electron) units
- $A$, 1/temperature units
- $\rho_e$, electrons/volume units
- $D_e$, length^2/time units
- $\gamma_p$, mass/time units
- $\gamma_s$, mass/time units
- $v_0$, length/time units
- $I_0$, energy/(time\_length^2) units
- $lsurface$, electron grid units (positive integer)
- $rsurface$, electron grid units (positive integer)
- $l\_skin$, length units
- $tau$, time units
- $B$, dimensionless
- $lambda$, length units
- $n_{ion}$, ions/volume units
- surface_movement: 0 to disable tracking of surface motion, 1 to enable
- $T_{e\_min}$, temperature units

---

1412 Chapter 18. Fixes
18.204.4 Restart, fix_modify, output, run start/stop, minimize info

These fixes write the state of the electronic subsystem and the energy exchange between the subsystems to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

Because the state of the random number generator is not saved in the restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

None of the fix_modify options are relevant to these fixes.

Both fixes compute 2 output quantities stored in a vector of length 2, which can be accessed by various output commands. The first quantity is the total energy of the electronic subsystem. The second quantity is the energy transferred from the electronic to the atomic subsystem on that timestep. Note that the velocity verlet integrator applies the fix ttm forces to the atomic subsystem as two half-step velocity updates: one on the current timestep and one on the subsequent timestep. Consequently, the change in the atomic subsystem energy is lagged by half a timestep relative to the change in the electronic subsystem energy. As a result of this, users may notice slight fluctuations in the sum of the atomic and electronic subsystem energies reported at the end of the timestep.

The vector values calculated are “extensive”.

No parameter of the fixes can be used with the start/stop keywords of the run command. The fixes are not invoked during energy minimization.

18.204.5 Restrictions

Fix ttm is part of the MISC package. It is only enabled if LAMMPS was built with that package. Fix ttm/mod is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These fixes can only be used for 3d simulations and orthogonal simulation boxes. You must also use periodic boundary conditions.

18.205 fix tune/kspace command

18.205.1 Syntax

```plaintext
fix ID group-ID tune/kspace N
```

- ID, group-ID are documented in `fix` command
- tune/kspace = style name of this fix command
- N = invoke this fix every N steps

18.205.2 Examples

```plaintext
fix 2 all tune/kspace 100
```

18.205.3 Description

This fix tests each kspace style (Ewald, PPPM, and MSM), and automatically selects the fastest style to use for the remainder of the run. If the fastest style is Ewald or PPPM, the fix also adjusts the Coulombic cutoff towards optimal speed. Future versions of this fix will automatically select other kspace parameters to use for maximum simulation speed. The kspace parameters may include the style, cutoff, grid points in each direction, order, Ewald parameter, MSM parallelization cut-point, MPI tasks to use, etc.

The rationale for this fix is to provide the user with as-fast-as-possible simulations that include long-range electrostatics (kspace) while meeting the user-prescribed accuracy requirement. A simple heuristic could never capture the optimal combination of parameters for every possible run-time scenario. But by performing short tests of various kspace parameter sets, this fix allows parameters to be tailored specifically to the user’s machine, MPI ranks, use of threading or accelerators, the simulated system, and the simulation details. In addition, it is possible that parameters could be evolved with the simulation on-the-fly, which is useful for systems that are dynamically evolving (e.g. changes in box size/shape or number of particles).

When this fix is invoked, LAMMPS will perform short timed tests of various parameter sets to determine the optimal parameters. Tests are performed on-the-fly, with a new test initialized every N steps. N should be chosen large enough so that adequate CPU time lapses between tests, thereby providing statistically significant timings. But N should not be chosen to be so large that an unfortunate parameter set test takes an inordinate amount of wall time to complete. An N of 100 for most problems seems reasonable. Once an optimal parameter set is found, that set is used for the remainder of the run.

This fix uses heuristics to guide it’s selection of parameter sets to test, but the actual timed results will be used to decide which set to use in the simulation.

It is not necessary to discard trajectories produced using sub-optimal parameter sets, or a mix of various parameter sets, since the user-prescribed accuracy will have been maintained throughout. However, some users may prefer to use this fix only to discover the optimal parameter set for a given setup that can then be used on subsequent production runs.

This fix starts with kspace parameters that are set by the `kspace_style` and `kspace_modify` commands. The prescribed accuracy will be maintained by this fix throughout the simulation.

None of the `fix_modify` options are relevant to this fix.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.
18.205.4 Restrictions

This fix is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

Do not set “neigh_modify once yes” or else this fix will never be called. Reneighboring is required.

This fix is not compatible with a hybrid pair style, long-range dispersion, TIP4P water support, or long-range point dipole support.

18.205.5 Related commands

18.205.6 Default

18.206 fix vector command

18.206.1 Syntax

```
fix ID group-ID vector Nevery value1 value2 ...
```

- ID, group-ID are documented in `fix` command
- vector = style name of this fix command
- Nevery = use input values every this many timesteps
- one or more input values can be listed
- value = c_ID, c_ID[N], f_ID, f_ID[N], v_name

```
c_ID = global scalar calculated by a compute with ID
c_ID[I] = Ith component of global vector calculated by a compute with ID
f_ID = global scalar calculated by a fix with ID
f_ID[I] = Ith component of global vector calculated by a fix with ID
v_name = value calculated by an equal-style variable with name
v_name[I] = Ith component of vector-style variable with name
```

18.206.2 Examples

```
fix 1 all vector 100 c_myTemp
fix 1 all vector 5 c_myTemp v_integral
```
18.206.3 Description

Use one or more global values as inputs every few timesteps, and simply store them. For a single specified value, the values are stored as a global vector of growing length. For multiple specified values, they are stored as rows in a global array, whose number of rows is growing. The resulting vector or array can be used by other output commands.

One way to to use this command is to accumulate a vector that is time-integrated using the variable trap() function. For example the velocity auto-correlation function (VACF) can be time-integrated, to yield a diffusion coefficient, as follows:

| compute     | 2 all vacf        |
| fix         | 5 all vector 1 c_2[4] |
| variable    | diff equal dt*trap(f_5) |
| thermo_style| custom step v_diff |

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a compute or fix or the evaluation of an equal-style or vector-style variable. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity. And the global quantity must be a scalar, not a vector or array.

Computes that produce global quantities are those which do not have the word atom in their style name. Only a few fixes produce global quantities. See the doc pages for individual fixes for info on which ones produce such values. Variables of style equal or vector are the only ones that can be used with this fix. Variables of style atom cannot be used, since they produce per-atom values.

The Nevery argument specifies on what timesteps the input values will be used in order to be stored. Only timesteps that are a multiple of Nevery, including timestep 0, will contribute values.

Note that if you perform multiple runs, using the “pre no” option of the run command to avoid initialization on subsequent runs, then you need to use the stop keyword with the first run command with a timestep value that encompasses all the runs. This is so that the vector or array stored by this fix can be allocated to a sufficient size.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the Ith element of the global vector calculated by the compute is used.

Note that there is a compute reduce command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by fix vector. Or it can be a compute defined not in your input script, but by thermodynamic output or other fixes such as fix nvt or fix temp/rescale. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and add them to LAMMPS.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used.

Note that some fixes only produce their values on certain timesteps, which must be compatible with Nevery, else an error will result. Users can also write code for their own fix styles and add them to LAMMPS.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. An equal-style or vector-style variable can be referenced; the latter requires a bracketed term to specify the Ith element of the vector calculated by the variable. See the variable command for details. Note that variables of style equal and vector define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to be stored by fix vector.
18.206.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix produces a global vector or global array which can be accessed by various output commands. The values can only be accessed on timesteps that are multiples of Nevery.

A vector is produced if only a single input value is specified. An array is produced if multiple input values are specified. The length of the vector or the number of rows in the array grows by 1 every Nevery timesteps.

If the fix produces a vector, then the entire vector will be either “intensive” or “extensive”, depending on whether the values stored in the vector are “intensive” or “extensive”. If the fix produces an array, then all elements in the array must be the same, either “intensive” or “extensive”. If a compute or fix provides the value stored, then the compute or fix determines whether the value is intensive or extensive; see the doc page for that compute or fix for further info.

Values produced by a variable are treated as intensive.

This fix can allocate storage for stored values accumulated over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this. If using the run pre no command option, this is required to allow the fix to allocate sufficient storage for stored values.

This fix is not invoked during energy minimization.

```fortran
fix 1 all viscosity 100 x z 20
fix 1 all viscosity 50 x z 20 swap 2 vtarget 1.5
```

18.207.3 Description

Use the Muller-Plathe algorithm described in this paper to exchange momenta between two particles in different regions of the simulation box every N steps. This induces a shear velocity profile in the system. As described below this enables a viscosity of the fluid to be calculated. This algorithm is sometimes called a reverse non-equilibrium MD (reverse NEMD) approach to computing viscosity. This is because the usual NEMD approach is to impose a shear velocity profile on the system and measure the response via an off-diagonal component of the stress tensor, which is proportional to the momentum flux. In the Muller-Plathe method, the momentum flux is imposed, and the shear velocity profile is the system’s response.

The simulation box is divided into Nbin layers in the pdim direction, where the layer 1 is at the low end of that dimension and the layer Nbin is at the high end. Every N steps, Nswap pairs of atoms are chosen in the following manner. Only atoms in the fix group are considered. Nswap atoms in layer 1 with positive velocity components in the vdim direction closest to the target value \( V \) are selected. Similarly, Nswap atoms in the “middle” layer (see below) with negative velocity components in the vdim direction closest to the negative of the target value \( V \) are selected. The two sets of Nswap atoms are paired up and their vdim momenta components are swapped within each pair. This resets their velocities, typically in opposite directions. Over time, this induces a shear velocity profile in the system which can be measured using commands such as the following, which writes the profile to the file tmp.profile:

```fortran
compute layers all chunk/atom bin/1d z lower 0.05 units reduced
fix f1 all ave/chunk 100 10 1000 layers vx file tmp.profile
```

Note that by default, Nswap = 1 and vtarget = INF, though this can be changed by the optional swap and vtarget keywords. When vtarget = INF, one or more atoms with the most positive and negative velocity components are selected. Setting these parameters appropriately, in conjunction with the swap rate N, allows the momentum flux rate to be adjusted across a wide range of values, and the momenta to be exchanged in large chunks or more smoothly.

The “middle” layer for momenta swapping is defined as the Nbin/2 + 1 layer. Thus if Nbin = 20, the two swapping layers are 1 and 11. This should lead to a symmetric velocity profile since the two layers are separated by the same distance in both directions in a periodic sense. This is why Nbin is restricted to being an even number.

As described below, the total momentum transferred by these velocity swaps is computed by the fix and can be output. Dividing this quantity by time and the cross-sectional area of the simulation box yields a momentum flux. The ratio of momentum flux to the slope of the shear velocity profile is proportional to the viscosity of the fluid, in appropriate units. See the Muller-Plathe paper for details.

Note: If your system is periodic in the direction of the momentum flux, then the flux is going in 2 directions. This means the effective momentum flux in one direction is reduced by a factor of 2. You will see this in the equations for viscosity in the Muller-Plathe paper. LAMMPS is simply tallying momentum which does not account for whether or not your system is periodic; you must use the value appropriately to yield a viscosity for your system.

Note: After equilibration, if the velocity profile you observe is not linear, then you are likely swapping momentum
too frequently and are not in a regime of linear response. In this case you cannot accurately infer a viscosity and should try increasing the Nevery parameter.

An alternative method for calculating a viscosity is to run a NEMD simulation, as described on the Howto nemd doc page. NEMD simulations deform the simulation box via the fix deform command. Thus they cannot be run on a charged system using a PPPM solver since PPPM does not currently support non-orthogonal boxes. Using fix viscosity keeps the box orthogonal; thus it does not suffer from this limitation.

18.207.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix computes a global scalar which can be accessed by various output commands. The scalar is the cumulative momentum transferred between the bottom and middle of the simulation box (in the pdim direction) and stored as a scalar quantity by this fix. This quantity is zeroed when the fix is defined and accumulates thereafter, once every N steps. The units of the quantity are momentum = mass*velocity. The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.207.5 Restrictions

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Swaps conserve both momentum and kinetic energy, even if the masses of the swapped atoms are not equal. Thus you should not need to thermostat the system. If you do use a thermostat, you may want to apply it only to the non-swapped dimensions (other than vdim).

LAMMPS does not check, but you should not use this fix to swap velocities of atoms that are in constrained molecules, e.g. via fix shake or fix rigid. This is because application of the constraints will alter the amount of transferred momentum. You should, however, be able to use flexible molecules. See the Maginn paper for an example of using this algorithm in a computation of alcohol molecule properties.

When running a simulation with large, massive particles or molecules in a background solvent, you may want to only exchange momenta between solvent particles.

18.208 fix viscous command

18.208.1 Syntax

```
fix ID group-ID viscous gamma keyword values ...
```

- ID, group-ID are documented in `fix` command
- viscous = style name of this fix command
- gamma = damping coefficient (force/velocity units)
- zero or more keyword/value pairs may be appended

```
keyword = scale
         scale values = type ratio
         type = atom type (1-N)
         ratio = factor to scale the damping coefficient by
```

18.208.2 Examples

```
fix 1 flow viscous 0.1
fix 1 damp viscous 0.5 scale 3 2.5
```

18.208.3 Description

Add a viscous damping force to atoms in the group that is proportional to the velocity of the atom. The added force can be thought of as a frictional interaction with implicit solvent, i.e. the no-slip Stokes drag on a spherical particle. In granular simulations this can be useful for draining the kinetic energy from the system in a controlled fashion. If used without additional thermostatting (to add kinetic energy to the system), it has the effect of slowly (or rapidly) freezing the system; hence it can also be used as a simple energy minimization technique.

The damping force $F_i$ is given by $F_i = -\gamma v_i$. The larger the coefficient, the faster the kinetic energy is reduced. If the optional keyword `scale` is used, $\gamma$ can be scaled up or down by the specified factor for atoms of that type. It can be used multiple times to adjust $\gamma$ for several atom types.

**Note:** You should specify gamma in force/velocity units. This is not the same as mass/time units, at least for some of the LAMMPS `units` options like “real” or “metal” that are not self-consistent.

In a Brownian dynamics context, $\gamma = \frac{k_B T}{D}$, where $k_B$ = Boltzmann’s constant, $T$ = temperature, and $D$ = particle diffusion coefficient. $D$ can be written as $\frac{k_B T}{3\pi\eta d}$, where $\eta$ = dynamic viscosity of the frictional fluid and $d$ = diameter of particle. This means $\gamma = \frac{3\pi\eta d}{k_B T}$, and thus is proportional to the viscosity of the fluid and the particle diameter.

In the current implementation, rather than have the user specify a viscosity, $\gamma$ is specified directly in force/velocity units. If needed, $\gamma$ can be adjusted for atoms of different sizes (i.e. $\sigma$) by using the `scale` keyword.

Note that Brownian dynamics models also typically include a randomized force term to thermostat the system at a chosen temperature. The `fix langevin` command does this. It has the same viscous damping term as fix viscous and adds a random force to each atom. The random force term is proportional to the square root of the chosen thermostatting temperature. Thus if you use `fix langevin` with a target $T = 0$, its random force term is zero, and you are essentially performing the same operation as fix viscous. Also note that the gamma of fix viscous is related to the damping parameter of `fix langevin`, however the former is specified in units of force/velocity and the latter in units of time, so that it can more easily be used as a thermostat.
18.208.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is modifying forces. Default is the outermost level.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command. This fix should only be used with damped dynamics minimizers that allow for non-conservative forces. See the min_style command for details.

18.214.3 Description

Bound the simulation domain on one or more of its faces with a flat wall that interacts with the atoms in the group by generating a force on the atom in a direction perpendicular to the wall. The energy of wall-particle interactions depends on the style.

For style `wall/lj93`, the energy $E$ is given by the 9/3 potential:

$$E = \epsilon \left[ \frac{2}{15} \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^3 \right] \quad r < r_c$$

For style `wall/lj126`, the energy $E$ is given by the 12/6 potential:

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c$$

For style `wall/lj1043`, the energy $E$ is given by the 10/4/3 potential:

$$E = 2\pi\epsilon \left[ \frac{2}{5} \left( \frac{\sigma}{r} \right)^{10} - \left( \frac{\sigma}{r} \right)^4 - \frac{\sqrt{2}\sigma^3}{3 \left( r + \left(0.61/\sqrt{2}\right)\sigma \right)^3} \right] \quad r < r_c$$

For style `wall/colloid`, the energy $E$ is given by an integrated form of the pair_style colloid potential:

$$E = \epsilon \left[ \frac{\sigma^6}{7500} \left( \frac{6R-D}{D^7} + \frac{D+8R}{(D+2R)^7} \right) - \frac{1}{6} \left( \frac{2R(D+R)+D(D+2R)\ln D - \ln(D+2R)}{D(D+2R)} \right) \right] \quad r < r_c$$

For style `wall/harmonic`, the energy $E$ is given by a harmonic spring potential:

$$E = \epsilon \left( r - r_c \right)^2 \quad r < r_c$$
For style wall/morse, the energy $E$ is given by a Morse potential:

$$E = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c$$

In all cases, $r$ is the distance from the particle to the wall at position coord, and $r_c$ is the cutoff distance at which the particle and wall no longer interact. The energy of the wall potential is shifted so that the wall-particle interaction energy is 0.0 at the cutoff distance.

Up to 6 walls or faces can be specified in a single command: xlo, xhi, ylo, yhi, zlo, zhi. A lo face interacts with particles near the lower side of the simulation box in that dimension. A hi face interacts with particles near the upper side of the simulation box in that dimension.

The position of each wall can be specified in one of 3 ways: as the EDGE of the simulation box, as a constant value, or as a variable. If EDGE is used, then the corresponding boundary of the current simulation box is used. If a numeric constant is specified then the wall is placed at that position in the appropriate dimension (x, y, or z). In both the EDGE and constant cases, the wall will never move. If the wall position is a variable, it should be specified as v_name, where name is an equal-style variable name. In this case the variable is evaluated each timestep and the result becomes the current position of the reflecting wall. Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall position. See examples below.

For the wall/lj93 and wall/lj126 and wall/lj1043 styles, $\epsilon$ and $\sigma$ are the usual Lennard-Jones parameters, which determine the strength and size of the particle as it interacts with the wall. Epsilon has energy units. Note that this $\epsilon$ and $\sigma$ may be different than any $\epsilon$ or $\sigma$ values defined for a pair style that computes particle-particle interactions.

The wall/lj93 interaction is derived by integrating over a 3d half-lattice of Lennard-Jones 12/6 particles. The wall/lj126 interaction is effectively a harder, more repulsive wall interaction. The wall/lj1043 interaction is yet a different form of wall interaction, described in Magda et al in (Magda).

For the wall/colloid style, $R$ is the radius of the colloid particle, $D$ is the distance from the surface of the colloid particle to the wall ($r$-R), and $\sigma$ is the size of a constituent LJ particle inside the colloid particle and wall. Note that the cutoff distance $R_c$ in this case is the distance from the colloid particle center to the wall. The prefactor $\epsilon$ can be thought of as an effective Hamaker constant with energy units for the strength of the colloid-wall interaction. More specifically, the $\epsilon$ pre-factor is $4\pi^2 \rho_{wall}\rho_{colloid}\sigma^6$, where $\epsilon$ and $\sigma$ are the LJ parameters for the constituent LJ particles. $\rho_{wall}$ and $\rho_{colloid}$ are the number density of the constituent particles, in the wall and colloid respectively, in units of 1/volume.

The wall/colloid interaction is derived by integrating over constituent LJ particles of size $\sigma$ within the colloid particle and a 3d half-lattice of Lennard-Jones 12/6 particles of size $\sigma$ in the wall. As mentioned in the preceding paragraph, the density of particles in the wall and colloid can be different, as specified by the $\epsilon$ pre-factor.

For the wall/harmonic style, $\epsilon$ is effectively the spring constant $K$, and has units (energy/distance^2). The input parameter $\sigma$ is ignored. The minimum energy position of the harmonic spring is at the cutoff. This is a repulsive-only spring since the interaction is truncated at the cutoff.

For the wall/morse style, the three parameters are in this order: $D_0$, the depth of the potential, $\alpha$ the width parameter, and $r_0$ the location of the minimum. $D_0$ has energy units, $\alpha$ inverse distance units, and $r_0$ distance units.

For any wall, the $\epsilon$ and/or $\sigma$ and/or $\alpha$ parameter can be specified as an equal-style variable, in which case it should be specified as v_name, where name is the variable name. As with a variable wall position, the variable is evaluated each timestep and the result becomes the current epsilon or sigma of the wall. Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall interaction.

Note: For all of the styles, you must insure that $r$ is always $> 0$ for all particles in the group, or LAMMPS will generate an error. This means you cannot start your simulation with particles at the wall position coord ($r = 0$) or with particles on the wrong side of the wall ($r < 0$). For the wall/lj93 and wall/lj126 styles, the energy of the wall/particle interaction (and hence the force on the particle) blows up as $r \to 0$. The wall/colloid style is even more restrictive, since the energy blows up as $D = r$-R $\to 0$. This means the finite-size particles of radius $R$ must be a distance larger.
than $R$ from the wall position $coord$. The *harmonic* style is a softer potential and does not blow up as $r \to 0$, but you must use a large enough $\epsilon$ that particles always remain on the correct side of the wall ($r > 0$).

The *units* keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant or variable is used. It is not relevant when *EDGE* is used to specify a face position. In the variable case, the variable is assumed to produce a value compatible with the *units* setting you specify.

A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacings.

The *fld* keyword can be used with a *yes* setting to invoke the wall constraint before pairwise interactions are computed. This allows an implicit FLD model using *pair_style lubricateU* to include the wall force in its calculations. If the setting is *no*, wall forces are imposed after pairwise interactions, in the usual manner.

The *pbc* keyword can be used with a *yes* setting to allow walls to be specified in a periodic dimension. See the *boundary* command for options on simulation box boundaries. The default for *pbc* is *no*, which means the system must be non-periodic when using a wall. But you may wish to use a periodic box. E.g. to allow some particles to interact with the wall via the fix group-ID, and others to pass through it and wrap around a periodic box. In this case you should insure that the wall is sufficiently far enough away from the box boundary. If you do not, then particles may interact with both the wall and with periodic images on the other side of the box, which is probably not what you want.

Here are examples of variable definitions that move the wall position in a time-dependent fashion using equal-style variables. The wall interaction parameters (epsilon, sigma) could be varied with additional variable definitions.

```
variable ramp equal ramp(0,10)
fix 1 all wall xlo v_ramp 1.0 1.0 2.5
variable linear equal vdisplace(0,20)
fix 1 all wall xlo v_linear 1.0 1.0 2.5
variable wiggle equal swiggle(0.0,5.0,3.0)
fix 1 all wall xlo v_wiggle 1.0 1.0 2.5
variable wiggle equal cwiggle(0.0,5.0,3.0)
fix 1 all wall xlo v_wiggle 1.0 1.0 2.5
```

The *ramp(lo,hi)* function adjusts the wall position linearly from $lo$ to $hi$ over the course of a run. The *vdisplace(c0,velocity)* function does something similar using the equation $position = c0 + velocity*delta$, where $delta$ is the elapsed time.

The *swiggle(c0,A,period)* function causes the wall position to oscillate sinusoidally according to this equation, where $omega = 2\ PI/period$:

$position = c0 + A \sin(omega*delta)$

The *cwiggle(c0,A,period)* function causes the wall position to oscillate sinusoidally according to this equation, which will have an initial wall velocity of 0.0, and thus may impose a gentler perturbation on the particles:

$position = c0 + A \ (1 - \cos(omega*delta))$
18.214.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the energy of interaction between atoms and each wall to the system’s potential energy as part of thermodynamic output.

