This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

This compute also optionally calculates a global array, if one or more of the optional values are specified. The number of rows in the array = the number of chunks *Nchunk* as calculated by the specified *compute chunk/atom* command. The number of columns is the number of specified values (1 or more). These values can be accessed by any command that uses global array values from a compute as input. Again, see the *Howto output* doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”. The array values are “intensive”.

The scalar value will be in temperature *units*. The vector values will be in energy *units*. The array values will be in temperature *units* for the *temp* value, and in energy *units* for the *kecom* and *internal* values.

### 17.125.4 Restrictions

The *com* and *bias* keywords cannot be used together.

### 17.125.5 Related commands

*compute temp*, *fix ave/chunk temp*

### 17.125.6 Default

The option defaults are *com* no, *bias* no, *adof* = dimensionality of the system (2 or 3), and *cdof* = 0.0.

### 17.126 compute temp/com command

#### 17.126.1 Syntax

```
compute ID group-ID temp/com
```

- *ID, group-ID* are documented in *compute* command
- *temp/com* = style name of this compute command
17.126.2 Examples

```
compute 1 all temp/com
compute myTemp mobile temp/com
```

17.126.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out the center-of-mass velocity of the group. This is useful if the group is expected to have a non-zero net velocity for some reason. A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

After the center-of-mass velocity has been subtracted from each atom, the temperature is calculated by the formula KE = dim/2 N k T, where KE = total kinetic energy of the group of atoms (sum of 1/2 m v^2), dim = 2 or 3 = dimensionality of the simulation, N = number of atoms in the group, k = Boltzmann constant, and T = temperature.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that v^2 is replaced by vx*vy for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

The removal of the center-of-mass velocity by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` doc page for a discussion of different ways to compute temperature and perform thermostatting.

**Output info:**

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

compute temp

Default: none

17.127 compute temp/cs command

17.127.1 Syntax

compute ID group-ID temp/cs group1 group2

- ID, group-ID are documented in compute command
- temp/cs = style name of this compute command
- group1 = group-ID of either cores or shells
- group2 = group-ID of either shells or cores

17.127.2 Examples

compute oxygen_c-s all temp/cs O_core O_shell
compute core_shells all temp/cs cores shells

17.127.3 Description

Define a computation that calculates the temperature of a system based on the center-of-mass velocity of atom pairs that are bonded to each other. This compute is designed to be used with the adiabatic core/shell model of (Mitchell and Finchham). See the Howto coreshell doc page for an overview of the model as implemented in LAMMPS. Specifically, this compute enables correct temperature calculation and thermostatting of core/shell pairs where it is desirable for the internal degrees of freedom of the core/shell pairs to not be influenced by a thermostat. A compute of this style can be used by any command that computes a temperature via fix_modify e.g. fix temp/rescale, fix npt, etc.

Note that this compute does not require all ions to be polarized, hence defined as core/shell pairs. One can mix core/shell pairs and ions without a satellite particle if desired. The compute will consider the non-polarized ions according to the physical system.

For this compute, core and shell particles are specified by two respective group IDs, which can be defined using the group command. The number of atoms in the two groups must be the same and there should be one bond defined between a pair of atoms in the two groups. Non-polarized ions which might also be included in the treated system should not be included into either of these groups, they are taken into account by the group-ID (second argument) of the compute.

The temperature is calculated by the formula $KE = \frac{1}{2} N k T$, where $KE = \text{total kinetic energy of the group of atoms (sum of } \frac{1}{2} m v^2 \text{)}, dim = 2 \text{ or } 3 = \text{dimensionality of the simulation}, N = \text{number of atoms in the group}, k = \text{Boltzmann constant}, \text{and } T = \text{temperature}$. Note that the velocity of each core or shell atom used in the KE calculation is the velocity of the center-of-mass (COM) of the core/shell pair the atom is part of.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $vx^2$ for the $xy$ component, etc. The 6 components of the vector are ordered $xx, yy, zz, xy, xz, yz$. In contrast to the temperature, the velocity of each core or shell atom is taken individually.
The change this fix makes to core/shell atom velocities is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. This “bias” is the velocity of the atom relative to the COM velocity of the core/shell pair. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostatting of the remaining COM velocity will be performed, and the bias will be added back in. This means the thermostatting will effectively be performed on the core/shell pairs, instead of on the individual core and shell atoms. Thermostatting fixes that work in this way include fix nvt, fix temp/rescale, fix temp/berendsen, and fix langevin.

The internal energy of core/shell pairs can be calculated by the compute temp/chunk command, if chunks are defined as core/shell pairs. See the Howto coreshell doc page doc page for more discussion on how to do this.

Output info:

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

### 17.127.4 Restrictions

The number of core/shell pairs contributing to the temperature is assumed to be constant for the duration of the run. No fixes should be used which generate new molecules or atoms during a simulation.

### 17.128 compute temp/deform command

#### 17.128.1 Syntax

```
compute ID group-ID temp/deform
```

- ID, group-ID are documented in compute command
- temp/deform = style name of this compute command
17.128.2 Examples

compute myTemp all temp/deform

17.128.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out a streaming velocity induced by the simulation box changing size and/or shape, for example in a non-equilibrium MD (NEMD) simulation. The size/shape change is induced by use of the fix deform command. A compute of this style is created by the fix nvt/sllod command to compute the thermal temperature of atoms for thermostatting purposes. A compute of this style can also be used by any command that computes a temperature, e.g. thermo_modify, fix temp/rescale, fix npt, etc.

The deformation fix changes the box size and/or shape over time, so each atom in the simulation box can be thought of as having a “streaming” velocity. For example, if the box is being sheared in x, relative to y, then atoms at the bottom of the box (low y) have a small x velocity, while atoms at the top of the box (hi y) have a large x velocity. This position-dependent streaming velocity is subtracted from each atom’s actual velocity to yield a thermal velocity which is used to compute the temperature.

Note: Fix deform has an option for remapping either atom coordinates or velocities to the changing simulation box. When using this compute in conjunction with a deforming box, fix deform should NOT remap atom positions, but rather should let atoms respond to the changing box by adjusting their own velocities (or let fix deform remap the atom velocities, see it’s remap option). If fix deform does remap atom positions, then they appear to move with the box but their velocity is not changed, and thus they do NOT have the streaming velocity assumed by this compute. LAMMPS will warn you if fix deform is defined and its remap setting is not consistent with this compute.

After the streaming velocity has been subtracted from each atom, the temperature is calculated by the formula \( KE = \frac{\text{dim}}{2} N k T \), where \( KE \) = total kinetic energy of the group of atoms (sum of \( \frac{1}{2} m v^2 \)), \( \text{dim} = 2 \) or \( 3 \) = dimensionality of the simulation, \( N \) = number of atoms in the group, \( k \) = Boltzmann constant, and \( T \) = temperature. Note that \( v \) in the kinetic energy formula is the atom’s thermal velocity.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( vx*vy \) for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the dynamic option of the compute_modify command if this is not the case.

The removal of the box deformation velocity component by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include fix nvt, fix temp/rescale, fix temp/berendsen, and fix langevin.

Note: The temperature calculated by this compute is only accurate if the atoms are indeed moving with a stream velocity profile that matches the box deformation. If not, then the compute will subtract off an incorrect stream velocity, yielding a bogus thermal temperature. You should NOT assume that your atoms are streaming at the same rate the box is deforming. Rather, you should monitor their velocity profile, e.g. via the fix ave/chunk command. And you can compare the results of this compute to compute temp/profile, which actually calculates the stream profile before subtracting it. If the two computes do not give roughly the same temperature, then your atoms are not streaming consistent with the box deformation. See the fix deform command for more details on ways to get atoms to stream consistently with the box deformation.
This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as fix shake and fix rigid. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the extra option of the compute_modify command.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostatting.

**Output info:**

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

```
compute myTemp all temp/deform/eff
```

#### 17.129.3 Description

Define a computation that calculates the temperature of a group of nuclei and electrons in the electron force field model, after subtracting out a streaming velocity induced by the simulation box changing size and/or shape, for example in a non-equilibrium MD (NEMD) simulation. The size/shape change is induced by use of the fix deform command. A compute of this style is created by the fix nvt/sllod/eff command to compute the thermal temperature of atoms for thermostatting purposes. A compute of this style can also be used by any command that computes a temperature, e.g. thermo_modify, fix npt/eff, etc.

The calculation performed by this compute is exactly like that described by the compute temp/deform command, except that the formula for the temperature includes the radial electron velocity contributions, as discussed by the compute
temp/eff command. Note that only the translational degrees of freedom for each nuclei or electron are affected by the streaming velocity adjustment. The radial velocity component of the electrons is not affected.

**Output info:**

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature *units*. The vector values will be in energy *units*.

### 17.129.4 Restrictions

This compute is part of the USER-EFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

```

- ID, group-ID are documented in *compute* command
- temp/drude = style name of this compute command

#### 17.130.2 Examples

```
compute TDRUDE all temp/drude
```

#### 17.130.3 Description

Define a computation that calculates the temperatures of core-Drude pairs. This compute is designed to be used with the *thermalized Drude oscillator model*. Polarizable models in LAMMPS are described on the *Howto polarizable* doc page.

Drude oscillators consist of a core particle and a Drude particle connected by a harmonic bond, and the relative motion of these Drude oscillators is usually maintained cold by a specific thermostat that acts on the relative motion of the core-Drude particle pairs. Therefore, because LAMMPS considers Drude particles as normal atoms in its default temperature compute (*compute temp* command), the reduced temperature of the core-Drude particle pairs is not calculated correctly.

By contrast, this compute calculates the temperature of the cores using center-of-mass velocities of the core-Drude pairs, and the reduced temperature of the Drude particles using the relative velocities of the Drude particles with...
respect to their cores. Non-polarizable atoms are considered as cores. Their velocities contribute to the temperature of the cores.

**Output info:**
This compute calculates a global scalar (the temperature) and a global vector of length 6, which can be accessed by indices 1-6, whose components are

1. temperature of the centers of mass (temperature units)
2. temperature of the dipoles (temperature units)
3. number of degrees of freedom of the centers of mass
4. number of degrees of freedom of the dipoles
5. kinetic energy of the centers of mass (energy units)
6. kinetic energy of the dipoles (energy units)

These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

Both the scalar value and the first two values of the vector calculated by this compute are “intensive”. The other 4 vector values are “extensive”.

### 17.130.4 Restrictions

The number of degrees of freedom contributing to the temperature is assumed to be constant for the duration of the run unless the fix modify command sets the option dynamic yes.

### 17.130.5 Related commands

`fix drude, fix langevin/drude, fix drude/transform, pair_style thole, compute temp`

Default: none

### 17.131 compute temp/eff command

#### 17.131.1 Syntax

```
compute ID group-ID temp/eff
```

- ID, group-ID are documented in `compute` command
- temp/eff = style name of this compute command
17.131.2 Examples

```plaintext
compute 1 all temp/eff
compute myTemp mobile temp/eff
```

17.131.3 Description

Define a computation that calculates the temperature of a group of nuclei and electrons in the electron force field model. A compute of this style can be used by commands that compute a temperature, e.g. `thermo_modify`, `fix npt/ef`, etc.

The temperature is calculated by the formula \( KE = \frac{\text{dim}}{2} N k T \), where \( KE \) = total kinetic energy of the group of atoms (sum of \( \frac{1}{2} m v^2 \) for nuclei and sum of \( \frac{1}{2} (m v^2 + \frac{3}{4} m s^2) \) for electrons, where \( s \) includes the radial electron velocity contributions), \( \text{dim} = 2 \) or \( 3 \) = dimensionality of the simulation, \( N \) = number of atoms (only total number of nuclei in the eFF (see the `pair_eff` command) in the group, \( k \) = Boltzmann constant, and \( T \) = temperature. This expression is summed over all nuclear and electronic degrees of freedom, essentially by setting the kinetic contribution to the heat capacity to \( \frac{3}{2}k \) (where only nuclei contribute). This subtlety is valid for temperatures well below the Fermi temperature, which for densities two to five times the density of liquid H2 ranges from 86,000 to 170,000 K.

**Note:** For eFF models, in order to override the default temperature reported by LAMMPS in the thermodynamic quantities reported via the `thermo` command, the user should apply a `thermo_modify` command, as shown in the following example:

```plaintext
compute effTemp all temp/eff
thermo_style custom step etotal pe ke temp press
thermo_modify temp effTemp
```

A 6-component kinetic energy tensor is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( vx \times vy \) for the xy component, etc. For the eFF, again, the radial electronic velocities are also considered.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` doc page for a discussion of different ways to compute temperature and perform thermostating.

**Output info:**

The scalar value calculated by this compute is “intensive”, meaning it is independent of the number of atoms in the simulation. The vector values are “extensive”, meaning they scale with the number of atoms in the simulation.
17.131.4 Restrictions

This compute is part of the USER-EFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

17.131.5 Related commands

*compute temp/partial, compute temp/region, compute pressure*

Default: none

17.132 compute temp/partial command

17.132.1 Syntax

```latex
compute ID group-ID temp/partial xflag yflag zflag
```

- ID, group-ID are documented in *compute* command
- temp/partial = style name of this compute command
- xflag,yflag,zflag = 0/1 for whether to exclude/include this dimension

17.132.2 Examples

```latex
compute newT flow temp/partial 1 1 0
```

17.132.3 Description

Define a computation that calculates the temperature of a group of atoms, after excluding one or more velocity components. A compute of this style can be used by any command that computes a temperature, e.g. *thermo_modify, fix temp/rescale, fix npt*, etc.

The temperature is calculated by the formula $KE = \frac{dim}{2} N k T$, where $KE =$ total kinetic energy of the group of atoms (sum of $1/2 m v^2$), $dim =$ dimensionality of the simulation, $N =$ number of atoms in the group, $k =$ Boltzmann constant, and $T =$ temperature. The calculation of $KE$ excludes the $x$, $y$, or $z$ dimensions if $xflag$, $yflag$, or $zflag = 0$. The dim parameter is adjusted to give the correct number of degrees of freedom.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the calculation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $vx*vy$ for the $xy$ component, etc. The 6 components of the vector are ordered $xx, yy, zz, xy, xz, yz$.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the *dynamic* option of the *compute_modify* command if this is not the case.

The removal of velocity components by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include *fix nvt, fix temp/rescale, fix temp/berendsen, and fix langevin*. 
This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` doc page for a discussion of different ways to compute temperature and perform thermostating.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

**Output info:**

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

| compute myTemp flow temp/profile 1 1 1 x 10 out bin |
| compute myTemp flow temp/profile 0 1 1 xyz 20 20 20 |

### 17.133.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out a spatially-averaged center-of-mass velocity field, before computing the kinetic energy. This can be useful for thermostating a collection of atoms undergoing a complex flow, e.g. via a profile-unbiased thermostat (PUT) as described in (Evans). A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

The `xflag`, `yflag`, `zflag` settings determine which components of average velocity are subtracted out.

The `binstyle` setting and its `Nx`, `Ny`, `Nz` arguments determine how bins are setup to perform spatial averaging. “Bins” can be 1d slabs, 2d pencils, or 3d bricks depending on which `binstyle` is used. The simulation box is partitioned conceptually into \( Nx \) by \( Ny \) by \( Nz \) bins. Depending on the `binstyle`, you may only specify one or two of these values; the others are effectively set to 1 (no binning in that dimension). For non-orthogonal (triclinic) simulation boxes, the bins are “tilted” slabs or pencils or bricks that are parallel to the tilted faces of the box. See the `region prism` command for a discussion of the geometry of tilted boxes in LAMMPS.

When a temperature is computed, the center-of-mass velocity for the set of atoms that are both in the compute group and in the same spatial bin is calculated. This bias velocity is then subtracted from the velocities of individual atoms in the bin to yield a thermal velocity for each atom. Note that if there is only one atom in the bin, its thermal velocity will thus be 0.0.

After the spatially-averaged velocity field has been subtracted from each atom, the temperature is calculated by the formula \( KE = (\dim * N - \dim * Nx * Ny * Nz) \; k \; T/2 \), where \( KE \) = total kinetic energy of the group of atoms (sum of 1/2 \( m \; v^2 \)), \( \dim = 2 \) or 3 = dimensionality of the simulation, \( N \) = number of atoms in the group, \( k \) = Boltzmann constant, and \( T \) = temperature. The \( \dim * Nx * Ny * Nz \) term are degrees of freedom subtracted to adjust for the removal of the center-of-mass velocity in each of \( Nx * Ny * Nz \) bins, as discussed in the (Evans) paper.

If the `out` keyword is used with a `tensor` value, which is the default, a kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( vx * vy \) for the xy component, etc. The 6 components of the vector are ordered `xx`, `yy`, `zz`, `xy`, `xz`, `yz`.

If the `out` keyword is used with a `bin` value, the count of atoms and computed temperature for each bin are stored for output, as an array of values, as described below. The temperature of each bin is calculated as described above,
where the bias velocity is subtracted and only the remaining thermal velocity of atoms in the bin contributes to the temperature. See the note below for how the temperature is normalized by the degrees-of-freedom of atoms in the bin.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

The removal of the spatially-averaged velocity field by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

**Note:** When using the `out` keyword with a value of `bin`, the calculated temperature for each bin does not include the degrees-of-freedom adjustment described in the preceding paragraph, for fixes that constrain molecular motion. It does include the adjustment due to the `extra` option, which is applied to each bin.

See the `Howto thermostat` doc page for a discussion of different ways to compute temperature and perform thermostatting. Using this compute in conjunction with a thermostatting fix, as explained there, will effectively implement a profile-unbiased thermostat (PUT), as described in (Evans).

**Output info:**

This compute calculates a global scalar (the temperature). Depending on the setting of the `out` keyword, it also calculates a global vector or array. For `out = tensor`, it calculates a vector of length 6 (KE tensor), which can be accessed by indices 1-6. For `out = bin` it calculates a global array which has 2 columns and N rows, where N is the number of bins. The first column contains the number of atoms in that bin. The second contains the temperature of that bin, calculated as described above. The ordering of rows in the array is as follows. Bins in x vary fastest, then y, then z. Thus for a 10x10x10 3d array of bins, there will be 1000 rows. The bin with indices ix,iy,iz = 2,3,4 would map to row M = (iz-1)*10*10 + (iy-1)*10 + ix = 322, where the rows are numbered from 1 to 1000 and the bin indices are numbered from 1 to 10 in each dimension.

These values can be used by any command that uses global scalar or vector or array values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”. The array values are “intensive”.

The scalar value will be in temperature units. The vector values will be in energy units. The first column of array values are counts; the values in the second column will be in temperature units.

### 17.133.4 Restrictions

You should not use too large a velocity-binning grid, especially in 3d. In the current implementation, the binned velocity averages are summed across all processors, so this will be inefficient if the grid is too large, and the operation is performed every timestep, as it will be for most thermostats.
17.133.5 Related commands

`compute temp`, `compute temp/ramp`, `compute temp/deform`, `compute pressure`

17.133.6 Default

The option default is `out = tensor`.

17.134 compute temp/ramp command

17.134.1 Syntax

```
compute ID group-ID temp/ramp vdim vlo vhi dim clo chi keyword value ...
```

- ID, group-ID are documented in `compute` command
- `temp/ramp` = style name of this compute command
- `vdim` = `vx` or `vy` or `vz`
- `vlo, vhi` = subtract velocities between `vlo` and `vhi` (velocity units)
- `dim` = `x` or `y` or `z`
- `clo, chi` = lower and upper bound of domain to subtract from (distance units)
- zero or more keyword/value pairs may be appended
- `keyword = units`
  
  `units value = lattice` or `box`

17.134.2 Examples

```
compute 2nd middle temp/ramp vx 0 8 y 2 12 units lattice
```

17.134.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out an ramped velocity profile before computing the kinetic energy. A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

The meaning of the arguments for this command which define the velocity ramp are the same as for the `velocity ramp` command which was presumably used to impose the velocity.

After the ramp velocity has been subtracted from the specified dimension for each atom, the temperature is calculated by the formula \( KE = \frac{\text{dim}/2}{N \ k \ T} \), where \( KE = \) total kinetic energy of the group of atoms (sum of \( 1/2 \ m \ v^2 \)), \( \text{dim} = 2 \) or \( 3 \) = dimensionality of the simulation, \( N = \) number of atoms in the group, \( k = \) Boltzmann constant, and \( T = \) temperature.
The `units` keyword determines the meaning of the distance units used for coordinates \((c1,c2)\) and velocities \((vlo,vhi)\). A `box` value selects standard distance units as defined by the `units` command, e.g. Angstroms for units = real or metal. A `lattice` value means the distance units are in lattice spacings; e.g. velocity = lattice spacings / \(\tau\). The `lattice` command must have been previously used to define the lattice spacing.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \(v^2\) is replaced by \(v_x v_y\) for the \(xy\) component, etc. The 6 components of the vector are ordered \(xx, yy, zz, xy, xz, yz\).

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

The removal of the ramped velocity component by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` doc page for a discussion of different ways to compute temperature and perform thermostatting.

**Output info:**

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”. The scalar value will be in temperature `units`. The vector values will be in energy `units`.

1530 Chapter 17. Computes
17.135 compute temp/region command

17.135.1 Syntax

```
compute ID group-ID temp/region region-ID
```

- ID, group-ID are documented in `compute` command
- temp/region = style name of this compute command
- region-ID = ID of region to use for choosing atoms

17.135.2 Examples

```
compute mine flow temp/region boundary
```

17.135.3 Description

Define a computation that calculates the temperature of a group of atoms in a geometric region. This can be useful for thermostatting one portion of the simulation box. E.g. a McDLT simulation where one side is cooled, and the other side is heated. A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, etc.

Note that a region-style temperature can be used to thermostat with `fix temp/rescale` or `fix langevin`, but should probably not be used with Nose/Hoover style fixes (`fix nvt`, `fix npt`, or `fix nph`), if the degrees-of-freedom included in the computed T varies with time.

The temperature is calculated by the formula \( KE = \frac{dim}{2} N k T \), where \( KE \) = total kinetic energy of the group of atoms (sum of \( 1/2 m v^2 \)), \( dim = 2 \) or \( 3 \) = dimensionality of the simulation, \( N \) = number of atoms in both the group and region, \( k \) = Boltzmann constant, and \( T \) = temperature.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( v_x v_y \) for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is calculated each time the temperature is evaluated since it is assumed atoms can enter/leave the region. Thus there is no need to use the `dynamic` option of the `compute_modify` command for this compute style.

The removal of atoms outside the region by this fix is essentially computing the temperature after a “bias” has been removed, which in this case is the velocity of any atoms outside the region. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`. This means that when this compute is used to calculate the temperature for any of the thermostatting fixes via the `fix modify temp` command, the thermostat will operate only on atoms that are currently in the geometric region.

Unlike other compute styles that calculate temperature, this compute does not subtract out degrees-of-freedom due to fixes that constrain motion, such as `fix shake` and `fix rigid`. This is because those degrees of freedom (e.g. a constrained bond) could apply to sets of atoms that straddle the region boundary, and hence the concept is somewhat ill-defined. If needed the number of subtracted degrees-of-freedom can be set explicitly using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` doc page for a discussion of different ways to compute temperature and perform thermostatting.
Output info:

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. 17.138.1 Syntax

    compute ID group-ID temp/sphere keyword value ...

- ID, group-ID are documented in compute command
- temp/sphere = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = bias or dof
  bias value = bias-ID
  bias-ID = ID of a temperature compute that removes a velocity bias
dof value = all or rotate
  all = compute temperature of translational and rotational degrees of freedom
  rotate = compute temperature of just rotational degrees of freedom
17.138.2 Examples

\begin{verbatim}
compute 1 all temp/sphere
compute myTemp mobile temp/sphere bias tempCOM
compute myTemp mobile temp/sphere dof rotate
\end{verbatim}

17.138.3 Description

Define a computation that calculates the temperature of a group of spherical particles, including a contribution from both their translational and rotational kinetic energy. This differs from the usual `compute temp` command, which assumes point particles with only translational kinetic energy.

Both point and finite-size particles can be included in the group. Point particles do not rotate, so they have only 3 translational degrees of freedom. For 3d spherical particles, each has 6 degrees of freedom (3 translational, 3 rotational). For 2d spherical particles, each has 3 degrees of freedom (2 translational, 1 rotational).

**Note:** This choice for degrees of freedom (dof) assumes that all finite-size spherical particles in your model will freely rotate, sampling all their rotational dof. It is possible to use a combination of interaction potentials and fixes that induce no torque or otherwise constrain some of all of your particles so that this is not the case. Then there are less dof and you should use the `compute_modify extra` command to adjust the dof accordingly.

The translational kinetic energy is computed the same as is described by the `compute temp` command. The rotational kinetic energy is computed as $1/2 \ I \ w^2$, where $I$ is the moment of inertia for a sphere and $w$ is the particle’s angular velocity.

**Note:** For 2d models, particles are treated as spheres, not disks, meaning their moment of inertia will be the same as in 3d.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formulas, except that $v^2$ and $w^2$ are replaced by $vx*vy$ and $wx*wy$ for the xy component. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out translational degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostating.

The keyword/value option pairs are used in the following ways.

For the `bias` keyword, `bias-ID` refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This allows compute temp/sphere to compute its thermal temperature after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile. Thermostats that use this compute will work with this bias term. See the doc pages for individual computes that calculate a temperature and the doc pages for fixes that perform thermostating for more details.

For the `dof` keyword, a setting of `all` calculates a temperature that includes both translational and rotational degrees of freedom. A setting of `rotate` calculates a temperature that includes only rotational degrees of freedom.
Output info:
This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

17.138.4 Restrictions
This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the atom_style sphere command.

All particles in the group must be finite-size spheres, or point particles with radius = 0.0.

compute 1 all ti lj/cut 1*3 v_lj v_dlj coul/long * v_c v_dc kspace * v_ks v_dks
```

17.140.3 Description

Define a computation that calculates the derivative of the interaction potential with respect to \( \lambda \), the coupling parameter used in a thermodynamic integration. This derivative can be used to infer a free energy difference resulting from an alchemical simulation, as described in Eike.