The fix_modify virial option is supported by this fix to add the contribution due to the interaction between atoms and each wall to the system’s virial as part of thermodynamic output. The default is virial no.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar energy and a global vector of forces, which can be accessed by various output commands. Note that the scalar energy is the sum of interactions with all defined walls. If you want the energy on a per-wall basis, you need to use multiple fix wall commands. The length of the vector is equal to the number of walls defined by the fix. Each vector value is the normal force on a specific wall. Note that an outward force on a wall will be a negative value for lo walls and a positive value for hi walls. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

Note: If you want the atom/wall interaction energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

18.215.3 Description

This fix is for use with 2d models of body particles of style \textit{rounded/polygon}. It bounds the simulation domain with wall(s). All particles in the group interact with the wall when they are close enough to touch it. The nature of the interaction between the wall and the polygon particles is the same as that between the polygon particles themselves, which is similar to a Hookean potential. See the \textit{Howto body} doc page for more details on using body particles.

The parameters $k_n$, $c_n$, $c_t$ have the same meaning and units as those specified with the \textit{pair_style body/rounded/polygon} command.

The \textit{wallstyle} can be planar or cylindrical. The 2 planar options specify a pair of walls in a dimension. Wall positions are given by \textit{lo} and \textit{hi}. Either of the values can be specified as NULL if a single wall is desired. For a \textit{zcylinder} \textit{wallstyle}, the cylinder's axis is at $x = y = 0.0$, and the radius of the cylinder is specified.

Optionally, the wall can be moving, if the \textit{wiggle} keyword is appended.

For the \textit{wiggle} keyword, the wall oscillates sinusoidally, similar to the oscillations of particles which can be specified by the \textit{fix move} command. This is useful in packing simulations of particles. The arguments to the \textit{wiggle} keyword specify a dimension for the motion, as well as it's \textit{amplitude} and \textit{period}. Note that if the dimension is in the plane of the wall, this is effectively a shearing motion. If the dimension is perpendicular to the wall, it is more of a shaking motion. A \textit{zcylinder} wall can only be wiggled in the $z$ dimension.

Each timestep, the position of a wiggled wall in the appropriate \textit{dim} is set according to this equation:

\[ \text{position} = \text{coord} + A - A \cos(\omega \delta) \]

where \textit{coord} is the specified initial position of the wall, $A$ is the \textit{amplitude}, $\omega$ is $2 \pi / \text{period}$, and $\delta$ is the time elapsed since the fix was specified. The velocity of the wall is set to the derivative of this expression.

18.215.4 Restart, fix_modify, output, run start/stop, minimize info

None of the \textit{fix_modify} options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various \textit{output commands}. No parameter of this fix can be used with the \textit{start/stop} keywords of the \textit{run} command. This fix is not invoked during \textit{energy minimization}.

18.215.5 Restrictions

This fix is part of the \textit{BODY package}. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

Any dimension (xy) that has a wall must be non-periodic.

18.216.3 Description

This fix is for use with 3d models of body particles of style *rounded/polyhedron*. It bounds the simulation domain with wall(s). All particles in the group interact with the wall when they are close enough to touch it. The nature of the interaction between the wall and the polygon particles is the same as that between the polygon particles themselves, which is similar to a Hookean potential. See the *Howto body* doc page for more details on using body particles.

The parameters $k_n$, $c_n$, $c_t$ have the same meaning and units as those specified with the *pair_style body/rounded/polyhedron* command.

The *wallstyle* can be planar or cylindrical. The 3 planar options specify a pair of walls in a dimension. Wall positions are given by $lo$ and $hi$. Either of the values can be specified as NULL if a single wall is desired.

Optionally, the wall can be moving, if the *wiggle* keyword is appended.

For the *wiggle* keyword, the wall oscillates sinusoidally, similar to the oscillations of particles which can be specified by the *fix move* command. This is useful in packing simulations of particles. The arguments to the *wiggle* keyword specify a dimension for the motion, as well as it’s *amplitude* and *period*. Note that if the dimension is in the plane of the wall, this is effectively a shearing motion. If the dimension is perpendicular to the wall, it is more of a shaking motion.

Each timestep, the position of a wiggled wall in the appropriate *dim* is set according to this equation:

$$\text{position} = \text{coord} + A - A \cos (\omega \times \delta)$$

where $\text{coord}$ is the specified initial position of the wall, $A$ is the *amplitude*, $\omega$ is $2 \pi / \text{period}$, and $\delta$ is the time elapsed since the fix was specified. The velocity of the wall is set to the derivative of this expression.

18.216.4 Restart, fix modify, output, run start/stop, minimize info

None of the *fix modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

18.216.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

```
18.218.3 Description

Fix \textit{wall/ees} bounds the simulation domain on one or more of its faces with a flat wall that interacts with the ellipsoidal atoms in the group by generating a force on the atom in a direction perpendicular to the wall and a torque parallel with the wall. The energy of wall-particle interactions $E$ is given by:

$$ E = \epsilon \left[ \frac{2\sigma_{LJ}^2 (7r^5 + 14r^3 \sigma_n^2 + 3r \sigma_n^4)}{945 (r^2 - \sigma_n^2)^7} - \frac{\sigma_{LJ}^6}{12 \sigma_n^6} \left( \frac{2r^2 \sigma_n^3 + \sigma_n^2 (r^2 - \sigma_n^2) \log \left[ \frac{r - \sigma_n}{r + \sigma_n} \right]}{r^2 - \sigma_n^2} \right) \right] \quad \sigma_n < r < r_c $$

Introduced by Babadi and Ejtehadi in \textit{(Babadi)}. Here, $r$ is the distance from the particle to the wall at position \textit{coord}, and $R_c$ is the \textit{cutoff} distance at which the particle and wall no longer interact. Also, $\sigma_n$ is the distance between center of ellipsoid and the nearest point of its surface to the wall as shown below.

Details of using this command and specifications are the same as \textit{fix/wall} command. You can also find an example in USER/ees/ under examples/s directory.

The prefactor $\epsilon$ can be thought of as an effective Hamaker constant with energy units for the strength of the ellipsoid-wall interaction. More specifically, the $\epsilon$ pre-factor is

$$ 8\pi^2 \rho_{wall} \rho_{ellipsoid} \epsilon \sigma_a \sigma_b \sigma_c $$

where $\epsilon$ is the LJ energy parameter for the constituent LJ particles and $\sigma_a$, $\sigma_b$, and $\sigma_c$ are the radii of the ellipsoidal particles. $\rho_{wall}$ and $\rho_{ellipsoid}$ are the number density of the constituent particles, in the wall and ellipsoid respectively, in units of $1$/volume.

\textbf{Note:} You must insure that $r$ is always bigger than $\sigma_n$ for all particles in the group, or LAMMPS will generate an error. This means you cannot start your simulation with particles touching the wall position \textit{coord} ($r = \sigma_n$) or with particles penetrating the wall ($0 < r < \sigma_n$) or with particles on the wrong side of the wall ($r < 0$).
Fix `wall/region/ees` treats the surface of the geometric region defined by the `region-ID` as a bounding wall which interacts with nearby ellipsoidal particles according to the EES potential introduced above.

Other details of this command are the same as for the `fix wall/region` command. One may also find an example of using this fix in the examples/USER/misc/ees/ directory.

### 18.218.4 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

This fix requires that atoms be ellipsoids as defined by the `atom_style ellipsoid` command.

18.219.3 Description

Bound the simulation domain of a granular system with a frictional wall. All particles in the group interact with the wall when they are close enough to touch it.

The nature of the wall/particle interactions are determined by the fstyle setting. It can be any of the styles defined by the pair_style gran/* or the more general pair_style granular commands. Currently the options are hooke, hooke/history, or hertz/history for the former, and granular with all the possible options of the associated pair_coeff command for the latter. The equation for the force between the wall and particles touching it is the same as the corresponding equation on the pair_style gran/* and pair_style granular doc pages, in the limit of one of the two particles going to infinite radius and mass (flat wall). Specifically, \( \delta = r - r = \text{overlap of particle with wall} \), \( m_{\text{eff}} = \text{mass of particle} \), and the effective radius of contact = \( R_i R_j / R_i + R_j \) is set to the radius of the particle.

The parameters \( K_n, K_t, \gamma_n, \gamma_t, \chi, \) and dampflag have the same meaning and units as those specified with the pair_style gran/* commands. This means a NULL can be used for either \( K_t \) or \( \gamma_t \) as described on that
page. If a NULL is used for $K_t$, then a default value is used where $K_t = 2/7 \, K_n$. If a NULL is used for $\gamma_t$, then a default value is used where $\gamma_t = 1/2 \, \gamma_n$.

All the model choices for cohesion, tangential friction, rolling friction and twisting friction supported by the pair_style granular through its pair_coeff command are also supported for walls. These are discussed in greater detail on the doc page for pair_style granular.

Note that you can choose a different force styles and/or different values for the wall/particle coefficients than for particle/particle interactions. E.g. if you wish to model the wall as a different material.

Note: As discussed on the doc page for pair_style gran/*, versions of LAMMPS before 9Jan09 used a different equation for Hertzian interactions. This means Hertzian wall/particle interactions have also changed. They now include a $\sqrt{\text{radius}}$ term which was not present before. Also the previous versions used $K_n$ and $K_t$ from the pairwise interaction and hardwired dampflag to 1, rather than letting them be specified directly. This means you can set the values of the wall/particle coefficients appropriately in the current code to reproduce the results of a previous Hertzian monodisperse calculation. For example, for the common case of a monodisperse system with particles of diameter 1, $K_n$, $K_t$, $\gamma_n$, and $\gamma_s$ should be set $\sqrt{2.0}$ larger than they were previously.

The effective mass $m_{\text{eff}}$ in the formulas listed on the pair_style granular doc page is the mass of the particle for particle/wall interactions (mass of wall is infinite). If the particle is part of a rigid body, its mass is replaced by the mass of the rigid body in those formulas. This is determined by searching for a fix rigid command (or its variants).

The wallstyle can be planar or cylindrical. The 3 planar options specify a pair of walls in a dimension. Wall positions are given by $lo$ and $hi$. Either of the values can be specified as NULL if a single wall is desired. For a zcylinder wallstyle, the cylinder’s axis is at $x = y = 0.0$, and the radius of the cylinder is specified.

Optionally, the wall can be moving, if the wiggle or shear keywords are appended. Both keywords cannot be used together.

For the wiggle keyword, the wall oscillates sinusoidally, similar to the oscillations of particles which can be specified by the fix move command. This is useful in packing simulations of granular particles. The arguments to the wiggle keyword specify a dimension for the motion, as well as it’s amplitude and period. Note that if the dimension is in the plane of the wall, this is effectively a shearing motion. If the dimension is perpendicular to the wall, it is more of a shaking motion. A zcylinder wall can only be wigged in the z dimension.

Each timestep, the position of a wiggled wall in the appropriate dim is set according to this equation:

$$\text{position} = \text{coord} + A - A \cos (\omega \delta)$$

where $\text{coord}$ is the specified initial position of the wall, $A$ is the amplitude, $\omega$ is $2 \pi / \text{period}$, and $\delta$ is the time elapsed since the fix was specified. The velocity of the wall is set to the derivative of this expression.

For the shear keyword, the wall moves continuously in the specified dimension with velocity vshear. The dimension must be tangential to walls with a planar wallstyle, e.g. in the y or z directions for an xplane wall. For zcylinder walls, a dimension of z means the cylinder is moving in the z-direction along it’s axis. A dimension of $x$ or $y$ means the cylinder is spinning around the z-axis, either in the clockwise direction for $\text{vshear} > 0$ or counter-clockwise for $\text{vshear} < 0$. In this case, $\text{vshear}$ is the tangential velocity of the wall at whatever radius has been defined.
18.219.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the shear friction state of atoms interacting with the wall to binary restart files, so that a simulation can continue correctly if granular potentials with shear “history” effects are being used. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

If the contacts option is used, this fix generates a per-atom array with 8 columns as output, containing the contact information for owned particles (nlocal on each processor). All columns in this per-atom array will be zero if no contact has occurred. The values of these columns are listed in the following table:

<table>
<thead>
<tr>
<th>Index</th>
<th>Value</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1.0 if particle is in contact with wall, 0.0 otherwise</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Force ( f_x ) exerted on the wall</td>
<td>force units</td>
</tr>
<tr>
<td>3</td>
<td>Force ( f_y ) exerted on the wall</td>
<td>force units</td>
</tr>
<tr>
<td>4</td>
<td>Force ( f_z ) exerted on the wall</td>
<td>force units</td>
</tr>
<tr>
<td>5</td>
<td>( \Delta x ) between wall surface and particle</td>
<td>distance units</td>

18.220.3 Description

Treat the surface of the geometric region defined by the region-ID as a bounding frictional wall which interacts with nearby finite-size granular particles when they are close enough to touch the wall. See the fix wall/region and fix wall/gran commands for related kinds of walls for non-granular particles and simpler wall geometries, respectively.

Here are snapshots of example models using this command. Corresponding input scripts can be found in examples/granregion. Movies of these simulations are here on the Movies page of the LAMMPS web site.
The distance between a particle and the region boundary is the distance to the nearest point on the region surface. The force the wall exerts on the particle is along the direction between that point and the particle center, which is the direction normal to the surface at that point. Note that if the region surface is comprised of multiple “faces”, then each face can exert a force on the particle if it is close enough. E.g. for region_style block, a particle in the interior, near a corner of the block, could feel wall forces from 1, 2, or 3 faces of the block.

Regions are defined using the region command. Note that the region volume can be interior or exterior to the bounding surface, which will determine in which direction the surface interacts with particles, i.e. the direction of the surface normal. The exception to this is if one or more open options are specified for the region command, in which case particles interact with both the interior and exterior surfaces of regions.

Regions can either be primitive shapes (block, sphere, cylinder, etc) or combinations of primitive shapes specified via the union or intersect region styles. These latter styles can be used to construct particle containers with complex shapes.

Regions can also move dynamically via the region command keywords (move) and rotate, or change their shape by use of variables as inputs to the region command. If such a region is used with this fix, then the region surface will move in time in the corresponding manner.

**Note:** As discussed on the region command doc page, regions in LAMMPS do not get wrapped across periodic boundaries. It is up to you to ensure that the region location with respect to periodic or non-periodic boundaries is specified appropriately via the region and boundary commands when using a region as a wall that bounds particle motion.

**Note:** For primitive regions with sharp corners and/or edges (e.g. a block or cylinder), wall/particle forces are computed accurately for both interior and exterior regions. For union and intersect regions, additional sharp corners and edges may be present due to the intersection of the surfaces of 2 or more primitive volumes. These corners and edges can be of two types: concave or convex. Concave points/edges are like the corners of a cube as seen by particles in the interior of a cube. Wall/particle forces around these features are computed correctly. Convex points/edges are
like the corners of a cube as seen by particles exterior to the cube, i.e. the points jut into the volume where particles
are present. LAMMPS does NOT compute the location of these convex points directly, and hence wall/particle forces
in the cutoff volume around these points suffer from inaccuracies. The basic problem is that the outward normal of
the surface is not continuous at these points. This can cause particles to feel no force (they don’t “see” the wall) when
in one location, then move a distance epsilon, and suddenly feel a large force because they now “see” the wall. In
a worst-case scenario, this can blow particles out of the simulation box. Thus, as a general rule you should not use
the fix wall/gran/region command with union or intersect regions that have convex points or edges resulting from the
union/intersection (convex points/edges in the union/intersection due to a single sub-region are still OK).

Note: Similarly, you should not define union or intersect regions for use with this command that share an overlapping
common face that is part of the overall outer boundary (interior boundary is OK), even if the face is smooth. E.g. two
regions of style block in a union region, where the two blocks overlap on one or more of their faces. This is because
LAMMPS discards points that are part of multiple sub-regions when calculating wall/particle interactions, to avoid
double-counting the interaction. Having two coincident faces could cause the face to become invisible to the particles.
The solution is to make the two faces differ by epsilon in their position.

The nature of the wall/particle interactions are determined by the fstyle setting. It can be any of the styles defined by the
pair_style gran/* or the more general pair_style granular commands. Currently the options are hooke, hooke/history,
or hertz/history for the former, and granular with all the possible options of the associated pair_coeff command for the
latter. The equation for the force between the wall and particles touching it is the same as the corresponding equation
on the pair_style gran/* and pair_style granular doc pages, but the effective radius is calculated using the radius of the
particle and the radius of curvature of the wall at the contact point.

Specifically, \( \delta = \text{radius} - r = \text{overlap of particle with wall} \), \( m_{\text{eff}} = \text{mass of particle} \), and \( R_i/R_j/R_i+R_j \) is the effective
radius, with \( R_j \) replaced by the radius of curvature of the wall at the contact point. The radius of curvature can be
negative for a concave wall section, e.g. the interior of cylinder. For a flat wall, \( \delta = \text{radius} - r = \text{overlap of particle}
with wall} \), \( m_{\text{eff}} = \text{mass of particle} \), and the effective radius of contact is just the radius of the particle.

The parameters \( K_n \), \( K_t \), \( \gamma_n \), \( \gamma_t \), \( xmu \) and dampflag have the same meaning and units as those specified
with the pair_style gran/* commands. This means a NULL can be used for either \( K_t \) or \( \gamma_t \) as described on that
page. If a NULL is used for \( K_t \), then a default value is used where \( K_t = 2/7 \) \( K_n \). If a NULL is used for \( \gamma_t \), then
a default value is used where \( \gamma_t = 1/2 \) \( \gamma_n \).

All the model choices for cohesion, tangential friction, rolling friction and twisting friction supported by the pair_style
granular through its pair_coeff command are also supported for walls. These are discussed in greater detail on the
doc page for pair_style granular.

Note that you can choose a different force styles and/or different values for the 6 wall/particle coefficients than for
particle/particle interactions. E.g. if you wish to model the wall as a different material.

18.220.4 Restart, fix_modify, output, run start/stop, minimize info

Similar to fix wall/gran command, this fix writes the shear friction state of atoms interacting with the wall to binary
restart files, so that a simulation can continue correctly if granular potentials with shear “history” effects are being
used. This fix also includes info about a moving region in the restart file. See the read_restart command for info
on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an
uninterrupted fashion.

Note: Information about region definitions is NOT included in restart files, as discussed on the read_restart doc page.
So you must re-define your region and if it is a moving region, define its motion attributes in a way that is consistent
with the simulation that wrote the restart file. In particular, if you want to change the region motion attributes (e.g. its
velocity), then you should ensure the position/orientation of the region at the initial restart timestep is the same as it
was on the timestep the restart file was written. If this is not possible, you may need to ignore info in the restart file by
defining a new fix wall/gran/region command in your restart script, e.g. with a different fix ID. Or if you want to keep the shear history info but discard the region motion information, you can use the same fix ID for fix wall/gran/region, but assign it a region with a different region ID.

If the **contacts** option is used, this fix generates a per-atom array with 8 columns as output, containing the contact information for owned particles (nlocal on each processor). All columns in this per-atom array will be zero if no contact has occurred. The values of these columns are listed in the following table:

<table>
<thead>
<tr>
<th>Index</th>
<th>Value</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1.0 if particle is in contact with wall, 0.0 otherwise</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Force $f_x$ exerted on the wall</td>
<td>force units</td>
</tr>
<tr>
<td>3</td>
<td>Force $f_y$ exerted on the wall</td>
<td>force units</td>
</tr>
<tr>
<td>4</td>
<td>Force $f_z$ exerted on the wall</td>
<td>force units</td>
</tr>
<tr>
<td>5</td>
<td>$\Delta x$ between wall surface and particle</td>
<td>distance units</td>
</tr>
<tr>
<td>6</td>
<td>$\Delta y$ between wall surface and particle</td>
<td>distance units</td>

```

- ID, group-ID are documented in **fix** command
- wall/piston = style name of this fix command
- face = *zlo*
- zero or more keyword/value pairs may be appended
- keyword = *pos or vel or ramp or units*
pos args = z
    z = z coordinate at which the piston begins (distance units)
vel args = vz
    vz = final velocity of the piston (velocity units)
ramp = use a linear velocity ramp from 0 to vz
temp args = target damp seed extent
    target = target velocity for region immediately ahead of the piston
damp = damping parameter (time units)
seed = random number seed for langevin kicks
extent = extent of thermostatted region (distance units)
units value = lattice or box
    lattice = the wall position is defined in lattice units
    box = the wall position is defined in simulation box units

18.221.2 Examples

fix xwalls all wall/piston zlo
fix walls all wall/piston zlo pos 1.0 vel 10.0 units box
fix top all wall/piston zlo vel 10.0 ramp

18.221.3 Description

Bound the simulation with a moving wall which reflect particles in the specified group and drive the system with an effective infinite-mass piston capable of driving shock waves.

A momentum mirror technique is used, which means that if an atom (or the wall) moves such that an atom is outside the wall on a timestep by a distance delta (e.g. due to fix nve), then it is put back inside the face by the same delta, and the velocity relative to the moving wall is flipped in z. For instance, a stationary particle hit with a piston wall with velocity vz, will end the timestep with a velocity of 2*vz.

Currently the face keyword can only be zlo. This creates a piston moving in the positive z direction. Particles with z coordinate less than the wall position are reflected to a z coordinate greater than the wall position. If the piston velocity is vpz and the particle velocity before reflection is vzi, the particle velocity after reflection is -vzi + 2*vpz.

The initial position of the wall can be specified by the pos keyword.

The final velocity of the wall can be specified by the vel keyword

The ramp keyword will cause the wall/piston to adjust the velocity linearly from zero velocity to vel over the course of the run. If the ramp keyword is omitted then the wall/piston moves at a constant velocity defined by vel.

The temp keyword will cause the region immediately in front of the wall/piston to be thermostatted with a Langevin thermostat. This region moves with the piston. The damping and kicking are measured in the reference frame of the piston. So, a temperature of zero would mean all particles were moving at exactly the speed of the wall/piston.

The units keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used.

A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacings.
18.221.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

18.221.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The face that has the wall/piston must be boundary type ‘s’ (shrink-wrapped). The opposing face can be any boundary type other than periodic.

A wall/piston should not be used with rigid bodies such as those defined by a “fix rigid” command. This is because the wall/piston displaces atoms directly rather than exerting a force on them.

18.221.6 Related commands

fix top all wall/reflect zhi v_pressdown
```

18.222.3 Description

Bound the simulation with one or more walls which reflect particles in the specified group when they attempt to move through them.

Reflection means that if an atom moves outside the wall on a timestep by a distance delta (e.g. due to fix nve), then it is put back inside the face by the same delta, and the sign of the corresponding component of its velocity is flipped.

When used in conjunction with fix nve and run_style verlet, the resultant time-integration algorithm is equivalent to the primitive splitting algorithm (PSA) described by Bond. Because each reflection event divides the corresponding timestep asymmetrically, energy conservation is only satisfied to O(dt), rather than to O(dt^2) as it would be for velocity-Verlet integration without reflective walls.

Up to 6 walls or faces can be specified in a single command: xlo, xhi, ylo, yhi, zlo, zhi. A lo face reflects particles that move to a coordinate less than the wall position, back in the hi direction. A hi face reflects particles that move to a coordinate higher than the wall position, back in the lo direction.

The position of each wall can be specified in one of 3 ways: as the EDGE of the simulation box, as a constant value, or as a variable. If EDGE is used, then the corresponding boundary of the current simulation box is used. If a numeric constant is specified then the wall is placed at that position in the appropriate dimension (x, y, or z). In both the EDGE and constant cases, the wall will never move. If the wall position is a variable, it should be specified as v_name, where name is an equal-style variable name. In this case the variable is evaluated each timestep and the result becomes the current position of the reflecting wall. Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall position.

The units keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant or variable is used. It is not relevant when EDGE is used to specify a face position. In the variable case, the variable is assumed to produce a value compatible with the units setting you specify.

A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacings.

Here are examples of variable definitions that move the wall position in a time-dependent fashion using equal-style variables.

```
variable ramp equal ramp(0,10)
fix 1 all wall/reflect xlo v_ramp

variable linear equal vdisplace(0,20)
fix 1 all wall/reflect xlo v_linear

variable wiggle equal swiggle(0.0,5.0,3.0)
fix 1 all wall/reflect xlo v_wiggle

variable wiggle equal cwiggle(0.0,5.0,3.0)
fix 1 all wall/reflect xlo v_wiggle
```
The `ramp(lo,hi)` function adjusts the wall position linearly from `lo` to `hi` over the course of a run. The `vdisplace(c0,velocity)` function does something similar using the equation \( \text{position} = c0 + \text{velocity} \times \text{delta} \), where `delta` is the elapsed time.

The `swiggle(c0,A,period)` function causes the wall position to oscillate sinusoidally according to this equation, where \( \omega = \frac{2 \pi}{\text{period}} \):

\[
\text{position} = c0 + A \sin(\omega \times \text{delta})
\]

The `cwiggle(c0,A,period)` function causes the wall position to oscillate sinusoidally according to this equation, which will have an initial wall velocity of 0.0, and thus may impose a gentler perturbation on the particles:

\[
\text{position} = c0 + A \left(1 - \cos(\omega \times \text{delta})\right)
\]

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

**18.222.4 Restart, fix_modify, output, run start/stop, minimize info**

No information about this fix is written to `binary restart files`. None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various `output commands`. No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during `energy minimization`.

**18.222.5 Restrictions**

Any dimension (xyz) that has a reflecting wall must be non-periodic.

A reflecting wall should not be used with rigid bodies such as those defined by a “fix rigid” command. This is because the wall/reflect displaces atoms directly rather than exerts a force on them. For rigid bodies, use a soft wall instead, such as `fix wall/lj93`. LAMMPS will flag the use of a rigid fix with fix wall/reflect with a warning, but will not generate an error.

18.223. fix wall/reflect/stochastic command 1445
18.223.3 Description

Bound the simulation with one or more walls which reflect particles in the specified group when they attempt to move through them.

Reflection means that if an atom moves outside the wall on a timestep (e.g. due to the fix nve command), then it is put back inside the wall with a changed velocity.

This fix models treats the wall as a moving solid boundary with a finite temperature, which can exchange energy with particles that collide with it. This is different than the simpler fix wall/reflect command which models mirror reflection. For this fix, the post collision velocity of each particle is treated stochastically. The randomness can come from many sources: thermal motion of the wall atoms, surface roughness, etc. Three stochastic reflection models are currently implemented.

For rstyle `diffusive`, particles are reflected diffusively. Their velocity distribution corresponds to an equilibrium distribution of particles at the wall temperature. No accommodation coefficients are specified.

For rstyle `maxwell`, particle reflection is Maxwellian which means partially diffusive and partially specular (Maxwell). A single accommodation coeff is specified which must be between 0.0 and 1.0 inclusive. It determines the fraction of the collision which is diffusive versus specular. An accommodation coefficient of 1.0 is fully diffusive; a coefficient of 0.0 is fully specular.

For rstyle `cell`, particle collisions are computed by the Cercignani/Lampis model. See CL and To for details. Three accommodations coefficient are specified. Each must be between 0.0 and 1.0 inclusive. Two are velocity accommodation coefficients; one is a normal kinetic energy accommodation. The normal coeff is the one corresponding to the normal of the wall itself. For example if the wall is `ylo` or `yhi`, `accomx` and `accomz` are the tangential velocity accommodation coefficients, and `accomy` is the normal kinetic energy accommodation coefficient.

The optional `units` keyword determines the distance units used to define a wall position. A `box` value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A `lattice` value means the distance units are in lattice spacings. The `lattice` command must have been previously used to define the lattice spacings.

18.223.4 Restrictions

This fix has the same limitations as the fix wall/reflect command. Any dimension (xyz) that has a wall must be non-periodic. It should not be used with rigid bodies such as those defined by the fix rigid command. The wall velocity must lie on the same plane as the wall itself.

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.223.5 Related commands

`fix wall/reflect`
18.223.6 Default

The default for the units keyword is lattice.

18.224 fix wall/region command

18.224.1 Syntax

```
fix ID group-ID wall/region region-ID style args ... cutoff
```

- ID, group-ID are documented in fix command
- wall/region = style name of this fix command
- region-ID = region whose boundary will act as wall
- style = lj93 or lj126 or lj1043 or colloid or harmonic or morse
- args for styles lj93 or lj126 or lj1043 or colloid or harmonic =
  - epsilon = strength factor for wall-particle interaction (energy or energy/ distance^2 units)
  - sigma = size factor for wall-particle interaction (distance units)
- args for style morse =
  - D_0 = depth of the potential (energy units)
  - alpha = width parameter (1/distance units)
  - r_0 = distance of the potential minimum from wall position (distance units)
- cutoff = distance from wall at which wall-particle interaction is cut off (distance units)

fix wall all wall/region mySphere harmonic 1.0 0.0 2.5
fix wall all wall/region box_top morse 1.0 1.0 1.5 3.0
```
18.224.3 Description

Treat the surface of the geometric region defined by the region-ID as a bounding wall which interacts with nearby particles according to the specified style.

The distance between a particle and the surface is the distance to the nearest point on the surface and the force the wall exerts on the particle is along the direction between that point and the particle, which is the direction normal to the surface at that point. Note that if the region surface is comprised of multiple “faces”, then each face can exert a force on the particle if it is close enough. E.g. for region_style block, a particle in the interior, near a corner of the block, could feel wall forces from 1, 2, or 3 faces of the block.

Regions are defined using the region command. Note that the region volume can be interior or exterior to the bounding surface, which will determine in which direction the surface interacts with particles, i.e. the direction of the surface normal. The surface of the region only exerts forces on particles “inside” the region; if a particle is “outside” the region it will generate an error, because it has moved through the wall.

Regions can either be primitive shapes (block, sphere, cylinder, etc) or combinations of primitive shapes specified via the union or intersect region styles. These latter styles can be used to construct particle containers with complex shapes. Regions can also change over time via the region command keywords (move) and rotate. If such a region is used with this fix, then the of region surface will move over time in the corresponding manner.

Note: As discussed on the region command doc page, regions in LAMMPS do not get wrapped across periodic boundaries. It is up to you to insure that periodic or non-periodic boundaries are specified appropriately via the boundary command when using a region as a wall that bounds particle motion. This also means that if you embed a region in your simulation box and want it to repulse particles from its surface (using the “side out” option in the region command), that its repulsive force will not be felt across a periodic boundary.

Note: For primitive regions with sharp corners and/or edges (e.g. a block or cylinder), wall/particle forces are computed accurately for both interior and exterior regions. For union and intersect regions, additional sharp corners and edges may be present due to the intersection of the surfaces of 2 or more primitive volumes. These corners and edges can be of two types: concave or convex. Concave points/edges are like the corners of a cube as seen by particles in the interior of a cube. Wall/particle forces around these features are computed correctly. Convex points/edges are like the corners of a cube as seen by particles exterior to the cube, i.e. the points jut into the volume where particles are present. LAMMPS does NOT compute the location of these convex points directly, and hence wall/particle forces in the cutoff volume around these points suffer from inaccuracies. The basic problem is that the outward normal of the surface is not continuous at these points. This can cause particles to feel no force (they don’t “see” the wall) when in one location, then move a distance epsilon, and suddenly feel a large force because they now “see” the wall. In a worst-case scenario, this can blow particles out of the simulation box. Thus, as a general rule you should not use the fix wall/gran/region command with union or intersect regions that have convex points or edges resulting from the union/intersection (convex points/edges in the union/intersection due to a single sub-region are still OK).

Note: Similarly, you should not define union or intersect regions for use with this command that share an overlapping common face that is part of the overall outer boundary (interior boundary is OK), even if the face is smooth. E.g. two regions of style block in a union region, where the two blocks overlap on one or more of their faces. This is because LAMMPS discards points that are part of multiple sub-regions when calculating wall/particle interactions, to avoid double-counting the interaction. Having two coincident faces could cause the face to become invisible to the particles. The solution is to make the two faces differ by epsilon in their position.

The energy of wall-particle interactions depends on the specified style.
For style \textit{lj93}, the energy \( E \) is given by the 9/3 potential:

\[
E = \epsilon \left[ \frac{2}{15} \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^3 \right] \quad r < r_c
\]

For style \textit{lj126}, the energy \( E \) is given by the 12/6 potential:

\[
E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c
\]

For style \textit{wall/lj1043}, the energy \( E \) is given by the 10/4/3 potential:

\[
E = 2\pi \epsilon \left[ \frac{2}{5} \left( \frac{\sigma}{r} \right)^{10} - \left( \frac{\sigma}{r} \right)^4 - \frac{\sqrt{2} \sigma^3}{3 \left( r + \left( 0.61 / \sqrt{2} \right) \sigma \right)^3} \right] \quad r < r_c
\]

For style \textit{colloid}, the energy \( E \) is given by an integrated form of the \textit{pair_style colloid} potential:

\[
E = \epsilon \left[ \frac{6R-D}{7560} \left( \frac{D+8R}{D+2R} \right)^2 + \frac{D+8R}{D+2R} \ln \left( \frac{D+8R}{D+2R} \right) \right] \quad r < r_c
\]

For style \textit{wall/harmonic}, the energy \( E \) is given by a harmonic spring potential (the distance parameter is ignored):

\[
E = \epsilon \left( r - r_c \right)^2 \quad r < r_c
\]

For style \textit{wall/morse}, the energy \( E \) is given by the Morse potential:

\[
E = D_0 \left[ e^{-2\alpha(r-r_0)} - e^{-\alpha(r-r_0)} \right] \quad r < r_c
\]

Unlike other styles, this requires three parameters (\( D_0 \), \( \alpha \), and \( r_0 \) in this order) instead of two like for the other wall styles.

In all cases, \( r \) is the distance from the particle to the region surface, and \( r_c \) is the cutoff distance at which the particle and surface no longer interact. The cutoff is always the last argument. The energy of the wall potential is shifted so that the wall-particle interaction energy is 0.0 at the cutoff distance.

For a full description of these wall styles, see \texttt{fix_style wall}

\textbf{18.224.4 Restart, fix\_modify, output, run start/stop, minimize info}

No information about this fix is written to \textit{binary restart files}.

The \textit{fix\_modify energy} option is supported by this fix to add the energy of interaction between atoms and the wall to the system’s potential energy as part of \textit{thermodynamic output}.

The \textit{fix\_modify virial} option is supported by this fix to add the contribution due to the interaction between atoms and each wall to the system’s virial as part of \textit{thermodynamic output}. The default is \textit{virial no}

The \textit{fix\_modify respa} option is supported by this fix. This allows to set at which level of the \textit{r-RESPA} integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar energy and a global 3-length vector of forces, which can be accessed by various \textit{output commands}. The scalar energy is the sum of energy interactions for all particles interacting with the wall represented by the region surface. The 3 vector quantities are the \( x,y,z \) components of the total force acting on the wall due to the particles. The scalar and vector values calculated by this fix are “extensive”.

\textbf{18.224. fix wall/region command}
No parameter of this fix can be used with the start/stop keywords of the run command.
The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

**Note:** If you want the atom/wall interaction energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

units value = lattice or box

  lattice = the wall position is defined in lattice units  
  box = the wall position is defined in simulation box units
```
18.225.2 Examples

```bash
fix xwalls all wall/srd xlo EDGE xhi EDGE
fix walls all wall/srd xlo 0.0 ylo 10.0 units box
fix top all wall/srd zhi v_pressdown
```

18.225.3 Description

Bound the simulation with one or more walls which interact with stochastic reaction dynamics (SRD) particles as slip (smooth) or no-slip (rough) flat surfaces. The wall interaction is actually invoked via the `fix srd` command, only on the group of SRD particles it defines, so the group setting for the fix wall/srd command is ignored.

A particle/wall collision occurs if an SRD particle moves outside the wall on a timestep. This alters the position and velocity of the SRD particle and imparts a force to the wall.

The `collision` and `Tsr` settings specified via the `fix srd` command affect the SRD/wall collisions. A `slip` setting for the `collision` keyword means that the tangential component of the SRD particle momentum is preserved. Thus only a normal force is imparted to the wall. The normal component of the new SRD velocity is sampled from a Gaussian distribution at temperature `Tsr`.

For a `noslip` setting of the `collision` keyword, both the normal and tangential components of the new SRD velocity are sampled from a Gaussian distribution at temperature `Tsr`. Additionally, a new tangential direction for the SRD velocity is chosen randomly. This collision style imparts both a normal and tangential force to the wall.

Up to 6 walls or faces can be specified in a single command: `xlo`, `xhi`, `ylo`, `yhi`, `zlo`, `zhi`. A `lo` face reflects particles that move to a coordinate less than the wall position, back in the `hi` direction. A `hi` face reflects particles that move to a coordinate higher than the wall position, back in the `lo` direction.

The position of each wall can be specified in one of 3 ways: as the EDGE of the simulation box, as a constant value, or as a variable. If EDGE is used, then the corresponding boundary of the current simulation box is used. If a numeric constant is specified then the wall is placed at that position in the appropriate dimension (x, y, or z). In both the EDGE and constant cases, the wall will never move. If the wall position is a variable, it should be specified as `v_name`, where name is an `equal-style variable` name. In this case the variable is evaluated each timestep and the result becomes the current position of the reflecting wall. Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall position.

**Note:** Because the trajectory of the SRD particle is tracked as it collides with the wall, you must insure that `r` = distance of the particle from the wall, is always > 0 for SRD particles, or LAMMPS will generate an error. This means you cannot start your simulation with SRD particles at the wall position `coord` (`r` = 0) or with particles on the wrong side of the wall (`r` < 0).

**Note:** If you have 2 or more walls that come together at an edge or corner (e.g. walls in the x and y dimensions), then be sure to set the `overlap` keyword to `yes` in the `fix srd` command, since the walls effectively overlap when SRD particles collide with them. LAMMPS will issue a warning if you do not do this.

**Note:** The walls of this fix only interact with SRD particles, as defined by the `fix srd` command. If you are simulating a mixture containing other kinds of particles, then you should typically use another wall command to act on the other particles. Since SRD particles will be colliding both with the walls and the other particles, it is important to insure that the other particle’s finite extent does not overlap an SRD wall. If you do not do this, you may generate errors when SRD particles end up “inside” another particle or a wall at the beginning of a collision step.
The units keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used. It is not relevant when EDGE or a variable is used to specify a face position.

A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacings.

Here are examples of variable definitions that move the wall position in a time-dependent fashion using equal-style variables.

```plaintext
variable ramp equal ramp(0,10)
fix 1 all wall/srd xlo v_ramp

variable linear equal vdisplace(0,20)
fix 1 all wall/srd xlo v_linear

variable wiggle equal swiggle(0.0,5.0,3.0)
fix 1 all wall/srd xlo v_wiggle

variable wiggle equal cwiggle(0.0,5.0,3.0)
fix 1 all wall/srd xlo v_wiggle
```

The ramp(lo,hi) function adjusts the wall position linearly from lo to hi over the course of a run. The vdisplace(c0,velocity) function does something similar using the equation position = c0 + velocity*delta, where delta is the elapsed time.

The swiggle(c0,A,period) function causes the wall position to oscillate sinusoidally according to this equation, where omega = 2 PI / period:

position = c0 + A sin(omega*delta)

The cwiggle(c0,A,period) function causes the wall position to oscillate sinusoidally according to this equation, which will have an initial wall velocity of 0.0, and thus may impose a gentler perturbation on the particles:

position = c0 + A (1 - cos(omega*delta))

18.225.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes a global array of values which can be accessed by various output commands. The number of rows in the array is equal to the number of walls defined by the fix. The number of columns is 3, for the x,y,z components of force on each wall.

Note that an outward normal force on a wall will be a negative value for lo walls and a positive value for hi walls. The array values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
18.225.5 Restrictions

Any dimension (xyz) that has an SRD wall must be non-periodic.

18.226 fix widom command

18.226.1 Syntax

```
fix ID group-ID widom N M type seed T keyword values ...
```

- ID, group-ID are documented in `fix` command
- `widom` = style name of this fix command
- `N` = invoke this fix every N steps
- `M` = number of Widom insertions to attempt every N steps
- `type` = atom type for inserted atoms (must be 0 if mol keyword used)
- `seed` = random # seed (positive integer)
- `T` = temperature of the system (temperature units)
- zero or more keyword/value pairs may be appended to args

Keyword = mol, region, full_energy, charge, intra_energy

- `mol` value = template-ID
  - template-ID = ID of molecule template specified in a separate `molecule` command
- `region` value = region-ID
  - region-ID = ID of region where Widom insertions are allowed
- `full_energy` = compute the entire system energy when performing Widom insertions
- `charge` value = charge of inserted atoms (charge units)
- `intra_energy` value = intramolecular energy (energy units)
18.226.2 Examples

```
fix 2 gas widom 1 50000 1 19494 2.0
fix 3 water widom 1000 100 0 29494 300.0 mol h2omol full_energy
```

18.226.3 Description

This fix performs Widom insertions of atoms or molecules at the given temperature as discussed in (Frenkel). Specific uses include computation of Henry constants of small molecules in microporous materials or amorphous systems. Every N timesteps the fix attempts M number of Widom insertions of atoms or molecules.

If the mol keyword is used, only molecule insertions are performed. Conversely, if the mol keyword is not used, only atom insertions are performed.

This command may optionally use the region keyword to define an insertion volume. The specified region must have been previously defined with a region command. It must be defined with side = in. Insertion attempts occur only within the specified region. For non-rectangular regions, random trial points are generated within the rectangular bounding box until a point is found that lies inside the region. If no valid point is generated after 1000 trials, no insertion is performed. If an attempted insertion places the atom or molecule center-of-mass outside the specified region, a new attempted insertion is generated. This process is repeated until the atom or molecule center-of-mass is inside the specified region.

Note that neighbor lists are re-built every timestep that this fix is invoked, so you should not set N to be too small. See the neighbor command for details.

When an atom or molecule is to be inserted, its coordinates are chosen at a random position within the current simulation cell or region. Relative coordinates for atoms in a molecule are taken from the template molecule provided by the user. The center of mass of the molecule is placed at the insertion point. The orientation of the molecule is chosen at random by rotating about this point.

Individual atoms are inserted, unless the mol keyword is used. It specifies a template-ID previously defined using the molecule command, which reads a file that defines the molecule. The coordinates, atom types, charges, etc., as well as any bonding and special neighbor information for the molecule can be specified in the molecule file. See the molecule command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

If you wish to insert molecules via the mol keyword, that will have their bonds or angles constrained via SHAKE, use the shake keyword, specifying as its value the ID of a separate fix shake command which also appears in your input script.

Note that fix widom does not use configurational bias MC or any other kind of sampling of intramolecular degrees of freedom. Inserted molecules can have different orientations, but they will all have the same intramolecular configuration, which was specified in the molecule command input.

For atoms, inserted particles have the specified atom type. For molecules, they use the same atom types as in the template molecule supplied by the user.

The excess chemical potential $\mu_{ex}$ is defined as:

$$\mu_{ex} = -kT \ln(< \exp(-(U_{N+1} - U_N)/kT) >)$$

where $k$ is Boltzman’s constant, $T$ is the user-specified temperature, $U_N$ and $U_{N+1}$ is the potential energy of the system with N and N+1 particles.

The full_energy option means that the fix calculates the total potential energy of the entire simulated system, instead of just the energy of the part that is changed. By default, this option is off, in which case only partial energies are computed to determine the energy difference due to the proposed change.
The *full_energy* option is needed for systems with complicated potential energy calculations, including the following:

- long-range electrostatics (kspace)
- many-body pair styles
- hybrid pair styles
- eam pair styles
- tail corrections
- need to include potential energy contributions from other fixes

In these cases, LAMMPS will automatically apply the *full_energy* keyword and issue a warning message.

When the *mol* keyword is used, the *full_energy* option also includes the intramolecular energy of inserted and deleted molecules, whereas this energy is not included when *full_energy* is not used. If this is not desired, the *intra_energy* keyword can be used to define an amount of energy that is subtracted from the final energy when a molecule is inserted, and subtracted from the initial energy when a molecule is deleted. For molecules that have a non-zero intramolecular energy, this will ensure roughly the same behavior whether or not the *full_energy* option is used.

Some fixes have an associated potential energy. Examples of such fixes include: *efield*, *gravity*, *addforce*, *restrain*, and *wall fixes*. For that energy to be included in the total potential energy of the system (the quantity used when performing Widom insertions), you MUST enable the *fix_modify energy* option for that fix. The doc pages for individual *fix* commands specify if this should be done.

Use the *charge* option to insert atoms with a user-specified point charge. Note that doing so will cause the system to become non-neutral. LAMMPS issues a warning when using long-range electrostatics (kspace) with non-neutral systems. See the *compute group/group* documentation for more details about simulating non-neutral systems with kspace on.

### 18.226.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the fix to *binary restart files*. This includes information about the random number generator seed, the next timestep for Widom insertions etc. See the *read_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** For this to work correctly, the timestep must **not** be changed after reading the restart with *reset_timestep*. The fix will try to detect it and stop with an error.

None of the *fix_modify* options are relevant to this fix.

This fix computes a global vector of length 3, which can be accessed by various *output commands*. The vector values are the following global cumulative quantities:

- 1 = average excess chemical potential on each timestep
- 2 = average difference in potential energy on each timestep
- 3 = volume of the insertion region

The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*. 
18.226.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Do not set “neigh_modify once yes” or else this fix will never be called. Reneighboring is required.

Can be run in parallel, but aspects of the GCMC part will not scale well in parallel. Only usable for 3D simulations.

18.226.6 Related commands

fix gcmc fix atom/swap, neighbor, fix deposit, fix evaporate,

18.226.7 Default

The option defaults are mol = no, intra_energy = 0.0 and full_energy = no, except for the situations where full_energy is required, as listed above.

19.1 compute ackland/atom command

19.1.1 Syntax

```
compute ID group-ID ackland/atom keyword/value
```

- ID, group-ID are documented in `compute` command
- ackland/atom = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = `legacy`

```
legacy yes/no = use (yes) or do not use (no) legacy ackland algorithm implementation
```

19.1.2 Examples

```
compute 1 all ackland/atom
compute 1 all ackland/atom legacy yes
```

19.1.3 Description

Defines a computation that calculates the local lattice structure according to the formulation given in *(Ackland)*. Historically, LAMMPS had two, slightly different implementations of the algorithm from the paper. With the `legacy` keyword, it is possible to switch between the pre-2015 (`legacy yes`) and post-2015 implementation (`legacy no`). The post-2015 variant is the default.

In contrast to the `centro-symmetry parameter` this method is stable against temperature boost, because it is based not on the distance between particles but the angles. Therefore statistical fluctuations are averaged out a little more. A comparison with the Common Neighbor Analysis metric is made in the paper.

The result is a number which is mapped to the following different lattice structures:

- 0 = UNKNOWN
- 1 = BCC
- 2 = FCC
- 3 = HCP
• 4 = ICO

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each of which computes this quantity.

19.1.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

19.1.5 Restrictions

This compute is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The per-atom vector values will be unitless since they are the integers defined above.

19.1.6 Related commands

compute centro/atom

19.1.7 Default

The keyword legacy defaults to no.

19.2 compute adf command

19.2.1 Syntax

```
compute ID group-ID adf Nbin itype1 jtype1 ktype1 Rjinner1 Rjouter1 Rkinner1 Rkouter1 ... 
```

• ID, group-ID are documented in compute command
• adf = style name of this compute command
• Nbin = number of ADF bins
• itypeN = central atom type for Nth ADF histogram (see asterisk form below)
• jtypeN = J atom type for Nth ADF histogram (see asterisk form below)
• ktypeN = K atom type for Nth ADF histogram (see asterisk form below)
• RjinnerN = inner radius of J atom shell for Nth ADF histogram (distance units)
• RjouterN = outer radius of J atom shell for Nth ADF histogram (distance units)
• RkinnerN = inner radius of K atom shell for Nth ADF histogram (distance units)
• \( R_{\text{outer}N} \) = outer radius of \( K \) atom shell for \( N \)th ADF histogram (distance units)

• zero or one keyword/value pairs may be appended

• keyword = ordinate

      ordinate value = degree or radian or cosine

      Choose the ordinate parameter for the histogram

19.2.2 Examples