 Typically this compute will be used in conjunction with the `fix adapt` command which can perform alchemical transformations by adjusting the strength of an interaction potential as a simulation runs, as defined by one or more `pair_style` or `kspace_style` commands. This scaling is done via a prefactor on the energy, forces, virial calculated by the pair or K-Space style. The prefactor is often a function of a \( \lambda \) parameter which may be adjusted from 0 to 1 (or vice versa) over the course of a run. The time-dependent adjustment is what the `fix adapt` command does.

Assume that the unscaled energy of a pair_style or kspace_style is given by \( U \). Then the scaled energy is

\[
U_s = f(\lambda) U
\]

where \( f() \) is some function of \( \lambda \). What this compute calculates is

\[
\frac{dU_s}{d(\lambda)} = \frac{U df(\lambda)}{d\lambda} = \frac{U_s}{f(\lambda)} df(\lambda) / d\lambda
\]

which is the derivative of the system’s scaled potential energy \( U_s \) with respect to \( \lambda \).

To perform this calculation, you provide one or more atom types as `attype`. `Attype` can be specified in one of two ways. An explicit numeric values can be used, as in the first example above. Or a wildcard asterisk can be used in place of or in conjunction with the `attype` argument to select multiple atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If \( N \) = the number of atom types, then an asterisk with no numeric values means all types from 1 to \( N \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( N \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive).

You also specify two functions, as `equal-style variables`. The first is specified as `v_name1`, where `name1` is the name of the variable, and is \( f(\lambda) \) in the notation above. The second is specified as `v_name2`, where `name2` is the name of the variable, and is \( df(\lambda) / d\lambda \) in the notation above. I.e. it is the analytic derivative of \( f() \) with respect to \( \lambda \). Note that the `name1` variable is also typically given as an argument to the `fix adapt` command.

An alchemical simulation may use several pair potentials together, invoked via the `pair_style hybrid` or `hybrid/overlay` command. The total \( dU_s/d\lambda \) for the overall system is calculated as the sum of each contributing term as listed by the keywords in the compute ti command. Individual pair potentials can be listed, which will be sub-styles in the hybrid case. You can also include a K-space term via the `kspace` keyword. You can also include a pairwise long-range tail correction to the energy via the `tail` keyword.

For each term you can specify a different (or the same) scale factor by the two variables that you list. Again, these will typically correspond to the scale factors applied to these various potentials and the K-Space contribution via the `fix adapt` command.

More details about the exact functional forms for the computation of \( dU/d\lambda \) can be found in the paper by Eike.

Output info:

This compute calculates a global scalar, namely \( dU_s/d\lambda \). This value can be used by any command that uses a global scalar value from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.
The scalar value calculated by this compute is “extensive”.
The scalar value will be in energy units.

17.140.4 Restrictions

fix adapt
Default: none

17.141 compute torque/chunk command

17.141.1 Syntax

```plaintext
compute ID group-ID torque/chunk chunkID
```

- ID, group-ID are documented in `compute` command
- torque/chunk = style name of this compute command
- chunkID = ID of `compute chunk/atom` command

17.141.2 Examples

```plaintext
compute 1 fluid torque/chunk molchunk
```

17.141.3 Description

Define a computation that calculates the torque on multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the 3 components of the torque vector for each chunk, due to the forces on the individual atoms in the chunk around the center-of-mass of the chunk. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.
Note: The coordinates of an atom contribute to the chunk’s torque in “unwrapped” form, by using the image flags associated with each atom. See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the set image command.

The simplest way to output the results of the compute torque/chunk calculation to a file is to use the fix ave/time command, for example:

```
calculate ccl all chunk/atom molecule
calculate myChunk all torque/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

Output info:

This compute calculates a global array where the number of rows = the number of chunks $N_{chunk}$ as calculated by the specified compute chunk/atom command. The number of columns = 3 for the 3 xyz components of the torque for each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in force-distance units.

- vacf = style name of this compute command
17.142.2 Examples

```
compute 1 all vacf
compute 1 upper vacf
```

17.142.3 Description

Define a computation that calculates the velocity auto-correlation function (VACF), averaged over a group of atoms. Each atom’s contribution to the VACF is its current velocity vector dotted into its initial velocity vector at the time the compute was specified.

A vector of four quantities is calculated by this compute. The first 3 elements of the vector are vx * vx0 (and similarly for the y and z components), summed and averaged over atoms in the group. Vx is the current x-component of velocity for the atom, vx0 is the initial x-component of velocity for the atom. The fourth element of the vector is the total VACF, i.e. (vx*vx0 + vy*vy0 + vz*vz0), summed and averaged over atoms in the group.

The integral of the VACF versus time is proportional to the diffusion coefficient of the diffusing atoms. This can be computed in the following manner, using the `variable trap()` function:

```
compute 2 all vacf
fix 5 all vector 1 c_2[4]
variable diff equal dt*trap(f_5)
thermo_style custom step v_diff
```

**Note:** If you want the quantities calculated by this compute to be continuous when running from a restart file, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with time=0 atom velocities from the restart file.

**Output info:**

This compute calculates a global vector of length 4, which can be accessed by indices 1-4 by any command that uses global vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The vector values will be in velocity^2 units.

17.143 compute vcm/chunk command

17.143.1 Syntax

\texttt{compute ID group-ID vcm/chunk chunkID}

- ID, group-ID are documented in \textit{compute} command
- vcm/chunk = style name of this compute command
- chunkID = ID of \textit{compute chunk/atom} command

17.143.2 Examples

\texttt{compute 1 fluid vcm/chunk molchunk}

17.143.3 Description

Define a computation that calculates the center-of-mass velocity for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a \textit{compute chunk/atom} command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the \textit{compute chunk/atom} and \textit{Howto chunk} doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the x,y,z components of the center-of-mass velocity for each chunk. This is done by summing mass*velocity for each atom in the chunk and dividing the sum by the total mass of the chunk.

Note that only atoms in the specified group contribute to the calculation. The \textit{compute chunk/atom} command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

The simplest way to output the results of the compute vcm/chunk calculation to a file is to use the \textit{fix ave/time} command, for example:

\begin{verbatim}
compute ccl all chunk/atom molecule
compute myChunk all vcm/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
\end{verbatim}

Output info:

This compute calculates a global array where the number of rows = the number of chunks $N_{chunk}$ as calculated by the specified \textit{compute chunk/atom} command. The number of columns = 3 for the x,y,z center-of-mass velocity coordinates of each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the \textit{Howto output} doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in velocity units.

17.144 compute viscosity/cos command

17.144.1 Syntax

compute ID group-ID viscosity/cos

• ID, group-ID are documented in compute command

• viscosity/cos = style name of this compute command

17.144.2 Examples

compute cos all viscosity/cos
variable V equal c_cos[7]
variable A equal 0.02E-5
variable density equal density
variable lz equal lz
variable reciprocalViscosity equal v_V/A/v_density*39.4784/v_lz/v_lz*100

17.144.3 Description

Define a computation that calculates the velocity amplitude of a group of atoms with a cosine-shaped velocity profile and the temperature of them after subtracting out the velocity profile before computing the kinetic energy. A compute of this style can be used by any command that computes a temperature, e.g. thermo_modify, fix npt, etc.

This command together with fix accelerate/cos enables viscosity calculation with periodic perturbation method, as described by Hess. An acceleration along the x-direction is applied to the simulation system by using fix accelerate/cos command. The acceleration is a periodic function along the z-direction:

\[ a_x(z) = A \cos \left( \frac{2\pi z}{l_z} \right) \]

where \( A \) is the acceleration amplitude, \( l_z \) is the z-length of the simulation box. At steady state, the acceleration generates a velocity profile:

\[ v_x(z) = V \cos \left( \frac{2\pi z}{l_z} \right) \]

The generated velocity amplitude \( V \) is related to the shear viscosity \( \eta \) by:

\[ V = \frac{A \rho}{\eta} \left( \frac{l_z}{2\pi} \right)^2 \]

and it can be obtained from ensemble average of the velocity profile:

\[ V = \frac{\sum_i 2m_i v_i,x \cos \left( \frac{2\pi z_i}{l_z} \right)}{\sum_i m_i} \]
where $m_i$, $v_{i,x}$ and $z_i$ are the mass, x-component velocity and z coordinate of a particle.

After the cosine-shaped collective velocity in $x$ direction has been subtracted for each atom, the temperature is calculated by the formula $KE = \frac{dim}{2} N k T$, where $KE =$ total kinetic energy of the group of atoms (sum of $\frac{1}{2} m v^2$), $dim = 2$ or $3 =$ dimensionality of the simulation, $N =$ number of atoms in the group, $k =$ Boltzmann constant, and $T =$ temperature.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $v_x v_y$ for the xy component, etc. The 6 components of the vector are ordered $xx$, $yy$, $zz$, $xy$, $xz$, $yz$.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the dynamic option of the compute_modify command if this is not the case. However, in order to get meaningful result, the group ID of this compute should be all.

The removal of the cosine-shaped velocity component by this command is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include fix nvt, fix temp/rescale, fix temp/berendsen, and fix langevin.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as fix shake and fix rigid. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the extra option of the compute_modify command.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostatting.

Output info:

This compute calculates a global scalar (the temperature) and a global vector of length 7, which can be accessed by indices 1-7. The first 6 elements of the vector are the KE tensor, and the 7-th is the cosine-shaped velocity amplitude $V$, which can be used to calculate the reciprocal viscosity, as shown in the example. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The first 6 elements of vector values are “extensive”, and the 7-th element of vector values is “intensive”.

The scalar value will be in temperature units. The first 6 elements of vector values will be in energy units. The 7-th element of vector value will be in velocity units.

17.144.4 Restrictions

This command is only available when LAMMPS was built with the USER-MISC package. Since this compute depends on fix accelerate/cos which can only work for 3d systems, it cannot be used for 2d systems.

compute 3b precipitate voronoi/atom radius v_r
compute 4 solute voronoi/atom only_group
compute 5 defects voronoi/atom occupation
compute 6 all voronoi/atom neighbors yes
```

17.145.3 Description

Define a computation that calculates the Voronoi tessellation of the atoms in the simulation box. The tessellation is calculated using all atoms in the simulation, but non-zero values are only stored for atoms in the group.

By default two per-atom quantities are calculated by this compute. The first is the volume of the Voronoi cell around each atom. Any point in an atom’s Voronoi cell is closer to that atom than any other. The second is the number of faces of the Voronoi cell. This is equal to the number of nearest neighbors of the central atom, plus any exterior faces (see note below). If the `peratom` keyword is set to “no”, the per-atom quantities are still calculated, but they are not accessible.

If the `only_group` keyword is specified the tessellation is performed only with respect to the atoms contained in the compute group. This is equivalent to deleting all atoms not contained in the group prior to evaluating the tessellation.