```plaintext
compute 1 fluid adf 32 1 1 1 0.0 1.2 0.0 1.2 &
         1 1 2 0.0 1.2 0.0 1.5 &
         1 2 2 0.0 1.5 0.0 1.5 &
         2 1 1 0.0 1.2 0.0 1.2 &
         2 1 2 0.0 1.5 2.0 3.5 &
         2 2 2 2.0 3.5 2.0 3.5
compute 1 fluid adf 32 1*2 1*2 1*2 0.5 3.5
compute 1 fluid adf 32
```

19.2.3 Description

Define a computation that calculates one or more angular distribution functions (ADF) for a group of particles. Each ADF is calculated in histogram form by measuring the angle formed by a central atom and two neighbor atoms and binning these angles into \( N_{\text{bin}} \) bins. Only neighbors for which \( R_{\text{inner}} < R < R_{\text{outer}} \) are counted, where \( R_{\text{inner}} \) and \( R_{\text{outer}} \) are specified separately for the first and second neighbor atom in each requested ADF.

**Note:** If you have a bonded system, then the settings of `special_bonds` command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the `special_bonds` command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses a neighbor list, it also means those pairs will not be included in the ADF. This does not apply when using long-range coulomb interactions (`coul/long`, `coul/msm`, `coul/wolf` or similar). One way to get around this would be to set `special_bond` scaling factors to very tiny numbers that are not exactly zero (e.g. 1.0e-50). Another workaround is to write a dump file, and use the `rerun` command to compute the ADF for snapshots in the dump file. The rerun script can use a `special_bonds` command that includes all pairs in the neighbor list.

**Note:** If you request any outer cutoff \( R_{\text{outer}} > \) force cutoff, or if no pair style is defined, e.g. the `rerun` command is being used to post-process a dump file of snapshots you must insure ghost atom information out to the largest value of \( R_{\text{outer}} + \) skin is communicated, via the `comm_modify cutoff` command, else the ADF computation cannot be performed, and LAMMPS will give an error message. The skin value is what is specified with the `neighbor` command.

The `itypeN,jtypeN,ktypeN` settings can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or a wild-card asterisk can be used to specify a range of atom types as in the second example above. This takes the form "*" or "*n" or "n*" or "m*n". If \( N \) = the number of atom types, then an asterisk with no numeric values means all types from 1 to \( N \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( N \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive).

If `itypeN`, `jtypeN`, and `ktypeN` are single values, as in the first example above, this means that the ADF is computed where atoms of type `itypeN` are the central atom, and neighbor atoms of type `jtypeN` and `ktypeN` are forming the angle. If any of `itypeN`, `jtypeN`, or `ktypeN` represent a range of values via the wild-card asterisk, as in the second example above, this means that the ADF is computed where atoms of any of the range of types represented by `itypeN` are the
central atom, and the angle is formed by two neighbors, one neighbor in the range of types represented by \(jtypeN\) and another neighbor in the range of types represented by \(ktypeN\).

If no \(itypeN\), \(jtypeN\), \(ktypeN\) settings are specified, then LAMMPS will generate a single ADF for all atoms in the group. The inner cutoff is set to zero and the outer cutoff is set to the force cutoff. If no pair_style is specified, there is no force cutoff and LAMMPS will give an error message. Note that in most cases, generating an ADF for all atoms is not a good thing. Such an ADF is both uninformative and extremely expensive to compute. For example, with liquid water with a 10 A force cutoff, there are 80,000 angles per atom. In addition, most of the interesting angular structure occurs for neighbors that are the closest to the central atom, involving just a few dozen angles.

Angles for each ADF are generated by double-looping over the list of neighbors of each central atom I, just as they would be in the force calculation for a three-body potential such as Stillinger-Weber. The angle formed by central atom I and neighbor atoms J and K is included in an ADF if the following criteria are met:

- atoms I,J,K are all in the specified compute group
- the distance between atoms I,J is between \(Rjinner\) and \(Rjouter\)
- the distance between atoms I,K is between \(Rkinner\) and \(Rkouter\)
- the type of the I atom matches \(itypeN\) (one or a range of types)
- atoms I,J,K are distinct
- the type of the J atom matches \(jtypeN\) (one or a range of types)
- the type of the K atom matches \(ktypeN\) (one or a range of types)

Each unique angle satisfying the above criteria is counted only once, regardless of whether either or both of the neighbor atoms making up the angle appear in both the J and K lists. It is OK if a particular angle is included in more than one individual histogram, due to the way the \(itypeN\), \(jtypeN\), \(ktypeN\) arguments are specified.

The first ADF value for a bin is calculated from the histogram count by dividing by the total number of triples satisfying the criteria, so that the integral of the ADF w.r.t. angle is 1, i.e. the ADF is a probability density function.

The second ADF value is reported as a cumulative sum of all bins up to the current bins, averaged over atoms of type \(itypeN\). It represents the number of angles per central atom with angle less than or equal to the angle of the current bin, analogous to the coordination number radial distribution function.

The \textit{ordinate} optional keyword determines whether the bins are of uniform angular size from zero to 180 (degree), zero to \(\pi\) (radian), or the cosine of the angle uniform in the range \([-1,1]\) (cosine). \textit{cosine} has the advantage of eliminating the \texttt{acos()} function call, which speeds up the compute by 2-3x, and it is also preferred on physical grounds, because the for uniformly distributed particles in 3D, the angular probability density w.r.t. \(d\theta\) is \(\frac{\sin(\theta)}{2}\), while for \(d(\cos(\theta))\), it is \(\frac{1}{2}\). Regardless of which ordinate is chosen, the first column of ADF values is normalized w.r.t. the range of that ordinate, so that the integral is 1.

The simplest way to output the results of the compute adf calculation to a file is to use the \texttt{fix ave/time} command, for example:

\begin{verbatim}
compute myADF all adf 32 2 2 0.5 3.5 0.5 3.5
fix 1 all ave/time 100 1 100 c_myADF[*] file tmp.adf mode vector
\end{verbatim}
19.2.4 Output info

This compute calculates a global array with the number of rows = \(N_{bins}\), and the number of columns = 1 + 2*\(N_{triples}\), where \(N_{triples}\) is the number of I,J,K triples specified. The first column has the bin coordinate (angle-related ordinate at midpoint of bin). Each subsequent column has the two ADF values for a specific set of \((i_{type}N, j_{type}N, k_{type}N)\) interactions, as described above. These values can be used by any command that uses a global values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The array values calculated by this compute are all “intensive”.

The first column of array values is the angle-related ordinate, either the angle in degrees or radians, or the cosine of the angle. Each subsequent pair of columns gives the first and second kinds of ADF for a specific set of \((i_{type}N, j_{type}N, k_{type}N)\). The values in the first ADF column are normalized numbers \(\geq 0.0\), whose integral w.r.t. the ordinate is 1, i.e. the first ADF is a normalized probability distribution. The values in the second ADF column are also numbers \(\geq 0.0\). They are the cumulative density distribution of angles per atom. By definition, this ADF is monotonically increasing from zero to a maximum value equal to the average total number of angles per atom satisfying the ADF criteria.

19.2.5 Restrictions

The ADF is not computed for neighbors outside the force cutoff, since processors (in parallel) don’t know about atom coordinates for atoms further away than that distance. If you want an ADF for larger distances, you can use the rerun command to post-process a dump file and set the cutoff for the potential to be longer in the rerun script. Note that in the rerun context, the force cutoff is arbitrary, since you are not running dynamics and thus are not changing your model.

19.2.6 Related commands

\texttt{compute rdf, fix ave/time, compute\_modify}

19.2.7 Default

The keyword default is ordinate = degree.

19.3 compute angle command

19.3.1 Syntax

\texttt{compute ID group-ID angle}

- ID, group-ID are documented in \texttt{compute} command
- angle = style name of this compute command

19.3.2 Examples

compute 1 all angle

19.3.3 Description

Define a computation that extracts the angle energy calculated by each of the angle sub-styles used in the “angle_style hybrid” angle_hybrid.html command. These values are made accessible for output or further processing by other commands. The group specified for this command is ignored.

This compute is useful when using angle_style hybrid if you want to know the portion of the total energy contributed by one or more of the hybrid sub-styles.

19.3.4 Output info

This compute calculates a global vector of length N where N is the number of sub_styles defined by the angle_style hybrid command, which can be accessed by indices 1-N. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The vector values are “extensive” and will be in energy units.

19.4 compute angle/local command

19.4.1 Syntax

compute ID group-ID angle/local value1 value2 ... keyword args ...

- ID, group-ID are documented in compute command
- angle/local = style name of this compute command
- one or more values may be appended
- value = theta or eng or v_name
theta = tabulate angles
eng = tabulate angle energies
v_name = equal-style variable with name (see below)

- zero or more keyword/args pairs may be appended
- keyword = set

  set args = theta name
  theta = only currently allowed arg
  name = name of variable to set with theta

### 19.4.2 Examples

```
compute 1 all angle/local theta
compute 1 all angle/local eng theta
compute 1 all angle/local theta v_cos set theta t
```

### 19.4.3 Description

Define a computation that calculates properties of individual angle interactions. The number of datums generated, aggregated across all processors, equals the number of angles in the system, modified by the group parameter as explained below.

The value `theta` is the angle for the 3 atoms in the interaction.

The value `eng` is the interaction energy for the angle.

The value `v_name` can be used together with the `set` keyword to compute a user-specified function of the angle `theta`. The `name` specified for the `v_name` value is the name of an equal-style variable which should evaluate a formula based on a variable which will store the angle `theta`. This other variable must be an internal-style variable defined in the input script; its initial numeric value can be anything. It must be an internal-style variable, because this command resets its value directly. The `set` keyword is used to identify the name of this other variable associated with `theta`.

Note that the value of `theta` for each angle which stored in the internal variable is in radians, not degrees.

As an example, these commands can be added to the bench/in.rhodo script to compute the cosine and cosine^2 of every angle in the system and output the statistics in various ways:

```
variable t internal 0.0
variable cos equal cos(v_t)
variable cossq equal cos(v_t)*cos(v_t)

compute 1 all property/local aatoml aatom2 aatom3 atype
compute 2 all angle/local eng theta v_cos v_cossq set theta t
dump 1 all local 100 tmp.dump c_1[*] c_2[*]

compute 3 all reduce ave c_2[*]
thermo_style custom step temp press c_3[*]
fix 10 all ave/histo 10 10 100 -1 1 20 c_2[3] mode vector file tmp.histo
```

The `dump local` command will output the energy, angle, cosine(angle), cosine^2(angle) for every angle in the system. The `thermo_style` command will print the average of those quantities via the `compute reduce` command with thermo output. And the `fix ave/histo` command will histogram the cosine(angle) values and write them to a file.
The local data stored by this command is generated by looping over all the atoms owned on a processor and their angles. An angle will only be included if all 3 atoms in the angle are in the specified compute group. Any angles that have been broken (see the angle_style command) by setting their angle type to 0 are not included. Angles that have been turned off (see the fix shake or delete_bonds commands) by setting their angle type negative are written into the file, but their energy will be 0.0.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, angle output from the compute property/local command can be combined with data from this command and output by the dump local command in a consistent way.

Here is an example of how to do this:

```plaintext
compute 1 all property/local atype aatom1 aatom2 aatom3
compute 2 all angle/local theta eng
```

19.4.4 Output info

This compute calculates a local vector or local array depending on the number of values. The length of the vector or number of rows in the array is the number of angles. If a single value is specified, a local vector is produced. If two or more values are specified, a local array is produced where the number of columns = the number of values. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The output for theta will be in degrees. The output for eng will be in energy units.

19.5 compute angmom/chunk command

19.5.1 Syntax

```plaintext
compute ID group-ID angmom/chunk chunkID
```

- ID, group-ID are documented in compute command
- angmom/chunk = style name of this compute command
- chunkID = ID of compute chunk/atom command
19.5.2 Examples

compute 1 fluid angmom/chunk molchunk

19.5.3 Description

Define a computation that calculates the angular momentum of multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and Howto chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the 3 components of the angular momentum vector for each chunk, due to the velocity/momentum of the individual atoms in the chunk around the center-of-mass of the chunk. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The compute chunk/atom command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

Note: The coordinates of an atom contribute to the chunk’s angular momentum in “unwrapped” form, by using the image flags associated with each atom. See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the set image command.

The simplest way to output the results of the compute angmom/chunk calculation to a file is to use the fix ave/time command, for example:

compute ccl all chunk/atom molecule
compute myChunk all angmom/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector

19.5.4 Output info

This compute calculates a global array where the number of rows = the number of chunks Nchunk as calculated by the specified compute chunk/atom command. The number of columns = 3 for the 3 xyz components of the angular momentum for each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in mass-velocity-distance units.

19.6 compute basal/atom command

19.6.1 Syntax

```
compute ID group-ID basal/atom
```

- ID, group-ID are documented in *compute* command
- basal/atom = style name of this compute command

19.6.2 Examples

```
compute 1 all basal/atom
```

19.6.3 Description

Defines a computation that calculates the hexagonal close-packed “c” lattice vector for each atom in the group. It does this by calculating the normal unit vector to the basal plane for each atom. The results enable efficient identification and characterization of twins and grains in hexagonal close-packed structures.

The output of the compute is thus the 3 components of a unit vector associated with each atom. The components are set to 0.0 for atoms not in the group.

Details of the calculation are given in *(Barrett).*

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each of which computes this quantity.

An example input script that uses this compute is provided in examples/USER/misc/basal.
19.6.4 Output info

This compute calculates a per-atom array with 3 columns, which can be accessed by indices 1-3 by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector values are unitless since the 3 columns represent components of a unit vector.

19.6.5 Restrictions

This compute is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The output of this compute will be meaningless unless the atoms are on (or near) hcp lattice sites, since the calculation assumes a well-defined basal plane.

19.7 compute body/local command

19.7.1 Syntax

compute ID group-ID body/local input1 input2 ...

- ID, group-ID are documented in compute command
- body/local = style name of this compute command
- one or more keywords may be appended
- keyword = id or type or integer

id = atom ID of the body particle
type = atom type of the body particle
integer = 1,2,3,etc = index of fields defined by body style
19.7.2 Examples

```
compute 1 all body/local type 1 2 3
compute 1 all body/local 3 6
```

19.7.3 Description

Define a computation that calculates properties of individual body sub-particles. The number of datums generated, aggregated across all processors, equals the number of body sub-particles plus the number of non-body particles in the system, modified by the group parameter as explained below. See the Howto body doc page for more details on using body particles.

The local data stored by this command is generated by looping over all the atoms. An atom will only be included if it is in the group. If the atom is a body particle, then its N sub-particles will be looped over, and it will contribute N datums to the count of datums. If it is not a body particle, it will contribute 1 datum.

For both body particles and non-body particles, the id keyword will store the ID of the particle.

For both body particles and non-body particles, the type keyword will store the type of the particle.

The integer keywords mean different things for body and non-body particles. If the atom is not a body particle, only its x, y, z coordinates can be referenced, using the integer keywords 1,2,3. Note that this means that if you want to access more fields than this for body particles, then you cannot include non-body particles in the group.

For a body particle, the integer keywords refer to fields calculated by the body style for each sub-particle. The body style, as specified by the atom_style body, determines how many fields exist and what they are. See the Howto_body doc page for details of the different styles.

Here is an example of how to output body information using the dump local command with this compute. If fields 1,2,3 for the body sub-particles are x,y,z coordinates, then the dump file will be formatted similar to the output of a dump atom or custom command.

```
compute 1 all body/local type 1 2 3
```

19.7.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of datums as described above. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The units for output values depend on the body style.

19.8.1 Syntax

\[
\text{compute ID group-ID bond}
\]

- ID, group-ID are documented in compute command
- bond = style name of this compute command

19.8.2 Examples

\[
\text{compute 1 all bond}
\]

19.8.3 Description

Define a computation that extracts the bond energy calculated by each of the bond sub-styles used in the bond_style hybrid command. These values are made accessible for output or further processing by other commands. The group specified for this command is ignored.

This compute is useful when using bond_style hybrid if you want to know the portion of the total energy contributed by one or more of the hybrid sub-styles.

19.8.4 Output info

This compute calculates a global vector of length N where N is the number of sub_styles defined by the bond_style hybrid command, which can be accessed by indices 1-N. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The vector values are “extensive” and will be in energy units.

- one or more values may be appended
  - value = dist or engpot or force or fx or fy or fz or engvib or engrot or engtrans or omega or velvib or v_name

dist = bond distance
genpot = bond potential energy
force = bond force

fx, fy, fz = components of bond force
genvib = bond kinetic energy of vibration
genrot = bond kinetic energy of rotation
engtrans = bond kinetic energy of translation
omega = magnitude of bond angular velocity
velvib = vibrational velocity along the bond length
v_name = equal-style variable with name (see below)

- zero or more keyword/args pairs may be appended
- keyword = set

set args = dist name
  - dist = only currently allowed arg
  - name = name of variable to set with distance (dist)
19.9.2 Examples

```plaintext
compute 1 all bond/local engpot
calculate 1 all bond/local dist engpot force
calculate 1 all bond/local dist fx fy fz
calculate 1 all angle/local dist v_distsq set dist d
```

19.9.3 Description

Define a computation that calculates properties of individual bond interactions. The number of datums generated, aggregated across all processors, equals the number of bonds in the system, modified by the group parameter as explained below.

All these properties are computed for the pair of atoms in a bond, whether the 2 atoms represent a simple diatomic molecule, or are part of some larger molecule.

The value dist is the current length of the bond.

The value engpot is the potential energy for the bond, based on the current separation of the pair of atoms in the bond.

The value force is the magnitude of the force acting between the pair of atoms in the bond.

The values fx, fy, and fz are the xyz components of force between the pair of atoms in the bond.

The remaining properties are all computed for motion of the two atoms relative to the center of mass (COM) velocity of the 2 atoms in the bond.

The value engvib is the vibrational kinetic energy of the two atoms in the bond, which is simply 1/2 m1 v1^2 + 1/2 m2 v2^2, where v1 and v2 are the magnitude of the velocity of the 2 atoms along the bond direction, after the COM velocity has been subtracted from each.

The value engrot is the rotational kinetic energy of the two atoms in the bond, which is simply 1/2 m1 v1^2 + 1/2 m2 v2^2, where v1 and v2 are the magnitude of the velocity of the 2 atoms perpendicular to the bond direction, after the COM velocity has been subtracted from each.

The value engtrans is the translational kinetic energy associated with the motion of the COM of the system itself, namely 1/2 (m1+m2) Vcm^2 where Vcm = magnitude of the velocity of the COM.

Note that these 3 kinetic energy terms are simply a partitioning of the summed kinetic energy of the 2 atoms themselves. I.e. total KE = 1/2 m1 v1^2 + 1/2 m2 v2^2 = engvib + engrot + engtrans, where v1,v2 are the magnitude of the velocities of the 2 atoms, without any adjustment for the COM velocity.

The value omega is the magnitude of the angular velocity of the two atoms around their COM position.

The value velvib is the magnitude of the relative velocity of the two atoms in the bond towards each other. A negative value means the 2 atoms are moving toward each other; a positive value means they are moving apart.

The value v_name can be used together with the set keyword to compute a user-specified function of the bond distance. The name specified for the v_name value is the name of an equal-style variable which should evaluate a formula based on a variable which will store the bond distance. This other variable must be an internal-style variable defined in the input script; its initial numeric value can be anything. It must be an internal-style variable, because this command resets its value directly. The set keyword is used to identify the name of this other variable associated with theta.

As an example, these commands can be added to the bench/in.rhodo script to compute the distance^2 of every bond in the system and output the statistics in various ways:
variable d internal 0.0
variable dsq equal v_d*v_d

compute 1 all property/local batom1 batom2 btype
compute 2 all bond/local engpot dist v_dsq set dist d
dump 1 all local 100 tmp.dump c_1[*] c_2[*]

compute 3 all reduce ave c_2[*]
thermo_style custom step temp press c_3[*]

fix 10 all ave/histo 10 10 1000 0 6 20 c_2[3] mode vector file tmp.histo

The dump local command will output the energy, distance, distance^2 for every bond in the system. The thermo_style command will print the average of those quantities via the compute reduce command with thermo output. And the fix ave/histo command will histogram the distance^2 values and write them to a file.

The local data stored by this command is generated by looping over all the atoms owned on a processor and their bonds. A bond will only be included if both atoms in the bond are in the specified compute group. Any bonds that have been broken (see the bond_style command) by setting their bond type to 0 are not included. Bonds that have been turned off (see the fix shake or delete_bonds commands) by setting their bond type negative are written into the file, but their energy will be 0.0.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, bond output from the compute property/local command can be combined with data from this command and output by the dump local command in a consistent way.

Here is an example of how to do this:

calculate 1 all property/local btype batom1 batom2
calculate 2 all bond/local dist engpot
dump 1 all local 1000 tmp.dump index c_1[*] c_2[*]

### 19.9.4 Output info

This compute calculates a local vector or local array depending on the number of values. The length of the vector or number of rows in the array is the number of bonds. If a single value is specified, a local vector is produced. If two or more values are specified, a local array is produced where the number of columns = the number of values. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The output for dist will be in distance units. The output for velvib will be in velocity units. The output for omega will be in velocity/distance units. The output for engtrans, engvib, engrot, and engpot will be in energy units. The output for force will be in force units.

19.10 compute centro/atom command

19.10.1 Syntax

```
compute ID group-ID centro/atom lattice keyword value ...
```

- ID, group-ID are documented in compute command centro/atom = style name of this compute command lattice
  = fcc or bcc or N = # of neighbors per atom to include
- zero or more keyword/value pairs may be appended
- keyword = axes
  axes value = no or yes
  no = do not calculate 3 symmetry axes
  yes = calculate 3 symmetry axes

19.10.2 Examples

```
compute 1 all centro/atom fcc
compute 1 all centro/atom 8
```

19.10.3 Description

Define a computation that calculates the centro-symmetry parameter for each atom in the group, for either FCC or BCC lattices, depending on the choice of the lattice argument. In solid-state systems the centro-symmetry parameter is a useful measure of the local lattice disorder around an atom and can be used to characterize whether the atom is part of a perfect lattice, a local defect (e.g. a dislocation or stacking fault), or at a surface.

The value of the centro-symmetry parameter will be 0.0 for atoms not in the specified compute group.

This parameter is computed using the following formula from (Kelchner)

\[
CS = \sum_{i=1}^{N/2} |\vec{R}_i + \vec{R}_{i+N/2}|^2
\]
where the \( N \) nearest neighbors of each atom are identified and \( \vec{R}_i \) and \( \vec{R}_{i+N/2} \) are vectors from the central atom to a particular pair of nearest neighbors. There are \( N(N-1)/2 \) possible neighbor pairs that can contribute to this formula. The quantity in the sum is computed for each, and the \( N/2 \) smallest are used. This will typically be for pairs of atoms in symmetrically opposite positions with respect to the central atom; hence the \( i + N/2 \) notation.

\( N \) is an input parameter, which should be set to correspond to the number of nearest neighbors in the underlying lattice of atoms. If the keyword \texttt{fcc} or \texttt{bcc} is used, \( N \) is set to 12 and 8 respectively. More generally, \( N \) can be set to a positive, even integer.

For an atom on a lattice site, surrounded by atoms on a perfect lattice, the centro-symmetry parameter will be 0. It will be near 0 for small thermal perturbations of a perfect lattice. If a point defect exists, the symmetry is broken, and the parameter will be a larger positive value. An atom at a surface will have a large positive parameter. If the atom does not have \( N \) neighbors (within the potential cutoff), then its centro-symmetry parameter is set to 0.0.

If the keyword \texttt{axes} has the setting \texttt{yes}, then this compute also estimates three symmetry axes for each atom’s local neighborhood. The first two of these are the vectors joining the two pairs of neighbor atoms with smallest contributions to the centrosymmetry parameter, i.e. the two most symmetric pairs of atoms. The third vector is normal to the first two by the right-hand rule. All three vectors are normalized to unit length. For FCC crystals, the first two vectors will lie along a \(<110>\) direction, while the third vector will lie along either a \(<100>\) or \(<111>\) direction. For HCP crystals, the first two vectors will lie along \(<1000>\) directions, while the third vector will lie along \(<0001>\). This provides a simple way to measure local orientation in HCP structures. In general, the \texttt{axes} keyword can be used to estimate the orientation of symmetry axes in the neighborhood of any atom.

Only atoms within the cutoff of the pairwise neighbor list are considered as possible neighbors. Atoms not in the compute group are included in the \( N \) neighbors used in this calculation.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a centro/atom style.

### 19.10.4 Output info

By default, this compute calculates the centrosymmetry value for each atom as a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the \textit{Howto output} doc page for an overview of LAMMPS output options.

If the \texttt{axes} keyword setting is \texttt{yes}, then a per-atom array is calculated. The first column is the centrosymmetry parameter. The next three columns are the \( x \), \( y \), and \( z \) components of the first symmetry axis, followed by the second, and third symmetry axes in columns 5-7 and 8-10.

The centrosymmetry values are unitless values \( \geq 0.0 \). Their magnitude depends on the lattice style due to the number of contributing neighbor pairs in the summation in the formula above. And it depends on the local defects surrounding the central atom, as described above. For the \texttt{axes yes} case, the vector components are also unitless, since they represent spatial directions.

Here are typical centro-symmetry values, from a nanoindentation simulation into gold (FCC). These were provided by Jon Zimmerman (Sandia):

```
Bulk lattice = 0
Dislocation core ~ 1.0 (0.5 to 1.25)
Stacking faults ~ 5.0 (4.0 to 6.0)
Free surface ~ 23.0
```

These values are *not* normalized by the square of the lattice parameter. If they were, normalized values would be:

```
Bulk lattice = 0
Dislocation core ~ 0.06 (0.03 to 0.075)
```

(continues on next page)
Stacking faults ~ 0.3 (0.24 to 0.36)
Free surface ~ 1.38

For BCC materials, the values for dislocation cores and free surfaces would be somewhat different, due to their being only 8 neighbors instead of 12.

19.11.3 Description

Define a computation that calculates an integer chunk ID from 1 to Nchunk for each atom in the group. Values of chunk IDs are determined by the style of chunk, which can be based on atom type or molecule ID or spatial binning or a per-atom property or value calculated by another compute, fix, or atom-style variable. Per-atom chunk IDs can be used by other computes with “chunk” in their style name, such as compute com/chunk or compute msd/chunk. Or they can be used by the fix ave/chunk command to sum and time average a variety of per-atom properties over the atoms in each chunk. Or they can simply be accessed by any command that uses per-atom values from a compute as input, as discussed on the Howto output doc page.

See the Howto chunk doc page for an overview of how this compute can be used with a variety of other commands to tabulate properties of a simulation. The page gives several examples of input script commands that can be used to calculate interesting properties.

Conceptually it is important to realize that this compute does two simple things. First, it sets the value of Nchunk = the number of chunks, which can be a constant value or change over time. Second, it assigns each atom to a chunk via a chunk ID. Chunk IDs range from 1 to Nchunk inclusive; some chunks may have no atoms assigned to them. Atoms that do not belong to any chunk are assigned a value of 0. Note that the two operations are not always performed together. For example, spatial bins can be setup once (which sets Nchunk), and atoms assigned to those bins many times thereafter (setting their chunk IDs).

All other commands in LAMMPS that use chunk IDs assume there are Nchunk number of chunks, and that every atom is assigned to one of those chunks, or not assigned to any chunk.

There are many options for specifying for how and when Nchunk is calculated, and how and when chunk IDs are assigned to atoms. The details depend on the chunk style and its args, as well as optional keyword settings. They can also depend on whether a fix ave/chunk command is using this compute, since that command requires Nchunk to remain static across windows of timesteps it specifies, while it accumulates per-chunk averages.

The details are described below.

The different chunk styles operate as follows. For each style, how it calculates Nchunk and assigns chunk IDs to atoms is explained. Note that using the optional keywords can change both of those actions, as described further below where the keywords are discussed.

The binning styles perform a spatial binning of atoms, and assign an atom the chunk ID corresponding to the bin number it is in. Nchunk is set to the number of bins, which can change if the simulation box size changes. This also depends on the setting of the units keyword; e.g. for reduced units the number of chunks may not change even if the box size does.

The bin/1d, bin/2d, and bin/3d styles define bins as 1d layers (slabs), 2d pencils, or 3d boxes. The dim, origin, and delta settings are specified 1, 2, or 3 times. For 2d or 3d bins, there is no restriction on specifying dim = x before dim = y or z, or dim = y before dim = z. Bins in a particular dim have a bin size in that dimension given by delta. In each dimension, bins are defined relative to a specified origin, which may be the lower/upper edge of the simulation box (in
that dimension), or its center point, or a specified coordinate value. Starting at the origin, sufficient bins are created in both directions to completely span the simulation box or the bounds specified by the optional bounds keyword.

For triclinic simulation boxes, the bins are layers, pencils, or boxes aligned with the xyz coordinate axes. For triclinic (non-orthogonal) simulation boxes, the bin faces are parallel to the tilted faces of the simulation box. See the How to triclinic doc page for a discussion of the geometry of triclinic boxes in LAMMPS. As described there, a tilted simulation box has edge vectors a,b,c. In that nomenclature, bins in the x dimension have faces with normals in the “b” cross “c” direction. Bins in y have faces normal to the “a” cross “c” direction. And bins in z have faces normal to the “a” cross “b” direction. Note that in order to define the size and position of these bins in an unambiguous fashion, the units option must be set to reduced when using a triclinic simulation box, as noted below.

The meaning of origin and delta for triclinic boxes is as follows. Consider a triclinic box with bins that are 1d layers or slabs in the x dimension. No matter how the box is tilted, an origin of 0.0 means start layers at the lower “b” cross “c” plane of the simulation box and an origin of 1.0 means to start layers at the upper “b” cross “c” face of the box. A delta value of 0.1 in reduced units means there will be 10 layers from 0.0 to 1.0, regardless of the current size or shape of the simulation box.

The bin/sphere style defines a set of spherical shell bins around the origin (xorig,yorig,zorig), using nsbin bins with radii equally spaced between srmin and srmax. This is effectively a 1d vector of bins. For example, if srmin = 1.0 and srmax = 10.0 and nsbin = 9, then the first bin spans 1.0 < r < 2.0, and the last bin spans 9.0 < r 10.0. The geometry of the bins is the same whether the simulation box is orthogonal or triclinic; i.e. the spherical shells are not tilted or scaled differently in different dimensions to transform them into ellipsoidal shells.

The bin/cylinder style defines bins for a cylinder oriented along the axis dim with the axis coordinates in the other two radial dimensions at (c1,c2). For dim = x, c1/c2 = y/z; for dim = y, c1/c2 = x/z; for dim = z, c1/c2 = x/y. This is effectively a 2d array of bins. The first bin is aligned with the cylinder axis, the second dimension is radially outward from the cylinder axis. The bin size and positions along the cylinder axis are specified by the origin and delta values, the same as for the bin/1d, bin/2d, and bin/3d styles. There are ncbin concentric circle bins in the radial direction from the cylinder axis with radii equally spaced between crmin and crmax. For example, if crmin = 1.0 and crmax = 10.0 and ncbin = 9, then the first bin spans 1.0 < r < 2.0, and the last bin spans 9.0 < r 10.0. The geometry of the bins in the radial dimensions is the same whether the simulation box is orthogonal or triclinic; i.e. the concentric circles are not tilted or scaled differently in the two different dimensions to transform them into ellipses.

The created bins (and hence the chunk IDs) are numbered consecutively from 1 to the number of bins = Nchunk. For bin2d and bin3d, the numbering varies most rapidly in the first dimension (which could be x, y, or z), then rapidly in the second dimension, and most slowly in the third dimension. For bin/sphere, the bin with smallest radii is chunk 1 and the bin with largest radii is chunk Nchunk = ncbin. For bin/cylinder, the numbering varies most rapidly in the dimension along the cylinder axis and most slowly in the radial direction.

Each time this compute is invoked, each atom is mapped to a bin based on its current position. Note that between reneighboring timesteps, atoms can move outside the current simulation box. If the box is periodic (in that dimension) the atom is remapping into the periodic box for purposes of binning. If the box is not periodic, the atom may have moved outside the bounds of all bins. If an atom is not inside any bin, the discard keyword is used to determine how a chunk ID is assigned to the atom.

The type style uses the atom type as the chunk ID. Nchunk is set to the number of atom types defined for the simulation, e.g. via the create_box or read_data commands.

The molecule style uses the molecule ID of each atom as its chunk ID. Nchunk is set to the largest chunk ID. Note that this excludes molecule IDs for atoms which are not in the specified group or optional region.

There is no requirement that all atoms in a particular molecule are assigned the same chunk ID (zero or non-zero), though you probably want that to be the case, if you wish to compute a per-molecule property. LAMMPS will issue a warning if that is not the case, but only the first time that Nchunk is calculated.
Note that atoms with a molecule ID = 0, which may be non-molecular solvent atoms, have an out-of-range chunk ID. These atoms are discarded (not assigned to any chunk) or assigned to \( N_{chunk} \), depending on the value of the \textit{discard} keyword.

The \textit{compute}/\textit{fix}/\textit{variable} styles set the chunk ID of each atom based on a quantity calculated and stored by a compute, fix, or variable. In each case, it must be a per-atom quantity. In each case the referenced floating point values are converted to an integer chunk ID as follows. The floating point value is truncated (rounded down) to an integer value. If the integer value is \( \leq 0 \), then a chunk ID of 0 is assigned to the atom. If the integer value is \( > 0 \), it becomes the chunk ID to the atom. \( N_{chunk} \) is set to the largest chunk ID. Note that this excludes atoms which are not in the specified group or optional region.

If the style begins with \textit{c}_\textit{\_}, a compute ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the \textit{Ith} column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and \textit{add them to LAMMPS}.

If the style begins with \textit{f}_\textit{\_}, a fix ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the \textit{Ith} column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with the timestep on which this compute accesses the fix, else an error results. Users can also write code for their own fix styles and \textit{add them to LAMMPS}.

If a value begins with \textit{v}_\textit{\_}, a variable name for an \textit{atom} or \textit{atomfile} style \textit{variable} must follow which has been previously defined in the input script. Variables of style \textit{atom} can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to treat as a chunk ID.

Normally, \( N_{chunk} \) = the number of chunks, is re-calculated every time this fix is invoked, though the value may or may not change. As explained below, the \textit{nchunk} keyword can be set to \textit{once} which means \( N_{chunk} \) will never change.

If a \textit{fix ave/chunk} command uses this compute, it can also turn off the re-calculation of \( N_{chunk} \) for one or more windows of timesteps. The extent of the windows, during which \( N_{chunk} \) is held constant, are determined by the \textit{Nevery}, \textit{Nrepeat}, \textit{Nfreq} values and the \textit{ave} keyword setting that are used by the \textit{fix ave/chunk} command.

Specifically, if \textit{ave} = \textit{one}, then for each span of \textit{Nfreq} timesteps, \( N_{chunk} \) is held constant between the first timestep when averaging is done (within the \textit{Nfreq}-length window), and the last timestep when averaging is done (multiple of \textit{Nfreq}). If \textit{ave} = \textit{running} or \textit{window}, then \( N_{chunk} \) is held constant forever, starting on the first timestep when the \textit{fix ave/chunk} command invokes this compute.

Note that multiple \textit{fix ave/chunk} commands can use the same compute chunk/atom compute. However, the time windows they induce for holding \( N_{chunk} \) constant must be identical, else an error will be generated.

The various optional keywords operate as follows. Note that some of them function differently or are ignored by different chunk styles. Some of them also have different default values, depending on the chunk style, as listed below.

The \textit{region} keyword applies to all chunk styles. If used, an atom must be in both the specified group and the specified geometric \textit{region} to be assigned to a chunk.

The \textit{nchunk} keyword applies to all chunk styles. It specifies how often \( N_{chunk} \) is recalculated, which in turn can affect the chunk IDs assigned to individual atoms.

If \textit{nchunk} is set to \textit{once}, then \( N_{chunk} \) is only calculated once, the first time this compute is invoked. If \textit{nchunk} is set to \textit{every}, then \( N_{chunk} \) is re-calculated every time the compute is invoked. Note that, as described above, the use of this compute by the \textit{fix ave/chunk} command can override the \textit{every} setting.
The default values for \texttt{nchunk} are listed below and depend on the chunk style and other system and keyword settings. They attempt to represent typical use cases for the various chunk styles. The \texttt{nchunk} value can always be set explicitly if desired.

The \texttt{limit} keyword can be used to limit the calculated value of \texttt{Nchunk} = the number of chunks. The limit is applied each time \texttt{Nchunk} is calculated, which also limits the chunk IDs assigned to any atom. The \texttt{limit} keyword is used by all chunk styles except the \texttt{binning} styles, which ignore it. This is because the number of bins can be tailored using the \texttt{bound} keyword (described below) which effectively limits the size of \texttt{Nchunk}.

If \texttt{limit} is set to \texttt{Nc} = 0, then no limit is imposed on \texttt{Nchunk}, though the \texttt{compress} keyword can still be used to reduce \texttt{Nchunk}, as described below.

If \texttt{Nc} > 0, then the effect of the \texttt{limit} keyword depends on whether the \texttt{compress} keyword is also used with a setting of \texttt{yes}, and whether the \texttt{compress} keyword is specified before the \texttt{limit} keyword or after.

In all cases, \texttt{Nchunk} is first calculated in the usual way for each chunk style, as described above.

First, here is what occurs if \texttt{compress \texttt{yes}} is not set. If \texttt{limit} is set to \texttt{Nc \texttt{max}}, then \texttt{Nchunk} is reset to the smaller of \texttt{Nchunk} and \texttt{Nc}. If \texttt{limit} is set to \texttt{Nc \texttt{exact}}, then \texttt{Nchunk} is reset to \texttt{Nc}, whether the original \texttt{Nchunk} was larger or smaller than \texttt{Nc}. If \texttt{Nchunk} shrank due to the \texttt{limit} setting, then atom chunk IDs > \texttt{Nchunk} will be reset to 0 or \texttt{Nchunk}, depending on the setting of the \texttt{discard} keyword. If \texttt{Nchunk} grew, there will simply be some chunks with no atoms assigned to them.

If \texttt{compress \texttt{yes}} is set, and the \texttt{compress} keyword comes before the \texttt{limit} keyword, the compression operation is performed first, as described below, which resets \texttt{Nchunk}. The \texttt{limit} keyword is then applied to the new \texttt{Nchunk} value, exactly as described in the preceding paragraph. Note that in this case, all atoms will end up with chunk IDs \(< \texttt{Nc}\), but their original values (e.g. molecule ID or compute/fix/variable) may have been \(> \texttt{Nc}\), because of the compression operation.

If \texttt{compress \texttt{yes}} is set, and the \texttt{compress} keyword comes after the \texttt{limit} keyword, then the \texttt{limit} value of \texttt{Nc} is applied first to the uncompressed value of \texttt{Nchunk}, but only if \texttt{Nc} < \texttt{Nchunk} (whether \texttt{Nc \texttt{max}} or \texttt{Nc \texttt{exact}} is used). This effectively means all atoms with chunk IDs > \texttt{Nc} have their chunk IDs reset to 0 or \texttt{Nc}, depending on the setting of the \texttt{discard} keyword. The compression operation is then performed, which may shrink \texttt{Nchunk} further. If the new \texttt{Nchunk} < \texttt{Nc} and \texttt{limit} = \texttt{Nc \texttt{exact}} is specified, then \texttt{Nchunk} is reset to \texttt{Nc}, which results in extra chunks with no atoms assigned to them. Note that in this case, all atoms will end up with chunk IDs \(< \texttt{Nc}\), and their original values (e.g. molecule ID or compute/fix/variable value) will also have been \(< \texttt{Nc}\).

The \texttt{ids} keyword applies to all chunk styles. If the setting is \texttt{once} then the chunk IDs assigned to atoms the first time this compute is invoked will be permanent, and never be re-computed.

If the setting is \texttt{nfreq} and if a \texttt{fix \texttt{ave/chunk}} command is using this compute, then in each of the \texttt{Nchunk} = constant time windows (discussed above), the chunk ID’s assigned to atoms on the first step of the time window will persist until the end of the time window.

If the setting is \texttt{every}, which is the default, then chunk IDs are re-calculated on any timestep this compute is invoked.

\textbf{Note:} If you want the persistent chunk-IDs calculated by this compute to be continuous when running from a \texttt{restart file}, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with chunk IDs from the restart file.

The \texttt{compress} keyword applies to all chunk styles and affects how \texttt{Nchunk} is calculated, which in turn affects the chunk IDs assigned to each atom. It is useful for converting a “sparse” set of chunk IDs (with many IDs that have no atoms assigned to them), into a “dense” set of IDs, where every chunk has one or more atoms assigned to it.
Two possible use cases are as follows. If a large simulation box is mostly empty space, then the binning style may produce many bins with no atoms. If compress is set to yes, only bins with atoms will be contribute to Nchunk. Likewise, the molecule or compute/fix/variable styles may produce large Nchunk values. For example, the compute cluster/atom command assigns every atom an atom ID for one of the atoms it is clustered with. For a million-atom system with 5 clusters, there would only be 5 unique chunk IDs, but the largest chunk ID might be 1 million, resulting in Nchunk = 1 million. If compress is set to yes, Nchunk will be reset to 5.

If compress is set to no, which is the default, no compression is done. If it is set to yes, all chunk IDs with no atoms are removed from the list of chunk IDs, and the list is sorted. The remaining chunk IDs are renumbered from 1 to Nchunk where Nchunk is the new length of the list. The chunk IDs assigned to each atom reflect the new renumbering from 1 to Nchunk.

The original chunk IDs (before renumbering) can be accessed by the compute property/chunk command and its id keyword, or by the fix ave/chunk command which outputs the original IDs as one of the columns in its global output array. For example, using the “compute cluster/atom” command discussed above, the original 5 unique chunk IDs might be atom IDs (27,4982,58374,857838,1000000). After compression, these will be renumbered to (1,2,3,4,5). The original values (27,...,1000000) can be output to a file by the fix ave/chunk command, or by using the fix ave/time command in conjunction with the compute property/chunk command.

**Note:** The compression operation requires global communication across all processors to share their chunk ID values. It can require large memory on every processor to store them, even after they are compressed, if there are a large number of unique chunk IDs with atoms assigned to them. It uses a STL map to find unique chunk IDs and store them in sorted order. Each time an atom is assigned a compressed chunk ID, it must access the STL map. All of this means that compression can be expensive, both in memory and CPU time. The use of the limit keyword in conjunction with the compress keyword can affect these costs, depending on which keyword is used first. So use this option with care.

The discard keyword applies to all chunk styles. It affects what chunk IDs are assigned to atoms that do not match one of the valid chunk IDs from 1 to Nchunk. Note that it does not apply to atoms that are not in the specified group or optionally specified region. Those atoms are always assigned a chunk ID = 0.

If the calculated chunk ID for an atom is not within the range 1 to Nchunk then it is a “discard” atom. Note that Nchunk may have been shrunk by the limit keyword. Or the compress keyword may have eliminated chunk IDs that were valid before the compression took place, and are now not in the compressed list. Also note that for the molecule chunk style, if new molecules are added to the system, their chunk IDs may exceed a previously calculated Nchunk. Likewise, evaluation of a compute/fix/variable on a later timestep may return chunk IDs that are invalid for the previously calculated Nchunk.

All the chunk styles except the binning styles, must use discard set to either yes or no. If discard is set to yes, which is the default, then every “discard” atom has its chunk ID set to 0. If discard is set to no, every “discard” atom has its chunk ID set to Nchunk. I.e. it becomes part of the last chunk.

The binning styles use the discard keyword to decide whether to discard atoms outside the spatial domain covered by bins, or to assign them to the bin they are nearest to.

For the bin/1d, bin/2d, bin/3d styles the details are as follows. If discard is set to yes, an out-of-domain atom will have its chunk ID set to 0. If discard is set to no, the atom will have its chunk ID set to the first or last bin in that dimension. If discard is set to mixed, which is the default, it will only have its chunk ID set to the first or last bin if bins extend to the simulation box boundary in that dimension. This is the case if the bound keyword settings are lower and upper, which is the default. If the bound keyword settings are numeric values, then the atom will have its chunk ID set to 0 if it is outside the bounds of any bin. Note that in this case, it is possible that the first or last bin extends beyond the numeric bounds settings, depending on the specified origin. If this is the case, the chunk ID of the atom is only set to 0 if it is outside the first or last bin, not if it is simply outside the numeric bounds setting.

19.11. compute chunk/atom command 1481
For the bin/sphere style the details are as follows. If discard is set to yes, an out-of-domain atom will have its chunk ID set to 0. If discard is set to no or mixed, the atom will have its chunk ID set to the first or last bin, i.e. the innermost or outermost spherical shell. If the distance of the atom from the origin is less than rmin, it will be assigned to the first bin. If the distance of the atom from the origin is greater than rmax, it will be assigned to the last bin.

For the bin/cylinder style the details are as follows. If discard is set to yes, an out-of-domain atom will have its chunk ID set to 0. If discard is set to no, the atom will have its chunk ID set to the first or last bin in both the radial and axis dimensions. If discard is set to mixed, which is the default, the radial dimension is treated the same as for discard = no. But for the axis dimension, it will only have its chunk ID set to the first or last bin if bins extend to the simulation box boundary in the axis dimension. This is the case if the bound keyword settings are lower and upper, which is the default. If the bound keyword settings are numeric values, then the atom will have its chunk ID set to 0 if it is outside the bounds of any bin. Note that in this case, it is possible that the first or last bin extends beyond the numeric bounds settings, depending on the specified origin. If this is the case, the chunk ID of the atom is only set to 0 if it is outside the first or last bin, not if it is simply outside the numeric bounds setting.

If discard is set to no or mixed, the atom will have its chunk ID set to the first or last bin, i.e. the innermost or outermost spherical shell. If the distance of the atom from the origin is less than rmin, it will be assigned to the first bin. If the distance of the atom from the origin is greater than rmax, it will be assigned to the last bin.

The bound keyword only applies to the bin/1d, bin/2d, bin/3d styles and to the axis dimension of the bin/cylinder style; otherwise it is ignored. It can be used one or more times to limit the extent of bin coverage in a specified dimension, i.e. to only bin a portion of the box. If the lo setting is lower or the hi setting is upper, the bin extent in that direction extends to the box boundary. If a numeric value is used for lo and/or hi, then the bin extent in the lo or hi direction extends only to that value, which is assumed to be inside (or at least near) the simulation box boundaries, though LAMMPS does not check for this. Note that using the bound keyword typically reduces the total number of bins and thus the number of chunks Nchunk.

The pbc keyword only applies to the bin/sphere and bin/cylinder styles. If set to yes, the distance an atom is from the sphere origin or cylinder axis is calculated in a minimum image sense with respect to periodic dimensions, when determining which bin the atom is in. I.e. if x is a periodic dimension and the distance between the atom and the sphere center in the x dimension is greater than 0.5 * simulation box length in x, then a box length is subtracted to give a distance < 0.5 * simulation box length. This allows the sphere or cylinder center to be near a box edge, and atoms on the other side of the periodic box will still be close to the center point/axis. Note that with a setting of yes, the outer sphere or cylinder radius must also be <= 0.5 * simulation box length in any periodic dimension except for the cylinder axis dimension, or an error is generated.

The units keyword only applies to the binning styles; otherwise it is ignored. For the bin/1d, bin/2d, bin/3d styles, it determines the meaning of the distance units used for the bin sizes delta and for origin and bounds values if they are coordinate values. For the bin/sphere style it determines the meaning of the distance units used for xorig,yorig,zorig and the radii srmin and srmax. For the bin/cylinder style it determines the meaning of the distance units used for delta,c1,c2 and the radii crmin and crmax.

For orthogonal simulation boxes, any of the 3 options may be used. For non-orthogonal (triclinic) simulation boxes, only the reduced option may be used.

A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacing. A reduced value means normalized unitless values between 0 and 1, which represent the lower and upper faces of the simulation box respectively. Thus an origin value of 0.5 means the center of the box in any dimension. A delta value of 0.1 means 10 bins span the box in that dimension.

Note that for the bin/sphere style, the radii srmin and srmax are scaled by the lattice spacing or reduced value of the x dimension.

Note that for the bin/cylinder style, the radii crmin and crmax are scaled by the lattice spacing or reduced value of the first dimension perpendicular to the cylinder axis. E.g. y for an x-axis cylinder, x for a y-axis cylinder, and z for a z-axis cylinder.
19.11.4 Output info

This compute calculates a per-atom vector (the chunk ID), which can be accessed by any command that uses per-atom values from a compute as input. It also calculates a global scalar (the number of chunks), which can be similarly accessed everywhere outside of a per-atom context. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector values are unitless chunk IDs, ranging from 1 to $N_{chunk}$ (inclusive) for atoms assigned to chunks, and 0 for atoms not belonging to a chunk. The scalar contains the value of $N_{chunk}$.

19.11.5 Restrictions

Even if the $n_{chunk}$ keyword is set to once, the chunk IDs assigned to each atom are not stored in a restart files. This means you cannot expect those assignments to persist in a restarted simulation. Instead you must re-specify this command and assign atoms to chunks when the restarted simulation begins.

19.11.6 Related commands

fix ave/chunk, compute global/atom

19.11.7 Default

The option defaults are as follows:

- region = none
- $n_{chunk}$ = every, if compress is yes, overriding other defaults listed here
- $n_{chunk}$ = once, for type style
- $n_{chunk}$ = once, for mol style if region is none
- $n_{chunk}$ = every, for mol style if region is set
- $n_{chunk}$ = once, for binning style if the simulation box size is static or units = reduced
- $n_{chunk}$ = every, for binning style if the simulation box size is dynamic and units is lattice or box
- $n_{chunk}$ = every, for compute/fix/variable style
- limit = 0
- ids = every
- compress = no
- discard = yes, for all styles except binning
- discard = mixed, for binning styles
- bound = lower and upper in all dimensions
- pbc = no
- units = lattice
19.12 compute chunk/spread/atom command

19.12.1 Syntax