If the `surface` keyword is specified a third quantity per atom is computed: the Voronoi cell surface of the given atom. `surface` takes a group ID as an argument. If a group other than `all` is specified, only the Voronoi cell facets facing a neighbor atom from the specified group are counted towards the surface area.

In the example above, a precipitate embedded in a matrix, only atoms at the surface of the precipitate will have non-zero surface area, and only the outward facing facets of the Voronoi cells are counted (the hull of the precipitate). The total surface area of the precipitate can be obtained by running a “reduce sum” compute on c_2[3]

If the `radius` keyword is specified with an atom style variable as the argument, a poly-disperse Voronoi tessellation is performed. Examples for radius variables are

```
variable r1 atom (type==1)*0.1+(type==2)*0.4
compute radius all property/atom radius
variable r2 atom c_radius
```

Here v_r1 specifies a per-type radius of 0.1 units for type 1 atoms and 0.4 units for type 2 atoms, and v_r2 accesses the radius property present in atom_style sphere for granular models.

The `edge_histo` keyword activates the compilation of a histogram of number of edges on the faces of the Voronoi cells in the compute group. The argument `maxedge` of the this keyword is the largest number of edges on a single Voronoi cell face expected to occur in the sample. This keyword adds the generation of a global vector with `maxedge+1` entries. The last entry in the vector contains the number of faces with more than `maxedge` edges. Since the polygon with the smallest amount of edges is a triangle, entries 1 and 2 of the vector will always be zero.

The `edge_threshold` and `face_threshold` keywords allow the suppression of edges below a given minimum length and faces below a given minimum area. Ultra short edges and ultra small faces can occur as artifacts of the Voronoi tessellation. These keywords will affect the neighbor count and edge histogram outputs.

If the `occupation` keyword is specified the tessellation is only performed for the first invocation of the compute and then stored. For all following invocations of the compute the number of atoms in each Voronoi cell in the stored tessellation is counted. In this mode the compute returns a per-atom array with 2 columns. The first column is the number of atoms currently in the Voronoi volume defined by this atom at the time of the first invocation of the compute (note that the atom may have moved significantly). The second column contains the total number of atoms sharing
the Voronoi cell of the stored tessellation at the location of the current atom. Numbers in column one can be any positive integer including zero, while column two values will always be greater than zero. Column one data can be used to locate vacancies (the coordinates are given by the atom coordinates at the time step when the compute was first invoked), while column two data can be used to identify interstitial atoms.

If the `neighbors` value is set to yes, then this compute creates a local array with 3 columns. There is one row for each face of each Voronoi cell. The 3 columns are the atom ID of the atom that owns the cell, the atom ID of the atom in the neighboring cell (or zero if the face is external), and the area of the face. The array can be accessed by any command that uses local values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options. More specifically, the array can be accessed by a `dump local` command to write a file containing all the Voronoi neighbors in a system:

```
compute 6 all voronoi/atom neighbors yes
```

If the `face_threshold` keyword is used, then only faces with areas greater than the threshold are stored.

The Voronoi calculation is performed by the freely available Voro++ package, written by Chris Rycroft at UC Berkeley and LBL, which must be installed on your system when building LAMMPS for use with this compute. See instructions on obtaining and installing the Voro++ software in the src/VORONOI/README file.

**Note:** The calculation of Voronoi volumes is performed by each processor for the atoms it owns, and includes the effect of ghost atoms stored by the processor. This assumes that the Voronoi cells of owned atoms are not affected by atoms beyond the ghost atom cut-off distance. This is usually a good assumption for liquid and solid systems, but may lead to underestimation of Voronoi volumes in low density systems. By default, the set of ghost atoms stored by each processor is determined by the cutoff used for pair_style interactions. The cutoff can be set explicitly via the `comm_modify cutoff` command. The Voronoi cells for atoms adjacent to empty regions will extend into those regions up to the communication cutoff in x, y, or z. In that situation, an exterior face is created at the cutoff distance normal to the x, y, or z direction. For triclinic systems, the exterior face is parallel to the corresponding reciprocal lattice vector.

**Note:** The Voro++ package performs its calculation in 3d. This will still work for a 2d LAMMPS simulation, provided all the atoms have the same z coordinate. The Voronoi cell of each atom will be a columnar polyhedron with constant cross-sectional area along the z direction and two exterior faces at the top and bottom of the simulation box. If the atoms do not all have the same z coordinate, then the columnar cells will be accordingly distorted. The cross-sectional area of each Voronoi cell can be obtained by dividing its volume by the z extent of the simulation box. Note that you define the z extent of the simulation box for 2d simulations when using the `create_box` or `read_data` commands.

**Output info:**

By default, this compute calculates a per-atom array with 2 columns. In regular dynamic tessellation mode the first column is the Voronoi volume, the second is the neighbor count, as described above (read above for the output data in case the `occupation` keyword is specified). These values can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options. If the `peratom` keyword is set to “no”, the per-atom array is still created, but it is not accessible.

If the `edge_histo` keyword is used, then this compute generates a global vector of length `maxedge+1`, containing a histogram of the number of edges per face.

If the `neighbors` value is set to yes, then this compute calculates a local array with 3 columns. There is one row for each face of each Voronoi cell.

**Note:** Some LAMMPS commands such as the `compute reduce` command can accept either a per-atom or local quantity. If this compute produces both quantities, the command may access the per-atom quantity, even if you want
to access the local quantity. This effect can be eliminated by using the \textit{peratom} keyword to turn off the production of the per-atom quantities. For the default value \textit{yes} both quantities are produced. For the value \textit{no}, only the local array is produced.

The Voronoi cell volume will be in distance \textit{units} cubed. The Voronoi face area will be in distance \textit{units} squared.

\subsection*{17.145.4 Restrictions}

This compute is part of the VORONOI package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

It also requires you have a copy of the Voro++ library built and installed on your system. See instructions on obtaining and installing the Voro++ software in the src/VORONOI/README file.

\subsection*{17.145.5 Related commands}

```

17.146.3 Description

Define a computation that calculates x-ray diffraction intensity as described in (Coleman) on a mesh of reciprocal lattice nodes defined by the entire simulation domain (or manually) using a simulated radiation of wavelength lambda.

The x-ray diffraction intensity, I, at each reciprocal lattice point, k, is computed from the structure factor, F, using the equations:

\[
I = Lp(\theta) \frac{F^* F}{N} \\
F(k) = \sum_{j=1}^{N} f_j(\theta) \exp(2\pi i k \cdot r_j) \\
Lp(\theta) = \frac{1 + \cos^2(2\theta)}{\cos(\theta) \sin^2(\theta)} \\
\sin(\theta) = \frac{|k|}{\lambda}
\]

Here, K is the location of the reciprocal lattice node, \( r_j \) is the position of each atom, \( f_j \) are atomic scattering factors, \( Lp \) is the Lorentz-polarization factor, and \( \theta \) is the scattering angle of diffraction. The Lorentz-polarization factor can be turned off using the optional LP keyword.

Diffraction intensities are calculated on a three-dimensional mesh of reciprocal lattice nodes. The mesh spacing is defined either (a) by the entire simulation domain or (b) manually using selected values as shown in the 2D diagram below.

For a mesh defined by the simulation domain, a rectilinear grid is constructed with spacing \( c \times \text{inv(A)} \) along each reciprocal lattice axis. Where A are the vectors corresponding to the edges of the simulation cell. If one or two directions has non-periodic boundary conditions, then the spacing in these directions is defined from the average of the (inversed) box lengths with periodic boundary conditions. Meshes defined by the simulation domain must contain at least one periodic boundary.

If the manual flag is included, the mesh of reciprocal lattice nodes will defined using the c values for the spacing along each reciprocal lattice axis. Note that manual mapping of the reciprocal space mesh is good for comparing diffraction results from multiple simulations; however it can reduce the likelihood that Bragg reflections will be satisfied unless small spacing parameters (< 0.05 Ångström^(-1)) are implemented. Meshes with manual spacing do not require a periodic boundary.

The limits of the reciprocal lattice mesh are determined by range of scattering angles explored. The 2Theta parameters allows the user to reduce the scattering angle range to only the region of interest which reduces the cost of the computation.

The atomic scattering factors, \( f_j \), accounts for the reduction in diffraction intensity due to Compton scattering. Compute xrd uses analytical approximations of the atomic scattering factors that vary for each atom type (type1 type2 ...
typeN) and angle of diffraction. The analytic approximation is computed using the formula (Colliex):

\[ f_j \left( \frac{\sin(\theta)}{\lambda} \right) = \sum_i a_i \exp \left( -b_i \frac{\sin^2(\theta)}{\lambda^2} \right) + c \]

Coefficients parameterized by (Peng) are assigned for each atom type designating the chemical symbol and charge of each atom type. Valid chemical symbols for compute xrd are:

18.1 pair_style adp command

18.2 pair_style adp/omp command

18.2.1 Syntax

```
pair_style adp
```

18.2.2 Examples

```
pair_style adp
pair_coeff * * Ta.adp Ta
pair_coeff * * ../potentials/AlCu.adp Al Al Cu
```

18.2.3 Description

Style adp computes pairwise interactions for metals and metal alloys using the angular dependent potential (ADP) of (Mishin), which is a generalization of the embedded atom method (EAM) potential. The LAMMPS implementation is discussed in (Singh). The total energy $E_i$ of an atom $I$ is given by

$$
E_i = F_\alpha \left( \sum_{j \neq i} \rho_\beta(r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha\beta}(r_{ij}) + \frac{1}{2} \sum_s (\mu_i^s)^2 + \frac{1}{2} \sum_{s,t} (\lambda_i^{st})^2 - \frac{1}{6} \nu_i^2
$$

$$
\mu_i^s = \sum_{j \neq i} u_{\alpha\beta}(r_{ij}) r_{ij}^s
$$

$$
\lambda_i^{st} = \sum_{j \neq i} w_{\alpha\beta}(r_{ij}) r_{ij}^s r_{ij}^t
$$

$$
\nu_i = \sum_s \lambda_i^{ss}
$$

where $F$ is the embedding energy which is a function of the atomic electron density $\rho$, $\phi$ is a pair potential interaction, $\alpha$ and $\beta$ are the element types of atoms $I$ and $J$, and $s$ and $t = 1, 2, 3$ and refer to the cartesian coordinates. The $\mu$ and $\lambda$ terms represent the dipole and quadruple distortions of the local atomic environment which extend the original EAM framework by introducing angular forces.
Note that unlike for other potentials, cutoffs for ADP potentials are not set in the pair_style or pair_coeff command; they are specified in the ADP potential files themselves. Likewise, the ADP potential files list atomic masses; thus you do not need to use the mass command to specify them.

**ADP potentials are available from:**

- The NIST WWW site at [http://www.ctcms.nist.gov/potentials](http://www.ctcms.nist.gov/potentials). Note that ADP potentials obtained from NIST must be converted into the extended DYNAMO setfl format discussed below.
- The OpenKIM Project at [https://openkim.org/browse/models/by-type](https://openkim.org/browse/models/by-type) provides ADP potentials that can be used directly in LAMMPS with the kim_commands interface.

Only a single pair_coeff command is used with the adp style which specifies an extended DYNAMO setfl file, which contains information for \( M \) elements. These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:

- filename
- \( N \) element names = mapping of extended setfl elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, the potentials/AlCu.adp file, included in the potentials directory of the LAMMPS distribution, is an extended setfl file which has tabulated ADP values for \( w \) elements and their alloy interactions: Cu and Al. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Al, and the fourth to be Cu, you would use the following pair_coeff command:

```
pair_coeff ** AlCu.adp Al Al Al Cu
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three Al arguments map LAMMPS atom types 1,2,3 to the Al element in the extended setfl file. The final Cu argument maps LAMMPS atom type 4 to the Al element in the extended setfl file. Note that there is no requirement that your simulation use all the elements specified by the extended setfl file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an adp potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Adp files in the potentials directory of the LAMMPS distribution have an “.adp” suffix. A DYNAMO setfl file extended for ADP is formatted as follows. Basically it is the standard setfl format with additional tabulated functions \( u \) and \( w \) added to the file after the tabulated pair potentials. See the pair_eam command for further details on the setfl format.