```plaintext
compute ID group-ID chunk/spread/atom chunkID input1 input2 ...
```

- ID, group-ID are documented in `compute` command
- chunk/spread/atom = style name of this compute command
- chunkID = ID of `compute chunk/atom` command
- one or more inputs can be listed
- input = c_ID, c_ID[N], f_ID, f_ID[N]

- c_ID = global vector calculated by a compute with ID
- c_ID[I] = Ith column of global array calculated by a compute with ID, I can include wildcard (see below)
- f_ID = global vector calculated by a fix with ID
- f_ID[I] = Ith column of global array calculated by a fix with ID, I can include wildcard (see below)

19.12.2 Examples

```plaintext
compute 1 all chunk/spread/atom mychunk c_com[*] c_gyration
```

19.12.3 Description

Define a calculation that “spreads” one or more per-chunk values to each atom in the chunk. This can be useful in several scenarios:

- For creating a `dump file` where each atom lists info about the chunk it is in, e.g. for post-processing purposes.
- To access chunk value in `atom-style variables` that need info about the chunk each atom is in.
- To use the `fix ave/chunk` command to spatially average per-chunk values calculated by a per-chunk compute.

Examples are given below.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

For inputs that are computes, they must be a compute that calculates per-chunk values. These are computes whose style names end in “/chunk”.

For inputs that are fixes, they should be a fix that calculates per-chunk values. For example, `fix ave/chunk` or `fix ave/time` (assuming it is time-averaging per-chunk data).

For each atom, this compute accesses its chunk ID from the specified chunkID compute, then accesses the per-chunk value in each input. Those values are copied to this compute to become the output for that atom.

The values generated by this compute will be 0.0 for atoms not in the specified compute group group-ID. They will also be 0.0 if the atom is not in a chunk, as assigned by the chunkID compute. They will also be 0.0 if the current
chunk ID for the atom is out-of-bounds with respect to the number of chunks stored by a particular input compute or fix.

Note: LAMMPS does not check that a compute or fix which calculates per-chunk values uses the same definition of chunks as this compute. It’s up to you to be consistent. Likewise, for a fix input, LAMMPS does not check that it is per-chunk data. It only checks that the fix produces a global vector or array.

Each listed input is operated on independently.

If a bracketed index I is used, it can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of columns in the array, then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 compute chunk/spread/atom commands are equivalent, since the compute com/chunk command creates a per-atom array with 3 columns:

```
compute com all com/chunk mychunk
compute 10 all chunk/spread/atom mychunk c_com[*]
```

Here is an example of writing a dump file the with the center-of-mass (COM) for the chunk each atom is in. The commands below can be added to the bench/in.chain script.

```
compute cmol all chunk/atom molecule
compute com all com/chunk cmol
compute comchunk all chunk/spread/atom cmol c_com[*]
dump 1 all custom 50 tmp.dump id mol type x y z c_comchunk[*]
dump_modify 1 sort id
```

The same per-chunk data for each atom could be used to define per-atom forces for the fix addforce command. In this example the forces act to pull atoms of an extended polymer chain towards its COM in an attractive manner.

```
compute prop all property/atom xu yu zu
variable k equal 0.1
variable fx atom v_k*(c_comchunk[1]-c_prop[1])
variable fy atom v_k*(c_comchunk[2]-c_prop[2])
variable fz atom v_k*(c_comchunk[3]-c_prop[3])
fix 3 all addforce v_fx v_fy v_fz
```

Note that compute property/atom is used to generate unwrapped coordinates for use in the per-atom force calculation, so that the effect of periodic boundaries is accounted for properly.

Over time this applied force could shrink each polymer chain’s radius of gyration in a polymer mixture simulation. Here is output from the bench/in.chain script. Thermo output is shown for 1000 steps, where the last column is the average radius of gyration over all 320 chains in the 32000 atom system:

```
compute gyr all gyration/chunk cmol
variable ave equal ave(c_gyr)
thermo_style custom step etotal press v_ave
0  22.394765  4.6721833  5.128278
```

(continues on next page)
Here is an example for using one set of chunks, defined for molecules, to compute the dipole moment vector for each chunk. E.g. for water molecules. Then spreading those values to each atom in each chunk. Then defining a second set of chunks based on spatial bins. And finally, using the `fix ave/chunk` command to calculate an average dipole moment vector per spatial bin.

```plaintext
compute cmol all chunk/atom molecule
compute dipole all dipole/chunk cmol
compute cspatial all chunk/atom bin/1d z lower 0.1 units reduced
fix ave all ave/chunk 100 10 1000 cspatial c_spread[*]
```

Note that the `fix ave/chunk` command requires per-atom values as input. That is why the compute chunk/spread/atom command is used to assign per-chunk values to each atom in the chunk. If a molecule straddles bin boundaries, each of its atoms contributes in a weighted manner to the average dipole moment of the spatial bin it is in.

**19.12.4 Output info**

This compute calculates a per-atom vector or array, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The output is a per-atom vector if a single input value is specified, otherwise a per-atom array is output. The number of columns in the array is the number of inputs provided. The per-atom values for the vector or each column of the array will be in whatever units the corresponding input value is in.

The vector or array values are “intensive”.

compute ID group-ID fragment/atom keyword value ...
compute ID group-ID aggregate/atom cutoff

- ID, group-ID are documented in compute command
- cluster/atom or fragment/atom or aggregate/atom = style name of this compute command
- cutoff = distance within which to label atoms as part of same cluster (distance units)
- zero or more keyword/value pairs may be appended to fragment/atom
- keyword = single
  
  single value = yes or no to treat single atoms (no bonds) as fragments

19.15.2 Examples

```
compute 1 all cluster/atom 3.5
compute 1 all fragment/atom
compute 1 all fragment/atom single no
compute 1 all aggregate/atom 3.5
```

19.15.3 Description

Define a computation that assigns each atom a cluster, fragment, or aggregate ID. Only atoms in the compute group are clustered and assigned cluster IDs. Atoms not in the compute group are assigned an ID = 0.

A cluster is defined as a set of atoms, each of which is within the cutoff distance from one or more other atoms in the cluster. If an atom has no neighbors within the cutoff distance, then it is a 1-atom cluster.

A fragment is similarly defined as a set of atoms, each of which has a bond to another atom in the fragment. Bonds can be defined initially via the data file or create_bonds commands, or dynamically by fixes which create or break bonds like fix bond/react, fix bond/create, fix bond/swap, or fix bond/break. The cluster ID or fragment ID of every atom in the cluster will be set to the smallest atom ID of any atom in the cluster or fragment, respectively.

19.13. compute cluster/atom command
For the \texttt{fragment/atom} style, the \textit{single} keyword determines whether single atoms (not bonded to another atom) are treated as one-atom fragments or not, based on the \textit{yes} or \textit{no} setting. If the setting is \textit{no} (the default), their fragment IDs are set to 0.

An aggregate is defined by combining the rules for clusters and fragments, i.e. a set of atoms, where each of it is within the cutoff distance from one or more atoms within a fragment that is part of the same cluster. This measure can be used to track molecular assemblies like micelles.

For computes \texttt{cluster/atom} and \texttt{aggregate/atom} a neighbor list needed to compute cluster IDs is constructed each time the compute is invoked. Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple \texttt{cluster/atom} or \texttt{aggregate/atom} style computes.

\textbf{Note:} If you have a bonded system, then the settings of \texttt{special_bonds} command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the \texttt{special_bonds} command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included when computing the clusters. This does not apply when using long-range coulomb (\texttt{coul/long}, \texttt{coul/msm}, \texttt{coul/wolf} or similar. One way to get around this would be to set \texttt{special_bond scaling factors} to very tiny numbers that are not exactly zero (e.g. 1.0e-50). Another workaround is to write a dump file, and use the \texttt{rerun} command to compute the clusters for snapshots in the dump file. The rerun script can use a \texttt{special_bonds} command that includes all pairs in the neighbor list.

\textbf{Note:} For the compute fragment/atom style, each fragment is identified using the current bond topology. This will not account for bonds broken by the \texttt{bond_style quartic} command because it does not perform a full update of the bond topology data structures within LAMMPS.

\section*{19.15.4 Output info}

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the \texttt{Howto output} doc page for an overview of LAMMPS output options.

The per-atom vector values will be an ID > 0, as explained above.

\section*{19.15.5 Restrictions}

19.16 compute cna/atom command

19.16.1 Syntax

```plaintext
compute ID group-ID cna/atom cutoff
```

- ID, group-ID are documented in `compute` command
- cna/atom = style name of this compute command
- cutoff = cutoff distance for nearest neighbors (distance units)

19.16.2 Examples

```plaintext
compute 1 all cna/atom 3.08
```

19.16.3 Description

Define a computation that calculates the CNA (Common Neighbor Analysis) pattern for each atom in the group. In solid-state systems the CNA pattern is a useful measure of the local crystal structure around an atom. The CNA methodology is described in (Faken) and (Tsuzuki).

Currently, there are five kinds of CNA patterns LAMMPS recognizes:

- fcc = 1
- hcp = 2
- bcc = 3
- icosahedral = 4
- unknown = 5

The value of the CNA pattern will be 0 for atoms not in the specified compute group. Note that normally a CNA calculation should only be performed on mono-component systems.

The CNA calculation can be sensitive to the specified cutoff value. You should insure the appropriate nearest neighbors of an atom are found within the cutoff distance for the presumed crystal structure. E.g. 12 nearest neighbor for perfect FCC and HCP crystals, 14 nearest neighbors for perfect BCC crystals. These formulas can be used to obtain a good cutoff distance:

\[
r_{c}^{fcc} = \frac{1}{2} \left( \frac{\sqrt{2}}{2} + 1 \right) a \approx 0.8536 \ a
\]

\[
r_{c}^{bcc} = \frac{1}{2} (\sqrt{2} + 1) a \approx 1.207 \ a
\]

\[
r_{c}^{hcp} = \frac{1}{2} \left( 1 + \sqrt{\frac{4 + 2x^2}{3}} \right) a
\]
where \( a \) is the lattice constant for the crystal structure concerned and in the HCP case, \( x = (c/a) / 1.633 \), where 1.633 is the ideal \( c/a \) for HCP crystals.

Also note that since the CNA calculation in LAMMPS uses the neighbors of an owned atom to find the nearest neighbors of a ghost atom, the following relation should also be satisfied:

\[
    r_c + r_s > 2 \times \text{cutoff}
\]

where \( r_c \) is the cutoff distance of the potential, \( r_s \) is the skin distance as specified by the \textit{neighbor} command, and \textit{cutoff} is the argument used with the \textit{compute cna/atom} command. LAMMPS will issue a warning if this is not the case.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a \textit{cna/atom} style.

### 19.16.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the \textit{Howto output} doc page for an overview of LAMMPS output options.

The per-atom vector values will be a number from 0 to 5, as explained above.

- cutoff = cutoff distance for nearest neighbors (distance units)
19.17.2 Examples

\texttt{compute 1 all cnp/atom 3.08}

19.17.3 Description

Define a computation that calculates the Common Neighborhood Parameter (CNP) for each atom in the group. In solid-state systems the CNP is a useful measure of the local crystal structure around an atom and can be used to characterize whether the atom is part of a perfect lattice, a local defect (e.g. a dislocation or stacking fault), or at a surface.

The value of the CNP parameter will be 0.0 for atoms not in the specified compute group. Note that normally a CNP calculation should only be performed on single component systems.

This parameter is computed using the following formula from (Tsuzuki)

\[ Q_i = \frac{1}{n_i} \sum_{j=1}^{n_i} \sum_{k=1}^{n_{ij}} | \vec{R}_{ik} + \vec{R}_{jk} |^2 \]

where the index \( j \) goes over the \( n_i \) nearest neighbors of atom \( i \), and the index \( k \) goes over the \( n_{ij} \) common nearest neighbors between atom \( i \) and atom \( j \). \( \vec{R}_{ik} \) and \( \vec{R}_{jk} \) are the vectors connecting atom \( k \) to atoms \( i \) and \( j \). The quantity in the double sum is computed for each atom.

The CNP calculation is sensitive to the specified cutoff value. You should ensure that the appropriate nearest neighbors of an atom are found within the cutoff distance for the presumed crystal structure. E.g. 12 nearest neighbor for perfect FCC and HCP crystals, 14 nearest neighbors for perfect BCC crystals. These formulas can be used to obtain a good cutoff distance:

\[ r_{cc}^f = \frac{1}{2} \left( \frac{\sqrt{2}}{2} + 1 \right) a \approx 0.8536 a \]
\[ r_{bc}^f = \frac{1}{2} (\sqrt{2} + 1)a \approx 1.207 a \]
\[ r_{hc}^f = \frac{1}{2} \left( 1 + \sqrt{\frac{4 + 2x^2}{3}} \right) a \]

where \( a \) is the lattice constant for the crystal structure concerned and in the HCP case, \( x = (c/a) / 1.633 \), where 1.633 is the ideal \( c/a \) for HCP crystals.

Also note that since the CNP calculation in LAMMPS uses the neighbors of an owned atom to find the nearest neighbors of a ghost atom, the following relation should also be satisfied:

\[ r_c + r_s > 2 \times \text{cutoff} \]

where \( r_c \) is the cutoff distance of the potential, \( r_s \) is the skin distance as specified by the \texttt{neighbor} command, and cutoff is the argument used with the compute cnp/atom command. LAMMPS will issue a warning if this is not the case.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a \texttt{cnpl/atom} style.
19.17.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector values will be real positive numbers. Some typical CNP values:

```
FCC lattice = 0.0
BCC lattice = 0.0
HCP lattice = 4.4

FCC (111) surface ~ 13.0
FCC (100) surface ~ 26.5
FCC dislocation core ~ 11
```

19.17.5 Restrictions

This compute is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

```

- ID, group-ID are documented in compute command
- com = style name of this compute command
19.18.2 Examples

\texttt{compute 1 all com}

19.18.3 Description

Define a computation that calculates the center-of-mass of the group of atoms, including all effects due to atoms passing through periodic boundaries.

A vector of three quantities is calculated by this compute, which are the x,y,z coordinates of the center of mass.

\textbf{Note:} The coordinates of an atom contribute to the center-of-mass in “unwrapped” form, by using the image flags associated with each atom. See the \textit{dump custom} command for a discussion of “unwrapped” coordinates. See the Atoms section of the \textit{read_data} command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the \textit{set image} command.

19.18.4 Output info

This compute calculates a global vector of length 3, which can be accessed by indices 1-3 by any command that uses global vector values from a compute as input. See the \textit{Howto output} doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The vector values will be in distance \textit{units}.

19.18.5 Restrictions

none

19.18.6 Related commands

19.18.7 Default

none

19.19 \texttt{compute com/chunk} command

19.19.1 Syntax

\texttt{compute ID group-ID com/chunk chunkID}

- ID, group-ID are documented in \textit{compute} command
- com/chunk = style name of this compute command
- chunkID = ID of \textit{compute chunk/atom} command
19.19.2 Examples

\texttt{compute 1 fluid com/chunk molchunk}

19.19.3 Description

Define a computation that calculates the center-of-mass for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a \texttt{compute chunk/atom} command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the \texttt{compute chunk/atom} and \textit{Howto chunk} doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the x,y,z coordinates of the center-of-mass for each chunk, which includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The \texttt{compute chunk/atom} command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

Note: The coordinates of an atom contribute to the chunk’s center-of-mass in “unwrapped” form, by using the image flags associated with each atom. See the \texttt{dump custom} command for a discussion of “unwrapped” coordinates. See the Atoms section of the \texttt{read_data} command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the \texttt{set image} command.

The simplest way to output the results of the compute com/chunk calculation to a file is to use the \texttt{fix ave/time} command, for example:

\texttt{compute ccl all chunk/atom molecule}
\texttt{compute myChunk all com/chunk ccl}
\texttt{fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector}

19.19.4 Output info

This compute calculates a global array where the number of rows = the number of chunks \textit{Nchunk} as calculated by the specified \texttt{compute chunk/atom} command. The number of columns = 3 for the x,y,z center-of-mass coordinates of each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the \textit{Howto output} doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in distance units.

19.20 compute contact/atom command

19.20.1 Syntax

compute ID group-ID contact/atom

• ID, group-ID are documented in compute command
• contact/atom = style name of this compute command

19.20.2 Examples

compute 1 all contact/atom

19.20.3 Description

Define a computation that calculates the number of contacts for each atom in a group.

The contact number is defined for finite-size spherical particles as the number of neighbor atoms which overlap the central particle, meaning that their distance of separation is less than or equal to the sum of the radii of the two particles.

The value of the contact number will be 0.0 for atoms not in the specified compute group.

19.20.4 Output info

This compute calculates a per-atom vector, whose values can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector values will be a number \( \geq 0.0 \), as explained above.
19.20.5 Restrictions

This compute requires that atoms store a radius as defined by the `atom_style sphere` command.

19.20.6 Related commands

`compute coord/atom`

19.20.7 Default

`none`

19.21 compute coord/atom command

Accelerator Variants: `coord/atom/kk`

19.21.1 Syntax

```
compute ID group-ID coord/atom cstyle args ...
```

- ID, group-ID are documented in `compute` command
- `coord/atom` = style name of this compute command
- `cstyle` = `cutoff` or `orientorder`

  `cutoff` args = `cutoff` [group group2-ID] typeN
  - `cutoff` = distance within which to count coordination neighbors
    - (distance units)
  - `group group2-ID` = select group-ID to restrict which atoms to consider
    - for coordination number (optional)
  - `typeN` = atom type for Nth coordination count (see asterisk form below)

  `orientorder` args = `orientorderID` `threshold`
  - `orientorderID` = ID of an `orientorder/atom` compute
  - `threshold` = minimum value of the product of two "connected" atoms

19.21.2 Examples

```
compute 1 all coord/atom cutoff 2.0
compute 1 all coord/atom cutoff 6.0 1 2
compute 1 all coord/atom cutoff 6.0 2*4 5*8 *
compute 1 solute coord/atom cutoff 2.0 group solvent
compute 1 all coord/atom orientorder 2 0.5
```
19.21.3 Description

This compute performs calculations between neighboring atoms to determine a coordination value. The specific calculation and the meaning of the resulting value depend on the cstyle keyword used.

The cutoff cstyle calculates one or more traditional coordination numbers for each atom. A coordination number is defined as the number of neighbor atoms with specified atom type(s), and optionally within the specified group, that are within the specified cutoff distance from the central atom. The compute group selects only the central atoms; all neighboring atoms, unless selected by type, type range, or group option, are included in the coordination number tally.

The optional group keyword allows to specify from which group atoms contribute to the coordination number. Default setting is group ‘all’.

The typeN keywords allow specification of which atom types contribute to each coordination number. One coordination number is computed for each of the typeN keywords listed. If no typeN keywords are listed, a single coordination number is calculated, which includes atoms of all types (same as the “*” format, see below).

The typeN keywords can be specified in one of two ways. An explicit numeric value can be used, as in the second example above. Or a wild-card asterisk can be used to specify a range of atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

The orientorder cstyle calculates the number of “connected” neighbor atoms J around each central atom I. For this cstyle, connected is defined by the orientational order parameter calculated by the compute orientorder/atom command. This cstyle thus allows one to apply the ten Wolde’s criterion to identify crystal-like atoms in a system, as discussed in ten Wolde.

The ID of the previously specified compute orientorder/atom command is specified as orientorderID. The compute must invoke its components option to calculate components of the Ybar_lm vector for each atoms, as described in its documentation. Note that orientorder/atom compute defines its own criteria for identifying neighboring atoms. If the scalar product (Ybar_Lm(i),Ybar_Lm(j)), calculated by the orientorder/atom compute is larger than the specified threshold, then I and J are connected, and the coordination value of I is incremented by one.

For all cstyle settings, all coordination values will be 0.0 for atoms not in the specified compute group.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

Note: If you have a bonded system, then the settings of special_bonds command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the special_bonds command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the coordination count. One way to get around this, is to write a dump file, and use the rerun command to compute the coordination for snapshots in the dump file. The rerun script can use a special_bonds command that includes all pairs in the neighbor list.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.
See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

19.21.4 Output info

For cstyle cutoff, this compute can calculate a per-atom vector or array. If single type1 keyword is specified (or if none are specified), this compute calculates a per-atom vector. If multiple typeN keywords are specified, this compute calculates a per-atom array, with N columns.

For cstyle orientorder, this compute calculates a per-atom vector.

These values can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector or array values will be a number >= 0.0, as explained above.

- ID, group-ID are documented in compute command
- damage/atom = style name of this compute command
19.22.2 Examples

```
compute 1 all damage/atom
```

19.22.3 Description

Define a computation that calculates the per-atom damage for each atom in a group. This is a quantity relevant for Peridynamics models. See this document for an overview of LAMMPS commands for Peridynamics modeling.

The “damage” of a Peridynamics particles is based on the bond breakage between the particle and its neighbors. If all the bonds are broken the particle is considered to be fully damaged.

See the PDLAMMPS user guide for a formal definition of “damage” and more details about Peridynamics as it is implemented in LAMMPS.

This command can be used with all the Peridynamic pair styles.

The damage value will be 0.0 for atoms not in the specified compute group.

19.22.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector values are unitless numbers (damage) >= 0.0.

19.22.5 Restrictions

This compute is part of the PERI package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

  phi = only currently allowed arg
  name = name of variable to set with phi
```

### 19.24.2 Examples

```plaintext
compute 1 all dihedral/local phi
compute 1 all dihedral/local phi v_cos set phi p
```

### 19.24.3 Description

Define a computation that calculates properties of individual dihedral interactions. The number of datums generated, aggregated across all processors, equals the number of dihedral angles in the system, modified by the group parameter as explained below.

The value \( \phi \) is the dihedral angle, as defined in the diagram on the dihedral_style doc page.

The value \( v_{\text{name}} \) can be used together with the set keyword to compute a user-specified function of the dihedral angle \( \phi \). The \( \text{name} \) specified for the \( v_{\text{name}} \) value is the name of an equal-style variable which should evaluate a formula based on a variable which will store the angle \( \phi \). This other variable must be an internal-style variable defined in the input script; its initial numeric value can be anything. It must be an internal-style variable, because this command resets its value directly. The set keyword is used to identify the name of this other variable associated with \( \phi \).

Note that the value of \( \phi \) for each angle which stored in the internal variable is in radians, not degrees.

As an example, these commands can be added to the bench/in.rhodo script to compute the cosine and cosine\(^2\) of every dihedral angle in the system and output the statistics in various ways:

```plaintext
variable p internal 0.0
variable cos equal cos(v_p)
variable cossq equal cos(v_p)\times cos(v_p)

compute 1 all property/local datom1 datom2 datom3 datom4 dtype
compute 2 all dihedral/local phi v_cos v_cossq set phi p
dump 1 all local 100 tmp.dump c_1[*] c_2[*]
compute 3 all reduce ave c_2[*]
thermo_style custom step temp press c_3[*]
fix 10 all ave/histo 10 100 -1 1 20 c_2[2] mode vector file tmp.histo
```

The dump local command will output the angle, cosine(angle), cosine\(^2\)(angle) for every dihedral in the system. The thermo_style command will print the average of those quantities via the compute reduce command with thermo output. And the fix ave/histo command will histogram the cosine(angle) values and write them to a file.

The local data stored by this command is generated by looping over all the atoms owned on a processor and their dihedrals. A dihedral will only be included if all 4 atoms in the dihedral are in the specified compute group.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a
particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, dihedral output from the `compute property/local` command can be combined with data from this command and output by the `dump local` command in a consistent way.

Here is an example of how to do this:

```bash
compute 1 all property/local dtype datom1 datom2 datom3 datom4
compute 2 all dihedral/local phi
```

### 19.24.4 Output info

This compute calculates a local vector or local array depending on the number of values. The length of the vector or number of rows in the array is the number of dihedrals. If a single value is specified, a local vector is produced. If two or more values are specified, a local array is produced where the number of columns = the number of values. The vector or array can be accessed by any command that uses local values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The output for `phi` will be in degrees.

### 19.24.5 Restrictions

none

### 19.25 compute dilatation/atom command

#### 19.25.1 Syntax

```bash
compute ID group-ID dilatation/atom
```

- ID, group-ID are documented in compute command
- dilatation/atom = style name of this compute command
19.25.2 Examples

```plaintext
compute 1 all dilatation/atom
```

19.25.3 Description

Define a computation that calculates the per-atom dilatation for each atom in a group. This is a quantity relevant for Peridynamics models. See this document for an overview of LAMMPS commands for Peridynamics modeling.

For small deformation, dilatation of is the measure of the volumetric strain.

The dilatation “theta” for each peridynamic particle I is calculated as a sum over its neighbors with unbroken bonds, where the contribution of the IJ pair is a function of the change in bond length (versus the initial length in the reference state), the volume fraction of the particles and an influence function. See the PDLAMMPS user guide for a formal definition of dilatation.

This command can only be used with a subset of the Peridynamic pair styles: peri/lps, peri/ves and peri/eps.

The dilatation value will be 0.0 for atoms not in the specified compute group.

19.25.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector values are unitless numbers (theta) >= 0.0.

19.25.5 Restrictions

This compute is part of the PERI package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.25.6 Related commands

`compute damage/atom`, `compute plasticity/atom`

19.25.7 Default

`none`

19.26 compute dipole/chunk command

19.26.1 Syntax

```plaintext
compute ID group-ID dipole/chunk chunkID charge-correction
```

- ID, group-ID are documented in `compute` command
- dipole/chunk = style name of this compute command
19.26.2 Examples

```plaintext
compute 1 fluid dipole/chunk molchunk
compute dw water dipole/chunk 1 geometry
```

19.26.3 Description

Define a computation that calculates the dipole vector and total dipole for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the x,y,z coordinates of the dipole vector and the total dipole moment for each chunk, which includes all effects due to atoms passing through periodic boundaries. For chunks with a net charge the resulting dipole is made position independent by subtracting the position vector of the center of mass or geometric center times the net charge from the computed dipole vector.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

Note: The coordinates of an atom contribute to the chunk’s dipole in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

The simplest way to output the results of the compute com/chunk calculation to a file is to use the `fix ave/time` command, for example:

```plaintext
compute ccl all chunk/atom molecule
compute myChunk all dipole/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

19.26.4 Output info

This compute calculates a global array where the number of rows = the number of chunks $N_{chunk}$ as calculated by the specified `compute chunk/atom` command. The number of columns = 4 for the x,y,z dipole vector components and the total dipole of each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in dipole units, i.e. charge units times distance units.
19.26.5 Restrictions

none

19.27 compute displace/atom command

19.27.1 Syntax

compute ID group-ID displace/atom

- ID, group-ID are documented in compute command
- displace/atom = style name of this compute command
- zero or more keyword/arg pairs may be appended
- keyword = refresh
  replace arg = name of per-atom variable

19.27.2 Examples

compute 1 all displace/atom
compute 1 all displace/atom refresh myVar

19.27.3 Description

Define a computation that calculates the current displacement of each atom in the group from its original (reference) coordinates, including all effects due to atoms passing through periodic boundaries.

A vector of four quantities per atom is calculated by this compute. The first 3 elements of the vector are the dx,dy,dz displacements. The fourth component is the total displacement, i.e. sqrt(dx*dx + dy*dy + dz*dz).

The displacement of an atom is from its original position at the time the compute command was issued. The value of the displacement will be 0.0 for atoms not in the specified compute group.

Note: Initial coordinates are stored in “unwrapped” form, by using the image flags associated with each atom. See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the set image command.
Note: If you want the quantities calculated by this compute to be continuous when running from a restart file, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with time=0 atom coordinates from the restart file.

The refresh option can be used in conjunction with the “dump_modify refresh” command to generate incremental dump files.

The definition and motivation of an incremental dump file is as follows. Instead of outputting all atoms at each snapshot (with some associated values), you may only wish to output the subset of atoms with a value that has changed in some way compared to the value the last time that atom was output. In some scenarios this can result in a dramatically smaller dump file. If desired, by post-processing the sequence of snapshots, the values for all atoms at all timesteps can be inferred.

A concrete example using this compute, is a simulation of atom diffusion in a solid, represented as atoms on a lattice. Diffusive hops are rare. Imagine that when a hop occurs an atom moves more than a distance $D_{hop}$. For any snapshot we only want to output atoms that have hopped since the last snapshot. This can be accomplished with something like the following commands:

```plaintext
write_dump all custom tmp.dump id type x y z  # see comment below

variable Dhop equal 0.6
variable check atom "c_dsp[4] > v_Dhop"
compute dsp all displace/atom refresh check
dump 1 all custom 100 tmp.dump id type x y z
dump_modify 1 append yes thresh c_dsp[4] > $Dhop &
          refresh c_dsp delay 100
```

The dump_modify thresh command will only output atoms that have displaced more than 0.6 Angstroms on each snapshot (assuming metal units). The dump_modify refresh option triggers a call to this compute at the end of every dump.

The refresh argument for this compute is the ID of an atom-style variable which calculates a Boolean value (0 or 1) based on the same criterion used by dump_modify thresh. This compute evaluates the atom-style variable. For each atom that returns 1 (true), the original (reference) coordinates of the atom (stored by this compute) are updated.

The effect of these commands is that a particular atom will only be output in the dump file on the snapshot after it makes a diffusive hop. It will not be output again until it makes another hop.

Note that in the first snapshot of a subsequent run, no atoms will be typically be output. That is because the initial displacement for all atoms is 0.0. If an initial dump snapshot is desired, containing the initial reference positions of all atoms, one way to do this is illustrated above. An initial write_dump command can be used before the first run. It will contain the positions of all the atoms. Options in the dump_modify command above will append new output to that same file and delay the output until a later timestep. The delay setting avoids a second time = 0 snapshot which would be empty.
19.27.4 Output info

This compute calculates a per-atom array with 4 columns, which can be accessed by indices 1-4 by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The per-atom array values will be in distance *units*.

This compute supports the *refresh* option as explained above, for use in conjunction with *dump_modify refresh* to generate incremental dump files.

19.28 compute dpd command

19.28.1 Syntax

```plaintext
compute ID group-ID dpd
```

- ID, group-ID are documented in *compute* command
- dpd = style name of this compute command

19.28.2 Examples

```plaintext
compute 1 all dpd
```

19.28.3 Description

Define a computation that accumulates the total internal conductive energy \( U_{\text{cond}} \), the total internal mechanical energy \( U_{\text{mech}} \), the total chemical energy \( U_{\text{chem}} \) and the harmonic average of the internal temperature \( \theta_{\text{avg}} \) for the entire system of particles. See the *compute dpd/atom* command if you want per-particle internal energies and internal temperatures.
The system internal properties are computed according to the following relations:

\[ U^{\text{cond}} = \sum_{i=1}^{N} u_i^{\text{cond}} \]

\[ U^{\text{mech}} = \sum_{i=1}^{N} u_i^{\text{mech}} \]

\[ U^{\text{chem}} = \sum_{i=1}^{N} u_i^{\text{chem}} \]

\[ U = \sum_{i=1}^{N} (u_i^{\text{cond}} + u_i^{\text{mech}} + u_i^{\text{chem}}) \]

\[ \theta_{\text{avg}} = \left( \frac{1}{N} \sum_{i=1}^{N} \frac{1}{\theta_i} \right)^{-1} \]

where \( N \) is the number of particles in the system.

### 19.28.4 Output info

This compute calculates a global vector of length 5 (\( U^{\text{cond}}, U^{\text{mech}}, U^{\text{chem}}, \theta_{\text{avg}}, N \)), which can be accessed by indices 1-5. See the *Howto output* doc page for an overview of LAMMPS output options.

The vector values will be in energy and temperature units.

### 19.28.5 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

This command also requires use of the *atom_style dpd* command.

19.31 compute entropy/atom command

19.31.1 Syntax

\[
\text{compute ID group-ID entropy/atom sigma cutoff keyword value ...}
\]

- ID, group-ID are documented in compute command
- entropy/atom = style name of this compute command
- sigma = width of gaussians used in the g(r) smoothing
- cutoff = cutoff for the g(r) calculation
- one or more keyword/value pairs may be appended

Keyword = avg or local
  avg values = yes or no cutoff2
    yes = average the pair entropy over neighbors
    no = do not average the pair entropy over neighbors
  cutoff2 = cutoff for the averaging over neighbors
  local values = yes or no = use the local density around each atom to normalize the g(r)

19.31.2 Examples

```
compute 1 all entropy/atom 0.25 5.
compute 1 all entropy/atom 0.25 5. avg yes 5.
compute 1 all entropy/atom 0.125 7.3 avg yes 5.1 local yes
```
19.31.3 Description

Define a computation that calculates the pair entropy fingerprint for each atom in the group. The fingerprint is useful to distinguish between ordered and disordered environments, for instance liquid and solid-like environments, or glassy and crystalline-like environments. Some applications could be the identification of grain boundaries, a melt-solid interface, or a solid cluster emerging from the melt. The advantage of this parameter over others is that no a priori information about the solid structure is required.

This parameter for atom i is computed using the following formula from \((Piaggi)\) and \((Netleton)\),

\[
s^i_S = -2\pi\rho k_B \int_0^{r_m} [g(r) \ln g(r) - g(r) + 1] r^2 dr
\]

where \(r\) is a distance, \(g(r)\) is the radial distribution function of atom i and \(\rho\) is the density of the system. The \(g(r)\) computed for each atom i can be noisy and therefore it is smoothed using:

\[
g^i_m(r) = \frac{1}{4\pi \rho r^2} \sum_j \frac{1}{\sqrt{2\pi \sigma^2}} e^{-\frac{(r-r_{ij})^2}{2\sigma^2}}
\]

where the sum in j goes through the neighbors of atom i, and \(\sigma\) is a parameter to control the smoothing.

The input parameters are \textit{sigma} the smoothing parameter \(\sigma\), and the \textit{cutoff} for the calculation of \(g(r)\).

If the keyword \textit{avg} has the setting \textit{yes}, then this compute also averages the parameter over the neighbors of atom i according to:

\[
\langle s^i_S \rangle = \frac{\sum_j s^j_S + s^i_S}{N+1}
\]

where the sum j goes over the neighbors of atom i and N is the number of neighbors. This procedure provides a sharper distinction between order and disorder environments. In this case the input parameter \textit{cutoff2} is the cutoff for the averaging over the neighbors and must also be specified.

If the \textit{avg yes} option is used, the effective cutoff of the neighbor list should be \textit{cutoff}+\textit{cutoff2} and therefore it might be necessary to increase the skin of the neighbor list with:

\texttt{neighbor <skin distance> bin}

See \texttt{neighbor} for details.

If the \textit{local yes} option is used, the \(g(r)\) is normalized by the local density around each atom, that is to say the density around each atom is the number of neighbors within the neighbor list cutoff divided by the corresponding volume. This option can be useful when dealing with inhomogeneous systems such as those that have surfaces.

Here are typical input parameters for fcc aluminum (lattice constant 4.05 Angstroms),

\texttt{compute 1 all entropy/atom 0.25 5.7 avg yes 3.7}

and for bcc sodium (lattice constant 4.23 Angstroms),

\texttt{compute 1 all entropy/atom 0.25 7.3 avg yes 5.1}
19.31.4 Output info

By default, this compute calculates the pair entropy value for each atom as a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The pair entropy values have units of the Boltzmann constant. They are always negative, and lower values (lower entropy) correspond to more ordered environments.

19.31.5 Restrictions

This compute is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.31.6 Related commands

19.32 compute erotate/asphere command

19.32.1 Syntax

```
compute ID group-ID erotate/asphere
```

- ID, group-ID are documented in compute command
- erotate/asphere = style name of this compute command

19.32.2 Examples

```
compute 1 all erotate/asphere
```
19.32.3 Description

Define a computation that calculates the rotational kinetic energy of a group of aspherical particles. The aspherical particles can be ellipsoids, or line segments, or triangles. See the `atom_style` and `read_data` commands for descriptions of these options.

For all 3 types of particles, the rotational kinetic energy is computed as 1/2 I w^2, where I is the inertia tensor for the aspherical particle and w is its angular velocity, which is computed from its angular momentum if needed.

**Note:** For 2d models, ellipsoidal particles are treated as ellipsoids, not ellipses, meaning their moments of inertia will be the same as in 3d.

19.32.4 Output info

This compute calculates a global scalar (the KE). This value can be used by any command that uses a global scalar value from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy *units*.

19.32.5 Restrictions

This compute requires that ellipsoidal particles atoms store a shape and quaternion orientation and angular momentum as defined by the `atom_style ellipsoid` command.

This compute requires that line segment particles atoms store a length and orientation and angular velocity as defined by the `atom_style line` command.

This compute requires that triangular particles atoms store a size and shape and quaternion orientation and angular momentum as defined by the `atom_style tri` command.

All particles in the group must be finite-size. They cannot be point particles.

\]

- ID, group-ID are documented in \textit{compute} command
- erotate/rigid = style name of this compute command
- fix-ID = ID of rigid body fix

19.33.2 Examples

\texttt{compute 1 all erotate/rigid myRigid}

19.33.3 Description

Define a computation that calculates the rotational kinetic energy of a collection of rigid bodies, as defined by one of the \textit{fix rigid} command variants. The rotational energy of each rigid body is computed as $\frac{1}{2} I W_{body}^2$, where $I$ is the inertia tensor for the rigid body, and $W_{body}$ is its angular velocity vector. Both $I$ and $W_{body}$ are in the frame of reference of the rigid body, i.e. $I$ is diagonalized. The \textit{fix-ID} should be the ID of one of the \textit{fix rigid} commands which defines the rigid bodies. The group specified in the compute command is ignored. The rotational energy of all the rigid bodies defined by the fix rigid command in included in the calculation.

19.33.4 Output info

This compute calculates a global scalar (the summed rotational energy of all the rigid bodies). This value can be used by any command that uses a global scalar value from a compute as input. See the \textit{Howto output} doc page for an overview of LAMMPS output options. The scalar value calculated by this compute is “extensive”. The scalar value will be in energy \textit{units}.

19.33.5 Restrictions

This compute is part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

```

- ID, group-ID are documented in `compute` command
- `erotate/sphere` = style name of this compute command

19.34.2 Examples

```
compute 1 all `erotate/sphere`
```

19.34.3 Description

Define a computation that calculates the rotational kinetic energy of a group of spherical particles.

The rotational energy is computed as \( 1/2 I \omega^2 \), where \( I \) is the moment of inertia for a sphere and \( \omega \) is the particle’s angular velocity.

**Note:** For 2D models, particles are treated as spheres, not disks, meaning their moment of inertia will be the same as in 3D.

19.34.4 Output info

This compute calculates a global scalar (the KE). This value can be used by any command that uses a global scalar value from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy units.
19.34.5 Restrictions

This compute requires that atoms store a radius and angular velocity (omega) as defined by the *atom_style sphere* command.

All particles in the group must be finite-size spheres or point particles. They cannot be aspherical. Point particles will not contribute to the rotational energy.

19.36 compute event/displace command

19.36.1 Syntax

```plaintext
compute ID group-ID event/displace threshold
```

- ID, group-ID are documented in compute command
- event/displace = style name of this compute command
- threshold = minimum distance any particle must move to trigger an event (distance units)

19.36.2 Examples

```plaintext
compute 1 all event/displace 0.5
```

19.36.3 Description

Define a computation that flags an “event” if any particle in the group has moved a distance greater than the specified threshold distance when compared to a previously stored reference state (i.e. the previous event). This compute is typically used in conjunction with the prd and tad commands, to detect if a transition to a new minimum energy basin has occurred.

This value calculated by the compute is equal to 0 if no particle has moved far enough, and equal to 1 if one or more particles have moved further than the threshold distance.

**Note:** If the system is undergoing significant center-of-mass motion, due to thermal motion, an external force, or an initial net momentum, then this compute will not be able to distinguish that motion from local atom displacements and may generate “false positives.”
19.36.4 Output info

This compute calculates a global scalar (the flag). This value can be used by any command that uses a global scalar value from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The scalar value will be a 0 or 1 as explained above.

19.36.5 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

19.36.6 Related commands

19.37 compute fep command

19.37.1 Syntax

```
compute ID group-ID fep temp attribute args ... keyword value ...
```

- ID, group-ID are documented in the compute command
- fep = name of this compute command
- temp = external temperature (as specified for constant-temperature run)
- one or more attributes with args may be appended
- attribute = pair or atom
  
  **pair** args = pstyle pparam I J v_delta
  pstyle = pair style name, e.g. lj/cut
  pparam = parameter to perturb
  I, J = type pair(s) to set parameter for
  v_delta = variable with perturbation to apply (in the units of the pparam)
  
  **atom** args = aparam I v_delta
  aparam = parameter to perturb
  I = type to set parameter for
  v_delta = variable with perturbation to apply (in the units of the aparam)

- zero or more keyword/value pairs may be appended
- keyword = tail or volume
tail value = no or yes
  no = ignore tail correction to pair energies (usually small in fep)
  yes = include tail correction to pair energies

volume value = no or yes
  no = ignore volume changes (e.g. in NVE or NVT trajectories)
  yes = include volume changes (e.g. in NpT trajectories)

19.37.2 Examples

```plaintext
compute 1 all fep 298 pair lj/cut epsilon 1 * v_delta pair lj/cut sigma 1 * v_delta
→ volume yes