- lines 1,2,3 = comments (ignored)
- line 4: \( N_{\text{elements}} \), Element1 Element2 ... ElementN
- line 5: \( N_{\rho}, d_{\rho}, N_{r}, d_{r}, \text{cutoff} \)

Following the 5 header lines are \( N_{\text{elements}} \) sections, one for each element, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function \( F(\rho) \) (\( N_{\rho} \) values)
- density function \( \rho(r) \) (\( N_{r} \) values)

Following the \( N_{\text{elements}} \) sections, \( N_{r} \) values for each pair potential \( \phi(r) \) array are listed for all \( i,j \) element pairs in the same format as other arrays. Since these interactions are symmetric (\( i,j = j,i \)) only \( \phi \) arrays with \( i \geq j \) are listed, in the following order:

\[ i,j = (1,1), (2,1), (2,2), (3,1), (3,2), (3,3), (4,1), \ldots, (N_{\text{elements}}, N_{\text{elements}}). \]
The tabulated values for each $\phi$ function are listed as $r \ast \phi$ (in units of eV-Angstroms), since they are for atom pairs, the same as for other EAM files.

After the $\phi(r)$ arrays, each of the $u(r)$ arrays are listed in the same order with the same assumptions of symmetry. Directly following the $u(r)$, the $w(r)$ arrays are listed. Note that $\phi(r)$ is the only array tabulated with a scaling by $r$.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, no special mixing rules are needed, since the ADP potential files specify alloy interactions explicitly.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.2.4 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package.

18.2.5 Related commands

pair_coeff, pair_eam

Default: none

(Singh) Singh and Warner, Acta Mater, 58, 5797-5805 (2010),
18.3 pair_style agni command

18.4 pair_style agni/omp command

18.4.1 Syntax

```
pair_style agni
```

18.4.2 Examples

```
pair_style agni
pair_coeff * * Al.agni Al
```

18.4.3 Description

Style `agni` style computes the many-body vectorial force components for an atom as

\[
F^u_i = \sum_t N_t \alpha_t \cdot \exp \left[ -\frac{\left( \frac{d^u_{i,t}}{l} \right)^2}{2} \right]
\]

\[
d^u_{i,t} = \| V^u_i(\eta) - V^u_t(\eta) \|
\]

\[
V^u_i(\eta) = \sum_{j \neq i} \frac{r_{ij}}{r_{ij}} \cdot e^{-\left( \frac{2\pi}{
} \right)^2 \cdot f_d(r_{ij})}
\]

\[
f_d(r_{ij}) = \frac{1}{2} \left[ \cos \left( \frac{\pi r_{ij}}{R_c} \right) + 1 \right]
\]

*u* labels the individual components, i.e. *x*, *y* or *z*, and *V* is the corresponding atomic fingerprint. *d* is the Euclidean distance between any two atomic fingerprints. A total of *N_t* reference atomic environments are considered to construct the force field file. *\alpha_t* and *l* are the weight coefficients and length scale parameter of the non-linear regression model.

The method implements the recently proposed machine learning access to atomic forces as discussed extensively in the following publications - *(Botu1)* and *(Botu2)*. The premise of the method is to map the atomic environment numerically into a fingerprint, and use machine learning methods to create a mapping to the vectorial atomic forces.

Only a single pair_coeff command is used with the `agni` style which specifies an AGNI potential file containing the parameters of the force field for the needed elements. These are mapped to LAMMPS atom types by specifying *N* additional arguments after the filename in the pair_coeff command, where *N* is the number of LAMMPS atom types:

- filename
- *N* element names = mapping of AGNI elements to atom types

See the `pair_coeff` doc page for alternate ways to specify the path for the force field file.

An AGNI force field is fully specified by the filename which contains the parameters of the force field, i.e., the reference training environments used to construct the machine learning force field. Example force field and input files are provided in the examples/USER/misc/agni directory.

```

```

Styles with `omp` suffix is functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated style takes the same arguments and should produce the same results, except for round-off and precision issues.
The accelerated style is part of the USER-OMP. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated style explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.4.4 Restrictions

Currently, only elemental systems are implemented. Also, the method only provides access to the forces and not energies or stresses. The lack of potential energy data makes this pair style incompatible with several of the minimizer algorithms like cg or sd. It should work with damped dynamics based minimizers like fire or quickmin. However, one can access the energy via thermodynamic integration of the forces as discussed in (Botu3). This pair style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The AGNI force field files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the AGNI potential with any LAMMPS units, but you would need to create your own AGNI potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

18.13.3 Description

The *airebo* pair style computes the Adaptive Intermolecular Reactive Empirical Bond Order (AIREBO) Potential of *(Stuart)* for a system of carbon and/or hydrogen atoms. Note that this is the initial formulation of AIREBO from 2000, not the later formulation.

The *airebo/morse* pair style computes the AIREBO-M potential, which is equivalent to AIREBO, but replaces the LJ term with a Morse potential. The Morse potentials are parameterized by high-quality quantum chemistry (MP2) calculations and do not diverge as quickly as particle density increases. This allows AIREBO-M to retain accuracy to much higher pressures than AIREBO (up to 40 GPa for Polyethylene). Details for this potential and its parameterization are given in *(O’Conner)*.

The *rebo* pair style computes the Reactive Empirical Bond Order (REBO) Potential of *(Brenner)*. Note that this is the so-called second generation REBO from 2002, not the original REBO from 1990. As discussed below, second generation REBO is closely related to the initial AIREBO; it is just a subset of the potential energy terms with a few slightly different parameters.

The AIREBO potential consists of three terms:

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} \left[ E_{REBO}^{ij} + E_{LJ}^{ij} + \sum_{k \neq i, j} \sum_{l \neq i, j, k} E_{TORSION}^{ijkl} \right]
\]

By default, all three terms are included. For the *airebo* style, if the first two optional flag arguments to the pair_style command are included, the LJ and torsional terms can be turned off. Note that both or neither of the flags must be included. If both of the LJ an torsional terms are turned off, it becomes the second-generation REBO potential, with a small caveat on the spline fitting procedure mentioned below. This can be specified directly as pair_style rebo with no additional arguments.

The detailed formulas for this potential are given in *(Stuart)*; here we provide only a brief description.

The \( E_{REBO} \) term has the same functional form as the hydrocarbon REBO potential developed in *(Brenner)*. The coefficients for \( E_{REBO} \) in AIREBO are essentially the same as Brenner’s potential, but a few fitted spline values are slightly different. For most cases the \( E_{REBO} \) term in AIREBO will produce the same energies, forces and statistical averages as the original REBO potential from which it was derived. The \( E_{REBO} \) term in the AIREBO potential gives the model its reactive capabilities and only describes short-ranged C-C, C-H and H-H interactions (\( r < 2 \) Angstroms). These interactions have strong coordination-dependence through a bond order parameter, which adjusts the attraction between the I,J atoms based on the position of other nearby atoms and thus has 3- and 4-body dependence.

The \( E_{LJ} \) term adds longer-ranged interactions (\( 2 < r < \text{cutoff} \)) using a form similar to the standard Lennard Jones potential. The \( E_{LJ} \) term in AIREBO contains a series of switching functions so that the short-ranged LJ repulsion (\( 1/r^{12} \)) does not interfere with the energetics captured by the \( E_{REBO} \) term. The extent of the \( E_{LJ} \) interactions is determined by the \textsc{cutoff} argument to the pair_style command which is a scale factor. For each type pair (C-C, C-H, H-H) the cutoff is obtained by multiplying the scale factor by the sigma value defined in the potential file for that type pair. In the standard AIREBO potential, \( \sigma_{CC} = 3.4 \) Angstroms, so with a scale factor of 3.0 (the argument in \textsc{cutoff}), the resulting \( E_{LJ} \) cutoff would be 10.2 Angstroms.

By default, the longer-ranged interaction is smoothly switched off between 2.16 and 3.0 \( \sigma \). By specifying \textsc{cutoff_min} in addition to \textsc{cutoff}, the switching can be configured to take place between \textsc{cutoff_min} and \textsc{cutoff}. \textsc{cutoff_min} can only be specified if all optional arguments are given.

The \( E_{TORSION} \) term is an explicit 4-body potential that describes various dihedral angle preferences in hydrocarbon configurations.

Only a single pair_coeff command is used with the *airebo*, *airebo* or *rebo* style which specifies an AIREBO, REBO, or AIREBO-M potential file with parameters for C and H. Note that as of LAMMPS version 15 May 2019 the *rebo* style in LAMMPS uses its own potential file (CH.rebo). These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:
filename

N element names = mapping of AIREBO elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, if your LAMMPS simulation has 4 atom types and you want the first 3 to be C, and the fourth to be H, you would use the following pair_coeff command:

```
pair_coeff * * CH.airebo C C C H
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three C arguments map LAMMPS atom types 1,2,3 to the C element in the AIREBO file. The final H argument maps LAMMPS atom type 4 to the H element in the SW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a airebo potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The parameters/coefficients for the AIREBO potentials are listed in the CH.airebo file to agree with the original (Stuart) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done cautiously.

Similarly the parameters/coefficients for the AIREBO-M potentials are listed in the CH.airebo-m file to agree with the (O’Connor) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done cautiously. The AIREBO-M Morse potentials were parameterized using a cutoff of 3.0 (σ). Modifying this cutoff may impact simulation accuracy.

This pair style tallies a breakdown of the total AIREBO potential energy into sub-categories, which can be accessed via the compute pair command as a vector of values of length 3. The 3 values correspond to the following sub-categories:

1. $E_{REBO} = REBO$ energy
2. $E_{LJ} = Lennard-Jones$ energy
3. $E_{TORSION} = Torsion$ energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```
compute 0 all pair airebo
variable REBO equal c_0[1]
variable LJ equal c_0[2]
variable TORSION equal c_0[3]
thermo_style custom step temp epair v_REBO v_LJ v_TORSION
```

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:
These pair styles do not support the `pair_modify mix, shift, table, and tail` options.

These pair styles do not write their information to `binary restart files`, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

These pair styles can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.

### 18.13.4 Restrictions

These pair styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

These pair potentials require the `newton` setting to be “on” for pair interactions.

The CH.airebo and CH.airebo-m potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the AIREBO, AIREBO-M or REBO potential with any LAMMPS units, but you would need to create your own AIREBO or AIREBO-M potential file with coefficients listed in the appropriate units, if your simulation does not use “metal” units.

pair_coeff 1 2 atm 2 0.100
pair_coeff 2 2 atm 2 0.125
```
18.14.3 Description

The *atm* style computes a 3-body *Axilrod-Teller-Muto* potential for the energy $E$ of a system of atoms as

$$
E = \nu \frac{1 + 3 \cos \gamma_1 \cos \gamma_2 \cos \gamma_3}{r_{12}^{3/2} r_{23}^{3/2} r_{31}^{3/2}}
$$

where $\nu$ is the three-body interaction strength. The distances between pairs of atoms $r_{12}$, $r_{23}$, $r_{31}$ and the angles $\gamma_1$, $\gamma_2$, $\gamma_3$ are as shown in this diagram:

![Diagram showing distances and angles for the atm potential](image)

Note that for the interaction between a triplet of atoms $I$, $J$, $K$, there is no “central” atom. The interaction is symmetric with respect to permutation of the three atoms. Thus the $\nu$ value is the same for all those permutations of the atom types of $I$, $J$, $K$ and needs to be specified only once, as discussed below.

The *atm* potential is typically used in combination with a two-body potential using the *pair_style hybrid/overlay* command as in the example above.

The potential for a triplet of atom is calculated only if all 3 distances $r_{12}$, $r_{23}$, $r_{31}$ between the 3 atoms satisfy $r_{12} < \text{cutoff}$. In addition, the product of the 3 distances $r_{12} r_{23} r_{31} < \text{cutoff triple}^3$ is required, which excludes from calculation the triplets with small contribution to the interaction.

The following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the restart files read by the *read_restart* commands:

- $K =$ atom type of the third atom (1 to $N_{\text{types}}$)
- $\nu =$ prefactor (energy/distance$^9$ units)

$K$ can be specified in one of two ways. An explicit numeric value can be used, as in the second example above. $J \leq K$ is required. LAMMPS sets the coefficients for the other 5 symmetric interactions to the same values. E.g. if $I = 1$, $J = 2$, $K = 3$, then these 6 values are set to the specified $\nu$: $\nu_{123}$, $\nu_{132}$, $\nu_{213}$, $\nu_{231}$, $\nu_{312}$, $\nu_{321}$. This enforces the symmetry discussed above.

A wildcard asterisk can be used for $K$ to set the coefficients for multiple triplets of atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If $N$ equals the number of atom types, then an asterisk with no numeric values means all types from 1 to $N$. A leading asterisk means all types from 1 to $n$ (inclusive). A trailing asterisk means all types from $n$ to $N$ (inclusive). A middle asterisk means all types from $m$ to $n$ (inclusive). Note that only type triplets with $J \leq K$ are considered; if asterisks imply type triplets where $K < J$, they are ignored.

Note that a *pair_coeff* command can override a previous setting for the same $I$, $J$, $K$ triplet. For example, these commands set $\nu$ for all $I$, $J$, $K$ triplets, then overwrite nu for just the $I$, $J$, $K = 2$, 3, 4 triplet:

```
pair_coeff * * * 0.25
pair_coeff 2 3 4 0.1
```

Note that for a simulation with a single atom type, only a single entry is required, e.g.

```
pair_coeff 1 1 1 0.25
```

For a simulation with two atom types, four *pair_coeff* commands will specify all possible nu values:
For a simulation with three atom types, ten pair_coeffs will specify all possible \( \nu \) values:

\[
\begin{align*}
\text{pair\_coeff} &\quad 1 \quad 1 \quad \nu_1 \\
\text{pair\_coeff} &\quad 1 \quad 1 \quad \nu_2 \\
\text{pair\_coeff} &\quad 1 \quad 2 \quad \nu_3 \\
\text{pair\_coeff} &\quad 2 \quad 2 \quad \nu_4 \\
\text{pair\_coeff} &\quad 1 \quad 3 \quad \nu_5 \\
\text{pair\_coeff} &\quad 2 \quad 3 \quad \nu_6 \\
\text{pair\_coeff} &\quad 2 \quad 2 \quad \nu_7 \\
\text{pair\_coeff} &\quad 3 \quad 3 \quad \nu_8 \\
\text{pair\_coeff} &\quad 2 \quad 3 \quad \nu_9 \\
\text{pair\_coeff} &\quad 3 \quad 3 \quad \nu_{10}
\end{align*}
\]

By default the \( \nu \) value for all triplets is set to 0.0. Thus it is not required to provide pair_coeffs that enumerate triplet interactions for all \( K \) types. If some \( I, J, K \) combination is not specified, then there will be no 3-body ATM interactions for that combination and all its permutations. However, as with all pair styles, it is required to specify a pair_coeff command for all \( I, J \) combinations, else an error will result.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair styles do not support the pair_modify mix, shift, table, and tail options.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. However, if the atm potential is used in combination with other potentials using the pair_style hybrid/overlay command then pair_coeff commands need to be re-specified in the restart input script.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

**18.14.4 Restrictions**

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

**18.14.5 Related commands**

pair_coeff

**Default:** none

18.15 pair_style awpmd/cut command

18.15.1 Syntax

`pair_style awpmd/cut Rc keyword value ...`

- \( Rc \) = global cutoff, -1 means cutoff of half the shortest box length
- zero or more keyword/value pairs may be appended
- keyword = `hartree` or `dproduct` or `uhf` or `free` or `pbc` or `fix` or `harm` or `ermscale` or `flex_press`

  - `hartree` value = none
  - `dproduct` value = none
  - `uhf` value = none

  - `pbc` value = `Plen`
    - `Plen` = periodic width of electron = -1 or positive value (distance units)
  - `fix` value = `Flen`
    - `Flen` = fixed width of electron = -1 or positive value (distance units)
  - `harm` value = `width`
    - `width` = harmonic width constraint
  - `ermscale` value = `factor`
    - `factor` = scaling between electron mass and width variable mass
  - `flex_press` value = none

18.15.2 Examples

```plaintext
pair_style awpmd/cut -1
pair_style awpmd/cut 40.0 uhf free
pair_coeff * *
pair_coeff 2 2 20.0
```

18.15.3 Description

This pair style contains an implementation of the Antisymmetrized Wave Packet Molecular Dynamics (AWPMD) method. Need citation here. Need basic formulas here. Could be links to other documents.

\( Rc \) is the cutoff.

The `pair_style` command allows for several optional keywords to be specified.

The `hartree`, `dproduct`, and `uhf` keywords specify the form of the initial trial wave function for the system. If the `hartree` keyword is used, then a Hartree multielectron trial wave function is used. If the `dproduct` keyword is used, then a trial function which is a product of two determinants for each spin type is used. If the `uhf` keyword is used, then an unrestricted Hartree-Fock trial wave function is used.

The `free`, `pbc`, and `fix` keywords specify a width constraint on the electron wave packets. If the `free` keyword is specified, then there is no constraint. If the `pbc` keyword is used and `Plen` is specified as -1, then the maximum width is half the shortest box length. If \( Plen \) is a positive value, then the value is the maximum width. If the `fix` keyword is used and `Flen` is specified as -1, then electrons have a constant width that is read from the data file. If `Flen` is a positive value, then the constant width for all electrons is set to `Flen`.

The `harm` keyword allow oscillations in the width of the electron wave packets. More details are needed.
The `ermscale` keyword specifies a unitless scaling factor between the electron masses and the width variable mass. More details needed.

If the `flex_press` keyword is used, then a contribution from the electrons is added to the total virial and pressure of the system.

This potential is designed to be used with `atom_style wavepacket` definitions, in order to handle the description of systems with interacting nuclei and explicit electrons.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- `cutoff` (distance units)

For `awpmd/cut`, the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the `pair_style` command is used.

### Mixing, shift, table, tail correction, restart, rRESPA info:

The `pair_modify` mix, shift, table, and tail options are not relevant for this pair style.

This pair style writes its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 18.16 `pair_style beck` command

### 18.17 `pair_style beck/gpu` command

### 18.18 `pair_style beck/omp` command

### 18.18.1 Syntax
pair_style beck Rc

• Rc = cutoff for interactions (distance units)

18.18.2 Examples

pair_style beck 8.0
pair_coeff * * 399.671876712 0.0000867636112694 0.675 4.390 0.0003746
pair_coeff 1 1 399.671876712 0.0000867636112694 0.675 4.390 0.0003746 6.0

18.18.3 Description

Style beck computes interactions based on the potential by (Beck), originally designed for simulation of Helium. It includes truncation at a cutoff distance Rc.

\[
E(r) = A \exp \left[ -\alpha r - \beta r^6 \right] - \frac{B}{(r^2 + a^2)^3} \left( 1 + \frac{2.709 + 3a^2}{r^2 + a^2} \right) \quad r < R_c
\]

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands.

• A (energy units)
• B (energy-distance^6 units)
• a (distance units)
• \(\alpha\) (1/distance units)
• \(\beta\) (1/distance^6 units)
• cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff \(R_c\) is used.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, coefficients must be specified. No default mixing rules are used.

This pair style does not support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.
This pair style does not support the pair_modify tail option for adding long-range tail corrections.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.19 pair_style body/nparticle command

18.19.1 Syntax

```
pair_style body/nparticle cutoff
cutoff = global cutoff for interactions (distance units)
```

18.19.2 Examples

```
pair_style body/nparticle 3.0
pair_coeff * * 1.0 1.0
pair_coeff 1 1 1.0 1.5 2.5
```

18.19.3 Description

Style body/nparticle is for use with body particles and calculates pairwise body/body interactions as well as interactions between body and point-particles. See the Howto body doc page for more details on using body particles.

This pair style is designed for use with the “nparticle” body style, which is specified as an argument to the “atom-style body” command. See the Howto body doc page for more details about the body styles LAMMPS supports. The “nparticle” style treats a body particle as a rigid body composed of N sub-particles.

The coordinates of a body particle are its center-of-mass (COM). If the COMs of a pair of body particles are within the cutoff (global or type-specific, as specified above), then all interactions between pairs of sub-particles in the two body particles are computed. E.g. if the first body particle has 3 sub-particles, and the second has 10, then 30 interactions are computed and summed to yield the total force and torque on each body particle.
Note: In the example just described, all 30 interactions are computed even if the distance between a particular pair of sub-particles is greater than the cutoff. Likewise, no interaction between two body particles is computed if the two COMs are further apart than the cutoff, even if the distance between some pairs of their sub-particles is within the cutoff. Thus care should be used in defining the cutoff distances for body particles, depending on their shape and size.

Similar rules apply for a body particle interacting with a point particle. The distance between the two particles is calculated using the COM of the body particle and the position of the point particle. If the distance is within the cutoff and the body particle has N sub-particles, then N interactions with the point particle are computed and summed. If the distance is not within the cutoff, no interactions between the body and point particle are computed.

The interaction between two sub-particles, or a sub-particle and point particle, or between two point particles is computed as a Lennard-Jones interaction, using the standard formula

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < R_c \]

where \( R_c \) is the cutoff. As explained above, an interaction involving one or two body sub-particles may be computed even for \( r > R_c \).

For style \textit{body}, the following coefficients must be defined for each pair of atoms types via the \texttt{pair_coeff} command as in the examples above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I \neq J, the epsilon and sigma coefficients and cutoff distance for all of this pair style can be mixed. The default mix value is \textit{geometric}. See the \texttt{pair_modify} command for details.

This pair style does not support the \texttt{pair_modify} shift, table, and tail options.

This pair style does not write its information to binary restart files.

This pair style can only be used via the \texttt{pair} keyword of the \texttt{run_style respa} command. It does not support the \texttt{inner}, \texttt{middle}, \texttt{outer} keywords.

18.19.4 Restrictions

This style is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the \texttt{Build package} doc page for more info.

Defining particles to be bodies so they participate in body/body or body/particle interactions requires the use of the \texttt{atom_style body} command.

18.20 pair_style body/rounded/polygon command

18.20.1 Syntax

```plaintext
pair_style body/rounded/polygon c_n c_t mu delta_ua cutoff
```

- `c_n` = normal damping coefficient
- `c_t` = tangential damping coefficient
- `mu` = normal friction coefficient during gross sliding
- `delta_ua` = multiple contact scaling factor
- `cutoff` = global separation cutoff for interactions (distance units), see below for definition

18.20.2 Examples

```plaintext
pair_style body/rounded/polygon 20.0 5.0 0.0 1.0 0.5
pair_coeff * * 100.0 1.0
pair_coeff 1 1 100.0 1.0
```

18.20.3 Description

Style `body/rounded/polygon` is for use with 2d models of body particles of style `rounded/polygon`. It calculates pairwise body/body interactions which can include body particles modeled as 1-vertex circular disks with a specified diameter. See the Howto body doc page for more details on using body rounded/polygon particles.

This pairwise interaction between rounded polygons is described in Fraige, where a polygon does not have sharp corners, but is rounded at its vertices by circles centered on each vertex with a specified diameter. The edges of the polygon are defined between pairs of adjacent vertices. The circle diameter for each polygon is specified in the data file read by the read data command. This is a 2d discrete element model (DEM) which allows for multiple contact points.

Note that when two particles interact, the effective surface of each polygon particle is displaced outward from each of its vertices and edges by half its circle diameter (as in the diagram below of a gray and yellow square particle). The interaction forces and energies between two particles are defined with respect to the separation of their respective rounded surfaces, not by the separation of the vertices and edges themselves.

This means that the specified cutoff in the pair_style command is the cutoff distance, \( r_c \), for the surface separation, \( \delta_n \) (see figure below). This is the distance at which two particles no longer interact. If \( r_c \) is specified as 0.0, then it is a contact-only interaction. I.e. the two particles must overlap in order to exert a repulsive force on each other. If \( r_c > 0.0 \), then the force between two particles will be attractive for surface separations from 0 to \( r_c \), and repulsive once the particles overlap.

Note that unlike for other pair styles, the specified cutoff is not the distance between the centers of two particles at which they stop interacting. This center-to-center distance depends on the shape and size of the two particles and their relative orientation. LAMMPS takes that into account when computing the surface separation distance and applying the \( r_c \) cutoff.
The forces between vertex-vertex, vertex-edge, and edge-edge overlaps are given by:

\[ F_n = \begin{cases} 
  k_n \delta_n - c_n v_n & \delta_n \leq 0 \\
  -k_n a \delta_n - c_n v_n & 0 < \delta_n \leq r_c \\
  0 & \delta_n > r_c 
\end{cases} \]

\[ F_t = \begin{cases} 
  \mu k_n \delta_n - c_t v_t & \delta_n \leq 0 \\
  0 & \delta_n > 0 
\end{cases} \]

Note that \( F_n \) and \( F_t \) are functions of the surface separation \( \delta_n = d - (R_i + R_j) \). In this model, when \((R_i + R_j) < d < (R_i + R_j) + r_c\), that is, \(0 < \delta_n < r_c\), the cohesive region of the two surfaces overlap and the two surfaces are attractive to each other.

In Fraige, the tangential friction force between two particles that are in contact is modeled differently prior to gross sliding (i.e. static friction) and during gross-sliding (kinetic friction). The latter takes place when the tangential
deformation exceeds the Coulomb frictional limit. In the current implementation, however, we do not take into account frictional history, i.e. we do not keep track of how many time steps the two particles have been in contact nor calculate the tangential deformation. Instead, we assume that gross sliding takes place as soon as two particles are in contact.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file read by the `read_data` command:

- \( k_n \) (energy/distance\(^2\) units)
- \( k_{na} \) (energy/distance\(^2\) units)

Effectively, \( k_n \) and \( k_{na} \) are the slopes of the red lines in the plot above for force versus surface separation, for \( \delta_n < 0 \) and \( 0 < \delta_n < r_c \) respectively.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to `binary restart files`. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 18.20.4 Restrictions

These pair styles are part of the BODY package. They are only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

### 18.20.5 Related commands

### 18.21 pair_style body/rounded/polyhedron command

#### 18.21.1 Syntax