compute 1 all fep 300 atom charge 2 v_delta
```

19.37.3 Description

Apply a perturbation to parameters of the interaction potential and recalculate the pair potential energy without changing the atomic coordinates from those of the reference, unperturbed system. This compute can be used to calculate free energy differences using several methods, such as free-energy perturbation (FEP), finite-difference thermodynamic integration (FDTI) or Bennet’s acceptance ratio method (BAR).

The potential energy of the system is decomposed in three terms: a background term corresponding to interaction sites whose parameters remain constant, a reference term $U_0$ corresponding to the initial interactions of the atoms that will undergo perturbation, and a term $U_1$ corresponding to the final interactions of these atoms:

$$U(\lambda) = U_{bg} + U_1(\lambda) + U_0(\lambda)$$

A coupling parameter $\lambda$ varying from 0 to 1 connects the reference and perturbed systems:

$$\lambda = 0 \quad \Rightarrow \quad U = U_{bg} + U_0$$
$$\lambda = 1 \quad \Rightarrow \quad U = U_{bg} + U_1$$

It is possible but not necessary that the coupling parameter (or a function thereof) appears as a multiplication factor of the potential energy. Therefore, this compute can apply perturbations to interaction parameters that are not directly proportional to the potential energy (e.g. $\sigma$ in Lennard-Jones potentials).

This command can be combined with `fix adapt` to perform multistage free-energy perturbation calculations along stepwise alchemical transformations during a simulation run:

$$\Delta^1_0 A = \sum_{i=0}^{n-1} \Delta^1_{\lambda_i} A = -kT \sum_{i=0}^{n-1} \ln \left\langle \exp \left( -\frac{U(\lambda_{i+1}) - U(\lambda_i)}{kT} \right) \right\rangle_{\lambda_i}$$

This compute is suitable for the finite-difference thermodynamic integration (FDTI) method (Mezei), which is based on an evaluation of the numerical derivative of the free energy by a perturbation method using a very small $\delta$:

$$\Delta^1_0 A = \int_{\lambda=0}^{\lambda=1} \left( \frac{\partial A(\lambda)}{\partial \lambda} \right)_{\lambda} d\lambda \approx \sum_{i=0}^{n-1} w_i \frac{A(\lambda_i + \delta) - A(\lambda_i)}{\delta}$$

where $w_i$ are weights of a numerical quadrature. The `fix adapt` command can be used to define the stages of $\lambda$ at which the derivative is calculated and averaged.

The compute fep calculates the exponential Boltzmann term and also the potential energy difference $U_1 - U_0$. By choosing a very small perturbation $\delta$ the thermodynamic integration method can be implemented using a numerical evaluation of the derivative of the potential energy with respect to $\lambda$:

$$\Delta^1_0 A = \int_{\lambda=0}^{\lambda=1} \left( \frac{\partial U(\lambda)}{\partial \lambda} \right)_{\lambda} d\lambda \approx \sum_{i=0}^{n-1} w_i \left( \frac{U(\lambda_i + \delta) - U(\lambda_i)}{\delta} \right)_{\lambda_i}$$
Another technique to calculate free energy differences is the acceptance ratio method (Bennet), which can be implemented by calculating the potential energy differences with $\delta = 1.0$ on both the forward and reverse routes:

$$\langle \frac{1}{1 + \exp \left[ (U_1 - U_0 - \Delta V_A) / kT \right] \rangle_0 = \langle \frac{1}{1 + \exp \left[ (U_0 - U_1 + \Delta V_A) / kT \right] \rangle_1$$

The value of the free energy difference is determined by numerical root finding to establish the equality.

Concerning the choice of how the atomic parameters are perturbed in order to setup an alchemical transformation route, several strategies are available, such as single-topology or double-topology strategies (Pearlman). The latter does not require modification of bond lengths, angles or other internal coordinates.

NOTES: This compute command does not take kinetic energy into account, therefore the masses of the particles should not be modified between the reference and perturbed states, or along the alchemical transformation route. This compute command does not change bond lengths or other internal coordinates (Boresch, Karplus).

The pair attribute enables various parameters of potentials defined by the pair_style and pair_coeff commands to be changed, if the pair style supports it.

The pstyle argument is the name of the pair style. For example, pstyle could be specified as “lj/cut”. The pparam argument is the name of the parameter to change. This is a list of pair styles and parameters that can be used with this compute. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

Note that it is easy to add new potentials and their parameters to this list. All it typically takes is adding an extract() method to the pair_*.cpp file associated with the potential.
Similar to the pair_coeff command, I and J can be specified in one of two ways. Explicit numeric values can be used for each, as in the first example above. I <= J is required. LAMMPS sets the coefficients for the symmetric J,I interaction to the same values. A wild-card asterisk can be used in place of or in conjunction with the I,J arguments to set the coefficients for multiple pairs of atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that only type pairs with I <= J are considered; if asterisks imply type pairs where J < I, they are ignored.

If pair_style hybrid or hybrid/overlay is being used, then the pstyle will be a sub-style name. You must specify I,J arguments that correspond to type pair values defined (via the pair_coeff command) for that sub-style.

The v_name argument for keyword pair is the name of an equal-style variable which will be evaluated each time this compute is invoked. It should be specified as v_name, where name is the variable name.

The atom attribute enables atom properties to be changed. The aparam argument is the name of the parameter to change. This is the current list of atom parameters that can be used with this compute:

- charge = charge on particle

The v_name argument for keyword pair is the name of an equal-style variable which will be evaluated each time this compute is invoked. It should be specified as v_name, where name is the variable name.

The tail keyword controls the calculation of the tail correction to “van der Waals” pair energies beyond the cutoff, if this has been activated via the pair_modify command. If the perturbation is small, the tail contribution to the energy difference between the reference and perturbed systems should be negligible.

If the keyword volume = yes, then the Boltzmann term is multiplied by the volume so that correct ensemble averaging can be performed over trajectories during which the volume fluctuates or changes (Allen and Tildesley):

\[
\Delta_{10} A = -kT \sum_{i=0}^{n-1} \ln \left( \frac{V \exp \left( \frac{-U_{i+1} - U_i}{kT} \right)}{\langle V \rangle_{\lambda_i}} \right)_{\lambda_i}
\]

19.37.4 Output info

This compute calculates a global vector of length 3 which contains the energy difference ( \( U_1 - U_0 \) ) as c_ID[1], the Boltzmann factor \( \exp(-U_1 - U_0)/kT) \), or \( V \exp(-(U_1 - U_0)/kT) \), as c_ID[2] and the volume of the simulation box V as c_ID[3]. \( U_1 \) is the pair potential energy obtained with the perturbed parameters and \( U_0 \) is the pair potential energy obtained with the unperturbed parameters. The energies include kspace terms if these are used in the simulation.

These output results can be used by any command that uses a global scalar or vector from a compute as input. See the Howto output doc page for an overview of LAMMPS output options. For example, the computed values can be averaged using fix ave/time.

The values calculated by this compute are “extensive”.

1522 Chapter 19. Computes
19.37.5 Restrictions

This compute is distributed as the USER-FEP package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.38.2 Examples

\begin{verbatim}
compute 1 all global/atom c_chunk c_com[*]
\end{verbatim}

19.38.3 Description

Define a calculation that assigns global values to each atom from vectors or arrays of global values. The specified index parameter is used to determine which global value is assigned to each atom.

The index parameter must reference a per-atom vector or array from a compute or fix or the evaluation of an atom-style variable. Each input value must reference a global vector or array from a compute or fix or the evaluation of an vector-style variable. Details are given below.

The index value for an atom is used as a index I (from 1 to N) into the vector associated with each of the input values. The Ith value from the input vector becomes one output value for that atom. If the atom is not in the specified group, or the index I < 1 or I > M, where M is the actual length of the input vector, then an output value of 0.0 is assigned to the atom.

An example of how this command is useful, is in the context of “chunks” which are static or dynamic subsets of atoms. The compute chunk/atom command assigns unique chunk IDs to each atom. It’s output can be used as the index parameter for this command. Various other computes with “chunk” in their style name, such as compute com/chunk or compute msd/chunk, calculate properties for each chunk. The output of these commands are global vectors or arrays, with one or more values per chunk, and can be used as input values for this command. This command will then assign the global chunk value to each atom in the chunk, producing a per-atom vector or per-atom array as output. The per-atom values can then be output to a dump file or used by any command that uses per-atom values from a compute as input, as discussed on the Howto output doc page.

As a concrete example, these commands will calculate the displacement of each atom from the center-of-mass of the molecule it is in, and dump those values to a dump file. In this case, each molecule is a chunk.

\begin{verbatim}
compute ccl all chunk/atom molecule
compute myChunk all com/chunk ccl
compute prop all property/atom xu yu zu
compute glob all global/atom c_ccl c_myChunk[*]
variable dx atom c_prop[1]-c_glob[1]
variable dy atom c_prop[2]-c_glob[2]
variable dz atom c_prop[3]-c_glob[3]
variable dist atom sqrt(v_dx*v_dx+v_dy*v_dy+v_dz*v_dz)
dump_modify 1 sort id
\end{verbatim}

You can add these commands to the bench/in.chain script to see how they work.

Note that for input values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the size of the vector (for mode = scalar) or the number of columns in the array (for mode = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 compute global/atom commands are equivalent, since the compute com/chunk command creates a global array with 3 columns:
This section explains the `index` parameter. Note that it must reference per-atom values, as contrasted with the `input` values which must reference global values.

Note that all of these options generate floating point values. When they are used as an index into the specified input vectors, they simple rounded down to convert the value to integer indices. The final values should range from 1 to N (inclusive), since they are used to access values from N-length vectors.

If `index` begins with “c_”, a compute ID must follow which has been previously defined in the input script. The compute must generate per-atom quantities. See the individual `compute` doc page for details. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and add them to LAMMPS. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If `index` begins with “f_”, a fix ID must follow which has been previously defined in the input script. The Fix must generate per-atom quantities. See the individual `fix` doc page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute global/atom references the values, else an error results. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the fix is used. Users can also write code for their own fix style and add them to LAMMPS. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If `index` begins with “v_”, a variable name must follow which has been previously defined in the input script. It must be an atom-style variable. Atom-style variables can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to use as `index`.

This section explains the kinds of `input` values that can be used. Note that inputs reference global values, as contrasted with the `index` parameter which must reference per-atom values.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. The compute must generate a global vector or array. See the individual `compute` doc page for details. If no bracketed integer is appended, the vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the array calculated by the compute is used. Users can also write code for their own compute styles and add them to LAMMPS. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. The fix must generate a global vector or array. See the individual `fix` doc page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute global/atom references the values, else an error results. If no bracketed integer is appended, the vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the array calculated by the fix is used. Users can also write code for their own fix style and add them to LAMMPS. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. It must be a vector-style variable. Vector-style variables can reference thermodynamic keywords and various other attributes of atoms, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating a vector of global quantities which the `index` parameter will reference for assignment of global values to atoms.

19.38. compute global/atom command 1525
19.38.4 Output info

If a single input is specified this compute produces a per-atom vector. If multiple inputs are specified, this compute produces a per-atom array values, where the number of columns is equal to the number of inputs specified. These values can be used by any command that uses per-atom vector or array values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector or array values will be in whatever units the corresponding input values are in.

19.39.2 Examples

```plaintext
compute 1 lower group/group upper
compute 1 lower group/group upper kspace yes
compute mine fluid group/group wall
```

19.39.3 Description

Define a computation that calculates the total energy and force interaction between two groups of atoms: the compute group and the specified group2. The two groups can be the same.

If the pair keyword is set to yes, which is the default, then the interaction energy will include a pair component which is defined as the pairwise energy between all pairs of atoms where one atom in the pair is in the first group and the other is in the second group. Likewise, the interaction force calculated by this compute will include the force on the compute group atoms due to pairwise interactions with atoms in the specified group2.

Note: The energies computed by the pair keyword do not include tail corrections, even if they are enabled via the pair_modify command.

If the molecule keyword is set to inter or intra than an additional check is made based on the molecule IDs of the two atoms in each pair before including their pairwise interaction energy and force. For the inter setting, the two atoms must be in different molecules. For the intra setting, the two atoms must be in the same molecule.

If the kspace keyword is set to yes, which is not the default, and if a kspace_style is defined, then the interaction energy will include a Kspace component which is the long-range Coulombic energy between all the atoms in the first group and all the atoms in the second group. Likewise, the interaction force calculated by this compute will include the force on the compute group atoms due to long-range Coulombic interactions with atoms in the specified group2.

Normally the long-range Coulombic energy converges only when the net charge of the unit cell is zero. However, one can assume the net charge of the system is neutralized by a uniform background plasma, and a correction to the system energy can be applied to reduce artifacts. For more information see (Bogusz). If the boundary keyword is set to yes, which is the default, and kspace contributions are included, then this energy correction term will be added to the total group-group energy. This correction term does not affect the force calculation and will be zero if one or both of the groups are charge neutral. This energy correction term is the same as that included in the regular Ewald and PPPM routines.

Note: The molecule setting only affects the group/group contributions calculated by the pair keyword. It does not affect the group/group contributions calculated by the kspace keyword.

This compute does not calculate any bond or angle or dihedral or improper interactions between atoms in the two groups.

The pairwise contributions to the group-group interactions are calculated by looping over a neighbor list. The Kspace contribution to the group-group interactions require essentially the same amount of work (FFTs, Ewald summation) as computing long-range forces for the entire system. Thus it can be costly to invoke this compute too frequently.

Note: If you have a bonded system, then the settings of special_bonds command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the special_bonds command, and means those pairwise interactions do not appear in the neighbor list. Because this compute uses a neighbor list, it also means those pairs will not be included in the group/group interaction. This does not apply when using long-range coulomb interactions (coul/long, coul/msm, coul/wolf) or similar. One way to get around this would be to set
special_bond scaling factors to very tiny numbers that are not exactly zero (e.g. 1.0e-50). Another workaround is to write a dump file, and use the rerun command to compute the group/group interactions for snapshots in the dump file. The rerun script can use a special_bonds command that includes all pairs in the neighbor list.

If you desire a breakdown of the interactions into a pairwise and Kspace component, simply invoke the compute twice with the appropriate yes/no settings for the pair and kspace keywords. This is no more costly than using a single compute with both keywords set to yes. The individual contributions can be summed in a variable if desired.

This document describes how the long-range group-group calculations are performed.

### 19.39.4 Output info

This compute calculates a global scalar (the energy) and a global vector of length 3 (force), which can be accessed by indices 1-3. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

Both the scalar and vector values calculated by this compute are “extensive”. The scalar value will be in energy units. The vector values will be in force units.

### 19.39.5 Restrictions

Not all pair styles can be evaluated in a pairwise mode as required by this compute. For example, 3-body and other many-body potentials, such as Tersoff and Stillinger-Weber cannot be used. EAM potentials will re-use previously computed embedding term contributions, so the computed pairwise forces and energies are based on the whole system and not valid if particles have been moved since.

Not all Kspace styles support the calculation of group/group interactions. The regular ewald and pppm styles do.

### 19.39.6 Related commands

none

### 19.39.7 Default

The option defaults are pair = yes, kspace = no, boundary = yes, molecule = off.

### 19.40 compute gyration command

#### 19.40.1 Syntax

```
compute ID group-ID gyration
```

- ID, group-ID are documented in compute command
- gyration = style name of this compute command
19.40.2 Examples

compute 1 molecule gyration

19.40.3 Description

Define a computation that calculates the radius of gyration $R_g$ of the group of atoms, including all effects due to atoms passing through periodic boundaries.

$R_g$ is a measure of the size of the group of atoms, and is computed as the square root of the $R_g^2$ value in this formula

$$R_g^2 = \frac{1}{M} \sum_i m_i (r_i - r_{cm})^2$$

where $M$ is the total mass of the group, $r_{cm}$ is the center-of-mass position of the group, and the sum is over all atoms in the group.

A $R_g^2$ tensor, stored as a 6-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formula, except that $(r_i - r_{cm})^2$ is replaced by $(r_{i,x} - r_{cm,x}) \cdot (r_{i,y} - r_{cm,y})$ for the xy component, and so on. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz. Note that unlike the scalar $R_g$, each of the 6 values of the tensor is effectively a “squared” value, since the cross-terms may be negative and taking a sqrt() would be invalid.

Note: The coordinates of an atom contribute to $R_g$ in “unwrapped” form, by using the image flags associated with each atom. See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the set image command.

19.40.4 Output info

This compute calculates a global scalar ($R_g$) and a global vector of length 6 ($R_g^2$ tensor), which can be accessed by indices 1-6. These values can be used by any command that uses a global scalar value or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar and vector values calculated by this compute are “intensive”. The scalar and vector values will be in distance and distance^2 units respectively.

19.41.1 Syntax

```plaintext
compute ID group-ID gyration/chunk chunkID keyword value ...
```

- ID, group-ID are documented in `compute` command
- gyration/chunk = style name of this compute command
- chunkID = ID of `compute chunk/atom` command
- zero or more keyword/value pairs may be appended
- keyword = `tensor`
  value = none

19.41.2 Examples

```plaintext
compute 1 molecule gyration/chunk molchunk
compute 2 molecule gyration/chunk molchunk tensor
```

19.41.3 Description

Define a computation that calculates the radius of gyration $R_g$ for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the radius of gyration $R_g$ for each chunk, which includes all effects due to atoms passing through periodic boundaries.

$R_g$ is a measure of the size of a chunk, and is computed by this formula

$$ R_g^2 = \frac{1}{M} \sum_i m_i (r_i - r_{cm})^2 $$

where $M$ is the total mass of the chunk, $r_{cm}$ is the center-of-mass position of the chunk, and the sum is over all atoms in the chunk.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

If the `tensor` keyword is specified, then the scalar $R_g$ value is not calculated, but an $R_g$ tensor is instead calculated for each chunk. The formula for the components of the tensor is the same as the above formula, except that $(r_i - r_{cm})^2$
is replaced by \((r_{i,x} - r_{cm,x}) \cdot (r_{i,y} - r_{cm,y})\) for the xy component, and so on. The 6 components of the tensor are ordered xx, yy, zz, xy, xz, yz.

**Note:** The coordinates of an atom contribute to \(R_g\) in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

The simplest way to output the results of the compute gyration/chunk calculation to a file is to use the `fix ave/time` command, for example:

```lmp
compute ccl all chunk/atom molecule
compute myChunk all gyration/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk file tmp.out mode vector
```

### 19.41.4 Output info

This compute calculates a global vector if the `tensor` keyword is not specified and a global array if it is. The length of the vector or number of rows in the array = the number of chunks \(N_{chunk}\) as calculated by the specified `compute chunk/atom` command. If the `tensor` keyword is specified, the global array has 6 columns. The vector or array can be accessed by any command that uses global values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

All the vector or array values calculated by this compute are “intensive”. The vector or array values will be in distance units, since they are the square root of values represented by the formula above.

### 19.42 compute gyration/shape command

#### 19.42.1 Syntax

```
compute ID group-ID gyration/shape compute-ID
```

- `ID, group-ID` are documented in `compute` command
- `gyration/shape = style name of this compute command`
• compute-ID = ID of `compute gyration` command

19.42.2 Examples

```
compute 1 molecule gyration/shape pe
```

19.42.3 Description

Define a computation that calculates the eigenvalues of the gyration tensor of a group of atoms and three shape parameters. The computation includes all effects due to atoms passing through periodic boundaries.

The three computed shape parameters are the asphericity, $b$, the acylindricity, $c$, and the relative shape anisotropy, $k$:

\[
\begin{align*}
  c &= l_z - 0.5(l_y + l_x) \\
  b &= l_y - l_x \\
  k &= \frac{3}{2} \left( \frac{l_x^2 + l_y^2 + l_z^2}{(l_x + l_y + l_z)^2} - \frac{1}{2} \right)
\end{align*}
\]

where $l_x \leq l_y \leq l_z$ are the three eigenvalues of the gyration tensor. A general description of these parameters is provided in (Mattice) while an application to polymer systems can be found in (Theodorou). The asphericity is always non-negative and zero only when the three principal moments are equal. This zero condition is met when the distribution of particles is spherically symmetric (hence the name asphericity) but also whenever the particle distribution is symmetric with respect to the three coordinate axes, e.g., when the particles are distributed uniformly on a cube, tetrahedron or other Platonic solid. The acylindricity is always non-negative and zero only when the two principal moments are equal. This zero condition is met when the distribution of particles is cylindrically symmetric (hence the name, acylindricity), but also whenever the particle distribution is symmetric with respect to the two coordinate axes, e.g., when the particles are distributed uniformly on a regular prism. The relative shape anisotropy is bounded between zero (if all points are spherically symmetric) and one (if all points lie on a line).

**Note:** The coordinates of an atom contribute to the gyration tensor in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

19.42.4 Output info

This compute calculates a global vector of length 6, which can be accessed by indices 1-6. The first three values are the eigenvalues of the gyration tensor followed by the asphericity, the acylindricity and the relative shape anisotropy. The computed values can be used by any command that uses global vector values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The vector values calculated by this compute are “intensive”. The first five vector values will be in distance^2 units while the sixth one is dimensionless.
19.42.5 Restrictions

This compute is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.43.2 Examples

compute 1 molecule gyration/shape/chunk pe

19.43.3 Description

Define a computation that calculates the eigenvalues of the gyration tensor and three shape parameters of multiple chunks of atoms. The computation includes all effects due to atoms passing through periodic boundaries.

The three computed shape parameters are the asphericity, b, the acylindricity, c, and the relative shape anisotropy, k:

\[
\begin{align*}
c &= l_z - 0.5(l_y + l_x) \\
b &= l_y - l_x \\
k &= \frac{3}{2} \frac{l_x^2 + l_y^2 + l_z^2}{(l_x + l_y + l_z)^2} - \frac{1}{2}
\end{align*}
\]

where \( l_x \leq l_y \leq l_z \) are the three eigenvalues of the gyration tensor. A general description of these parameters is provided in (Mattice) while an application to polymer systems can be found in (Theodorou). The asphericity is always
non-negative and zero only when the three principal moments are equal. This zero condition is met when the dis-
tribution of particles is spherically symmetric (hence the name asphericity) but also whenever the particle distribution
is symmetric with respect to the three coordinate axes, e.g., when the particles are distributed uniformly on a cube,
tetrahedron or other Platonic solid. The acylindricity is always non-negative and zero only when the two principal
moments are equal. This zero condition is met when the distribution of particles is cylindrically symmetric (hence the
name, acylindricity), but also whenever the particle distribution is symmetric with respect to the two coordinate axes,
e.g., when the particles are distributed uniformly on a regular prism. The relative shape anisotropy is bounded between
zero (if all points are spherically symmetric) and one (if all points lie on a line).

The tensor keyword must be specified in the compute gyration/chunk command.

**Note:** The coordinates of an atom contribute to the gyration tensor in “unwrapped” form, by using the image flags
associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the
Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can
reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

### 19.43.4 Output info

19.44 compute heat/flux command

19.44.1 Syntax

```
compute ID group-ID heat/flux ke-ID pe-ID stress-ID
```

- `ID, group-ID` are documented in `compute` command
- `heat/flux = style name of this compute command`
- `ke-ID = ID of a compute that calculates per-atom kinetic energy`
- `pe-ID = ID of a compute that calculates per-atom potential energy`
- `stress-ID = ID of a compute that calculates per-atom stress`

19.44.2 Examples

```
compute myFlux all heat/flux myKE myPE myStress
```

19.44.3 Description

Define a computation that calculates the heat flux vector based on contributions from atoms in the specified group. This can be used by itself to measure the heat flux through a set of atoms (e.g. a region between two thermostatted reservoirs held at different temperatures), or to calculate a thermal conductivity using the equilibrium Green-Kubo formalism.

For other non-equilibrium ways to compute a thermal conductivity, see the Howto kappa doc page. These include use of the fix thermal/conductivity command for the Muller-Plathe method. Or the fix heat command which can add or subtract heat from groups of atoms.

The compute takes three arguments which are IDs of other computes. One calculates per-atom kinetic energy (`ke-ID`), one calculates per-atom potential energy (`pe-ID`), and the third calculates per-atom stress (`stress-ID`).

**Note**: These other computes should provide values for all the atoms in the group this compute specifies. That means the other computes could use the same group as this compute, or they can just use group “all” (or any group whose atoms are superset of the atoms in this compute’s group). LAMMPS does not check for this.

In case of two-body interactions, the heat flux is defined as:

\[
J = \frac{1}{V} \left[ \sum_i e_i v_i - \sum_i S_i v_i \right]
\]

\[
= \frac{1}{V} \left[ \sum_i e_i v_i + \sum_{i<j} (F_{ij} \cdot v_j) r_{ij} \right]
\]

\[
= \frac{1}{V} \left[ \sum_i e_i v_i + \frac{1}{2} \sum_{i<j} (F_{ij} \cdot (v_i + v_j)) r_{ij} \right]
\]

\(e_i\) in the first term of the equation is the per-atom energy (potential and kinetic). This is calculated by the computes `ke-ID` and `pe-ID`. \(S_i\) in the second term is the per-atom stress tensor calculated by the compute `stress-ID`. See `compute stress/atom` and `compute centroid/stress/atom` for possible definitions of atomic stress \(S_i\) in the case of bonded and
many-body interactions. The tensor multiplies \( v_i \) as a 3x3 matrix-vector multiply to yield a vector. Note that as discussed below, the \( 1/V \) scaling factor in the equation for \( J \) is NOT included in the calculation performed by these computes; you need to add it for a volume appropriate to the atoms included in the calculation.

**Note:** The `compute pe/atom` and `compute stress/atom` commands have options for which terms to include in their calculation (pair, bond, etc). The heat flux calculation will thus include exactly the same terms. Normally you should use `compute stress/atom virial` or `compute centroid/stress/atom virial` so as not to include a kinetic energy term in the heat flux.

**Warning:** The compute `heat/flux` has been reported to produce unphysical values for angle, dihedral and improper contributions when used with `compute stress/atom`, as discussed in (Surblys) and (Boone). You are strongly advised to use `compute centroid/stress/atom`, which has been implemented specifically for such cases.

The Green-Kubo formulas relate the ensemble average of the auto-correlation of the heat flux \( J \) to the thermal conductivity \( \kappa \):

\[
\kappa = \frac{V}{k_B T^2} \int_0^\infty \langle J_x(0)J_x(t) \rangle \, dt = \frac{V}{3k_B T^2} \int_0^\infty \langle J(0) \cdot J(t) \rangle \, dt
\]

The heat flux can be output every so many timesteps (e.g. via the `thermo_style custom` command). Then as a post-processing operation, an auto-correlation can be performed, its integral estimated, and the Green-Kubo formula above evaluated.

The `fix ave/correlate` command can calculate the auto-correlation. The `trap()` function in the `variable` command can calculate the integral.

An example LAMMPS input script for solid Ar is appended below. The result should be: average conductivity ~0.29 in W/mK.

### 19.44.4 Output info

This compute calculates a global vector of length 6. The first 3 components are the \( x, y, z \) components of the full heat flux vector, i.e. \( (J_x, J_y, J_z) \). The next 3 components are the \( x, y, z \) components of just the convective portion of the flux, i.e. the first term in the equation for \( J \). Each component can be accessed by indices 1-6. These values can be used by any command that uses global vector values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The vector values calculated by this compute are “extensive”, meaning they scale with the number of atoms in the simulation. They can be divided by the appropriate volume to get a flux, which would then be an “intensive” value, meaning independent of the number of atoms in the simulation. Note that if the compute is “all”, then the appropriate volume to divide by is the simulation box volume. However, if a sub-group is used, it should be the volume containing those atoms.

The vector values will be in energy*velocity **units**. Once divided by a volume the units will be that of flux, namely energy/area/time **units**.