```
pair_style body/rounded/polyhedron c_n c_t mu delta_ua cutoff
```

- \( c_n \) = normal damping coefficient
- \( c_t \) = tangential damping coefficient
- \( mu \) = normal friction coefficient during gross sliding
- \( delta_ua \) = multiple contact scaling factor
- \( cutoff \) = global separation cutoff for interactions (distance units), see below for definition
18.21.2 Examples

```
pair_style body/rounded/polyhedron 20.0 5.0 0.0 1.0 0.5
pair_coeff * * 100.0 1.0
pair_coeff 1 1 100.0 1.0
```

18.21.3 Description

Style `body/rounded/polyhedron` is for use with 3d models of body particles of style `rounded/polyhedron`. It calculates pairwise body/body interactions which can include body particles modeled as 1-vertex spheres with a specified diameter. See the `Howto body` doc page for more details on using body rounded/polyhedron particles.

This pairwise interaction between the rounded polyhedra is described in Wang, where a polyhedron does not have sharp corners and edges, but is rounded at its vertices and edges by spheres centered on each vertex with a specified diameter. The edges if the polyhedron are defined between pairs of adjacent vertices. Its faces are defined by a loop of edges. The sphere diameter for each polygon is specified in the data file read by the `read data` command. This is a discrete element model (DEM) which allows for multiple contact points.

Note that when two particles interact, the effective surface of each polyhedron particle is displaced outward from each of its vertices, edges, and faces by half its sphere diameter. The interaction forces and energies between two particles are defined with respect to the separation of their respective rounded surfaces, not by the separation of the vertices, edges, and faces themselves.

This means that the specified cutoff in the `pair_style` command is the cutoff distance, $r_c$, for the surface separation, $\delta_n$ (see figure below). This is the distance at which two particles no longer interact. If $r_c$ is specified as 0.0, then it is a contact-only interaction. I.e. the two particles must overlap in order to exert a repulsive force on each other. If $r_c > 0.0$, then the force between two particles will be attractive for surface separations from 0 to $r_c$, and repulsive once the particles overlap.

Note that unlike for other pair styles, the specified cutoff is not the distance between the centers of two particles at which they stop interacting. This center-to-center distance depends on the shape and size of the two particles and their relative orientation. LAMMPS takes that into account when computing the surface separation distance and applying the $r_c$ cutoff.

The forces between vertex-vertex, vertex-edge, vertex-face, edge-edge, and edge-face overlaps are given by:

$$F_n = \begin{cases} k_n \delta_n - c_n v_n, & \delta_n \leq 0 \\ -k_n a \delta_n - c_n v_n, & 0 < \delta_n \leq r_c \\ 0, & \delta_n > r_c \end{cases}$$

$$F_t = \begin{cases} \mu k_n \delta_n - c_t v_t, & \delta_n \leq 0 \\ 0, & \delta_n > 0 \end{cases}$$
In *Wang*, the tangential friction force between two particles that are in contact is modeled differently prior to gross sliding (i.e. static friction) and during gross-sliding (kinetic friction). The latter takes place when the tangential deformation exceeds the Coulomb frictional limit. In the current implementation, however, we do not take into account frictional history, i.e. we do not keep track of how many time steps the two particles have been in contact nor calculate the tangential deformation. Instead, we assume that gross sliding takes place as soon as two particles are in contact.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file read by the `read_data` command:

- $k_n$ (energy/distance^2 units)
- $k_{na}$ (energy/distance^2 units)

Effectively, $k_n$ and $k_{na}$ are the slopes of the red lines in the plot above for force versus surface separation, for $\delta_n < 0$ and $0 < \delta_n < r_c$ respectively.
Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to binary restart files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 18.21.4 Restrictions

These pair styles are part of the BODY package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

### 18.22 pair_style bop command

#### 18.22.1 Syntax

```
pair_style bop keyword ...
```

- zero or more keywords may be appended
- keyword = save

```
save = pre-compute and save some values
```

#### 18.22.2 Examples

```
pair_style bop
pair_coeff * * ../potentials/CdTe_bop Cd Te
pair_style bop save
pair_coeff * * ../potentials/CdTe.bop.table Cd Te Te
comm_modify cutoff 14.70
```
18.22.3 Description

The \textit{bop} pair style computes Bond-Order Potentials (BOP) based on quantum mechanical theory incorporating both $\sigma$ and $\pi$ bonding. By analytically deriving the BOP from quantum mechanical theory its transferability to different phases can approach that of quantum mechanical methods. This potential is similar to the original BOP developed by Pettifor \cite{Pettifor_1,Pettifor_2,Pettifor_3} and later updated by Murdick, Zhou, and Ward \cite{Murdick,Ward}. Currently, BOP potential files for these systems are provided with LAMMPS: AlCu, CCu, CdTe, CdTeSe, CdZnTe, CuH, GaAs. A system with only a subset of these elements, including a single element (e.g. C or Cu or Al or Ga or Zn or CdZn), can also be modeled by using the appropriate alloy file and assigning all atom types to the single element or subset of elements via the \textit{pair_coeff} command, as discussed below.

The BOP potential consists of three terms:

$$ E = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{i} \phi_{ij}(r_{ij}) - \sum_{i=1}^{N} \sum_{j=1}^{i} \beta_{\sigma,ij}(r_{ij}) \cdot \Theta_{\sigma,ij} - \sum_{i=1}^{N} \sum_{j=1}^{i} \beta_{\pi,ij}(r_{ij}) \cdot \Theta_{\pi,ij} + U_{\text{prom}} $$

where $\phi_{ij}(r_{ij})$ is a short-range two-body function representing the repulsion between a pair of ion cores, $\beta_{\sigma,ij}(r_{ij})$ and $\beta_{\pi,ij}(r_{ij})$ are respectively sigma and $\pi$ bond integrals, $\Theta_{\sigma,ij}$ and $\Theta_{\pi,ij}$ are $\sigma$ and $\pi$ bond-orders, and $U_{\text{prom}}$ is the promotion energy for sp-valent systems.

The detailed formulas for this potential are given in Ward \cite{Ward}; here we provide only a brief description.

The repulsive energy $\phi_{ij}(r_{ij})$ and the bond integrals $\beta_{\sigma,ij}(r_{ij})$ and $\beta_{\pi,ij}(r_{ij})$ are functions of the interatomic distance $r_{ij}$ between atom $i$ and $j$. Each of these potentials has a smooth cutoff at a radius of $r_{\text{cut},ij}$. These smooth cutoffs ensure stable behavior at situations with high sampling near the cutoff such as melts and surfaces.

The bond-orders can be viewed as environment-dependent local variables that are $ij$ bond specific. The maximum value of the $\sigma$ bond-order ($\Theta_{\sigma}$) is 1, while that of the $\pi$ bond-order ($\Theta_{\pi}$) is 2, attributing to a maximum value of the total bond-order ($\Theta_{\sigma} + \Theta_{\pi}$) of 3. The $\sigma$ and $\pi$ bond-orders reflect the ubiquitous single-, double-, and triple- bond behavior of chemistry. Their analytical expressions can be derived from tight-binding theory by recursively expanding an inter-site Green’s function as a continued fraction. To accurately represent the bonding with a computationally efficient potential formulation suitable for MD simulations, the derived BOP only takes (and retains) the first two levels of the recursive representations for both the $\sigma$ and $\pi$ bond-orders. Bond-order terms can be understood in terms of molecular orbital hopping paths based upon the Cyrot-Lackmann theorem \cite{Pettifor_1}. The $\pi$ bond-order with a half-full valence shell is used to interpolate the bond-order expression that incorporated explicit valance band filling. This $\pi$ bond-order expression also contains also contains a three-member ring term that allows implementation of an asymmetric density of states, which helps to either stabilize or destabilize close-packed structures. The $\pi$ bond-order includes hopping paths of length 4. This enables the incorporation of dihedral angles effects.

Note: Note that unlike for other potentials, cutoffs for BOP potentials are not set in the \textit{pair_style} or \textit{pair_coeff} command; they are specified in the BOP potential files themselves. Likewise, the BOP potential files list atomic masses; thus you do not need to use the \textit{mass} command to specify them. Note that for BOP potentials with hydrogen, you will likely want to set the mass of H atoms to be 10x or 20x larger to avoid having to use a tiny timestep. You can do this by using the \textit{mass} command after using the \textit{pair_coeff} command to read the BOP potential file.

One option can be specified as a keyword with the \textit{pair_style} command.

The \textit{save} keyword gives you the option to calculate in advance and store a set of distances, angles, and derivatives of angles. The default is to not do this, but to calculate them on-the-fly each time they are needed. The former may be faster, but takes more memory. The latter requires less memory, but may be slower. It is best to test this option to optimize the speed of BOP for your particular system configuration.

Only a single \textit{pair_coeff} command is used with the \textit{bop} style which specifies a BOP potential file, with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the \textit{pair_coeff} command, where N is the number of LAMMPS atom types:
• filename
• N element names = mapping of BOP elements to atom types

As an example, imagine the CdTe.bop file has BOP values for Cd and Te. If your LAMMPS simulation has 4 atoms

types and you want the first 3 to be Cd, and the fourth to be Te, you would use the following pair_coeff command:

```
pair_coeff * * CdTe Cd Cd Cd Te
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Cd arguments map LAMMPS
atom types 1,2,3 to the Cd element in the BOP file. The final Te argument maps LAMMPS atom type 4 to the Te

element in the BOP file.

BOP files in the potentials directory of the LAMMPS distribution have a “.bop” suffix. The potentials are in tabulated

form containing pre-tabulated pair functions for \( \phi_{ij}(r_{ij}) \), \( \beta_{\sigma,ij}(r_{ij}) \), and \( \beta_{\pi,ij}(r_{ij}) \).

The parameters/coefficients format for the different kinds of BOP files are given below with variables matching the

formulation of Ward (Ward) and Zhou (Zhou). Each header line containing a “:” is preceded by a blank line.

**No angular table file format:**

The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of \( g \) is given

below with variables matching the formulation of Ward (Ward). This format also assumes the angular functions have

the formulation of (Ward).

- Line 1: # elements N

The first line is followed by N lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1: nr, nBOt (nr is the number of divisions the radius is broken into for function tables and MUST be a

  factor of 5; nBOt is the number of divisions for the tabulated values of \( \Theta_{S,ij} \))
- Line 2: delta_1-delta_7 (if all are not used in the particular

  formulation, set unused values to 0.0)

Following this N lines for e_1-e_N containing p_pi.

- Line 3: p_pi (for e_1)
- Line 4: p_pi (for e_2 and continues to e_N)

The next section contains several pair constants for the number of interaction types e_i-e_j, with i=1->N, j=i->N

- Line 1: r_cut (for e_1-e_1 interactions)
- Line 2: c_sigma, a_sigma, c_pi, a_pi
- Line 3: delta_sigma, delta_pi
- Line 4: f_sigma, k_sigma, delta_3 (This delta_3 is similar to that of the previous section but is interaction type

  dependent)

The next section contains a line for each three body interaction type e_j-e_i-e_k with i=0->N, j=0->N, k=j->N

- Line 1: g_(sigma0), g_(sigma1), g_(sigma2) (These are coefficients for \( g_{(sigma,jik)}(\Theta_{ijk}) \) for e_1-e_1-

  e_1 interaction. Ward contains the full expressions for the constants as functions of \( b_{(sigma,jik)}, p_{(sigma,jik)},

  u_{(sigma,jik)} \))
- Line 2: g_(sigma0), g_(sigma1), g_(sigma2) (for e_1-e_1-e_2)

The next section contains a block for each interaction type for the \( \phi_{ij}(r_{ij}) \). Each block has nr entries with 5 entries

per line.
The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of $g$ is given below with variables matching the formulation of Ward (Ward). This format also assumes the angular functions have the formulation of (Zhou).

- Line 1: # elements N
The first line is followed by N lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1: nr, ntheta, nBOt (nr is the number of divisions the radius is broken into for function tables and MUST be a factor of 5; ntheta is the power of the power of the spline used to fit the angular function; nBOt is the number of divisions for the tabulated values of THETA_(S,ij)
- Line 2: delta_1-delta_7 (if all are not used in the particular formulation, set unused values to 0.0)

Following this N lines for e_1-e_N containing p_pi.

- Line 3: p_pi (for e_1)
- Line 4: p_pi (for e_2 and continues to e_N)

The next section contains several pair constants for the number of interaction types e_i-e_j, with i=1->N, j=i->N

- Line 1: r_cut (for e_1-e_1 interactions)
- Line 2: c_sigma, a_sigma, c_pi, a_pi
- Line 3: delta_sigma, delta_pi
- Line 4: f_sigma, k_sigma, delta_3 (This delta_3 is similar to that of the previous section but is interaction type dependent)

The next section contains a line for each three body interaction type e_j-e_i-e_k with i=0->N, j=0->N, k=j->N

- Line 1: g0, g1, g2… (These are coefficients for the angular spline of the g_(sigma,jik)(THETA_ijk) for e_1-e_1-e_1 interaction. The function can contain up to 10 term thus 10 constants. The first line can contain up to five constants. If the spline has more than five terms the second line will contain the remaining constants. The following lines will then contain the constants for the remaining g0, g1, g2… (for e_1-e_1-e_2) and the other three body interactions

The rest of the table has the same structure as the previous section (see above).

Angular no-spline table file format:

The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of g is given below with variables matching the formulation of Ward (Ward). This format also assumes the angular functions have the formulation of (Zhou).

- Line 1: # elements N

The first two lines are followed by N lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1: nr, ntheta, nBOt (nr is the number of divisions the radius is broken into for function tables and MUST be a factor of 5; ntheta is the number of divisions for the tabulated values of the g angular function; nBOt is the number of divisions for the tabulated values of THETA_(S,ij)
- Line 2: delta_1-delta_7 (if all are not used in the particular formulation, set unused values to 0.0)

Following this N lines for e_1-e_N containing p_pi.

- Line 3: p_pi (for e_1)
- Line 4: p_pi (for e_2 and continues to e_N)

The next section contains several pair constants for the number of interaction types e_i-e_j, with i=1->N, j=i->N
• Line 1: \texttt{r\_cut} (for e\_1-e\_1 interactions)
• Line 2: \texttt{c\_sigma}, \texttt{a\_sigma}, \texttt{c\_pi}, \texttt{a\_pi}
• Line 3: \texttt{delta\_sigma}, \texttt{delta\_pi}
• Line 4: \texttt{f\_sigma}, \texttt{k\_sigma}, \texttt{delta\_3} (This \texttt{delta\_3} is similar to that of the previous section but is interaction type dependent)

The next section contains a line for each three body interaction type e\_j-e\_i-e\_k with i=0->N, j=0->N, k=j->N
• Line 1: \texttt{g(theta1)}, \texttt{g(theta2)}, \texttt{g(theta3)}, \texttt{g(theta4)}, \texttt{g(theta5)} (for the e\_1-e\_1-e\_1 interaction type)
• Line 2: \texttt{g(theta6)}, \texttt{g(theta7)}, \texttt{g(theta8)}, \texttt{g(theta9)}, \texttt{g(theta10)} (this continues until \texttt{ntheta})
• ... 
• Line \texttt{ntheta/5+1}: \texttt{g(theta1)}, \texttt{g(theta2)}, \texttt{g(theta3)}, \texttt{g(theta4)}, \texttt{g(theta5)}, (for the e\_1-e\_1-e\_2 interaction type)

The rest of the table has the same structure as the previous section (see above).

\textbf{Mixing, shift, table tail correction, restart:}

This pair style does not support the \texttt{pair\_modify} mix, shift, table, and tail options.

This pair style does not write its information to \texttt{binary restart files}, since it is stored in potential files. Thus, you need to re-specify the \texttt{pair\_style} and \texttt{pair\_coeff} commands in an input script that reads a restart file.

This pair style can only be used via the \texttt{pair} keyword of the \texttt{run\_style respa} command. It does not support the \texttt{inner}, \texttt{middle}, \texttt{outer} keywords.

\section{18.22.4 Restrictions}

These pair styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the \texttt{Build package} doc page for more info.

These pair potentials require the \texttt{newton} setting to be “on” for pair interactions.

The CdTe.bop and GaAs.bop potential files provided with LAMMPS (see the potentials directory) are parameterized for metal \texttt{units}. You can use the BOP potential with any LAMMPS units, but you would need to create your own BOP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

18.34.3 Description

The born style computes the Born-Mayer-Huggins or Tosi/Fumi potential described in [Fumi and Tosi], given by

\[ E = A \exp \left( \frac{\sigma - r}{\rho} \right) - \frac{C}{r^6} + \frac{D}{r^8} \quad r < r_c \]

where \( \sigma \) is an interaction-dependent length parameter, \( \rho \) is an ionic-pair dependent length parameter, and \( r_c \) is the cutoff.

The styles with coul/long or coul/msm add a Coulombic term as described for the lj/cut pair styles. An additional damping factor is applied to the Coulombic term so it can be used in conjunction with the kspace_style command and its ewald or pppm of msm option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.
If one cutoff is specified for the *born/coul/long* and *born/coul/msm* style, it is used for both the A,C,D and Coulombic terms. If two cutoffs are specified, the first is used as the cutoff for the A,C,D terms, and the second is the cutoff for the Coulombic term.

The *born/coul/wolf* style adds a Coulombic term as described for the Wolf potential in the *coul/wolf* pair style.

The *born/coul/dsf* style computes the Coulomb contribution with the damped shifted force model as in the *coul/dsf* style.

Note that these potentials are related to the *Buckingham potential*.

The following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands, or by mixing as described below:

- A (energy units)
- \( \rho \) (distance units)
- \( \sigma \) (distance units)
- C (energy units * distance units^6)
- D (energy units * distance units^8)
- cutoff (distance units)

The second coefficient, rho, must be greater than zero. The last coefficient is optional. If not specified, the global A,C,D cutoff specified in the pair_style command is used.

For *born/coul/long*, *born/coul/wolf* and *born/coul/dsf* no Coulombic cutoff can be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* command-line switch when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These styles support the *pair_modify* shift option for the energy of the exp(), 1/r^6, and 1/r^8 portion of the pair interaction.

The *born/coul/long* pair style supports the *pair_modify* table option to tabulate the short-range portion of the long-range Coulombic interaction.

These styles support the *pair_modify* tail option for adding long-range tail corrections to energy and pressure.

These styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.
These styles can only be used via the *pair* keyword of the *run_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

### 18.34.4 Restrictions

The *born/coul/long* style is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

### 18.34.5 Related commands

### 18.36 pair_style brownian/omp command

### 18.37 pair_style brownian/poly command

### 18.38 pair_style brownian/poly/omp command

#### 18.38.1 Syntax

```
pair_style style mu flaglog flagfld cutinner cutoff t_target seed flagHI flagVF
```

- **style** = *brownian* or *brownian/poly*
- **mu** = dynamic viscosity (dynamic viscosity units)
- **flaglog** = 0/1 log terms in the lubrication approximation on/off
- **flagfld** = 0/1 to include/exclude Fast Lubrication Dynamics effects
- **cutinner** = inner cutoff distance (distance units)
- **cutoff** = outer cutoff for interactions (distance units)
- **t_target** = target temp of the system (temperature units)
- **seed** = seed for the random number generator (positive integer)
- **flagHI** (optional) = 0/1 to include/exclude 1/r hydrodynamic interactions
- **flagVF** (optional) = 0/1 to include/exclude volume fraction corrections in the long-range isotropic terms
18.38.2 Examples

```
pair_style brownian 1.5 1 2.0 2.5 2.0 5878567 (assuming radius = 1)
pair_coeff 1 1 2.05 2.8
pair_coeff * *
```

18.38.3 Description

Styles `brownian` and `brownian/poly` compute Brownian forces and torques on finite-size spherical particles. The former requires monodisperse spherical particles; the latter allows for polydisperse spherical particles.

These pair styles are designed to be used with either the `pair_style lubricate` or `pair_style lubricateU` commands to provide thermostatting when dissipative lubrication forces are acting. Thus the parameters `mu`, `flaglog`, `flagfld`, `cutinner`, and `cutoff` should be specified consistent with the settings in the lubrication pair styles. For details, refer to either of the lubrication pair styles.

The `t_target` setting is used to specify the target temperature of the system. The random number `seed` is used to generate random numbers for the thermostatting procedure.

The `flagHI` and `flagVF` settings are optional. Neither should be used, or both must be defined.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- `cutinner` (distance units)
- `cutoff` (distance units)

The two coefficients are optional. If neither is specified, the two cutoffs specified in the pair_style command are used. Otherwise both must be specified.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed in this section of the manual. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See this section of the manual for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I != J, the two cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the `pair_modify` shift option for the energy of the pair interaction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.
This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.38.4 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Only spherical monodisperse particles are allowed for pair_style brownian.

Only spherical particles are allowed for pair_style brownian/poly.

pair_coeff 1 1 100.0 1.5 200.0 9.0
```

18.55.3 Description

The *buck* style computes a Buckingham potential (exp/6 instead of Lennard-Jones 12/6) given by

\[ E = A e^{-r/p} - \frac{C}{r^6} \quad r < r_c \]

where \( p \) is an ionic-pair dependent length parameter, and \( r_c \) is the cutoff on both terms.

The styles with *coul/cut* or *coul/long* or *coul/msm* add a Coulombic term as described for the *lj/cut* pair styles. For *buck/coul/long* and *buck/coul/msm*, an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the *kspace_style* command and its *ewald* or *pppm* or *msm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.
If one cutoff is specified for the born/coul/cut and born/coul/long and born/coul/msm styles, it is used for both the A,C and Coulombic terms. If two cutoffs are specified, the first is used as the cutoff for the A,C terms, and the second is the cutoff for the Coulombic term.

Note that these potentials are related to the Born-Mayer-Huggins potential.

Note: For all these pair styles, the terms with A and C are always cutoff. The additional Coulombic term can be cutoff or long-range (no cutoff) depending on whether the style name includes coul/cut or coul/long or coul/msm. If you wish the C/r^6 term to be long-range (no cutoff), then see the pair_style buck/long/coul/long command.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- A (energy units)
- ρ (distance units)
- C (energy-distance^6 units)
- cutoff (distance units)
- cutoff2 (distance units)

The second coefficient, ρ, must be greater than zero. The coefficients A,:math:rho, and C can be written as analytical expressions of ε and σ, in analogy to the Lennard-Jones potential (Khrapak).

The latter 2 coefficients are optional. If not specified, the global A,C and Coulombic cutoffs are used. If only one cutoff is specified, it is used as the cutoff for both A,C and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the A,C and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style buck, since it has no Coulombic terms. For buck/coul/long only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual IJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

These pair styles do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

These styles support the pair_modify shift option for the energy of the exp() and 1/r^6 portion of the pair interaction.

The buck/coul/long pair style supports the pair_modify table option to tabulate the short-range portion of the long-range Coulombic interaction.

These styles support the pair_modify tail option for adding long-range tail corrections to energy and pressure for the A,C terms in the pair interaction.
These styles write their information to *binary restart files*, so **pair_style** and **pair_coeff** commands do not need to be specified in an input script that reads a restart file.

These styles can only be used via the *pair* keyword of the **run_style respa** command. They do not support the *inner*, *middle*, *outer* keywords.

### 18.55.4 Restrictions

The **buck/coul/long** style is part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

\end{verbatim}

18.57.3 Description

The `buck6d/coul/gauss` styles evaluate vdW and Coulomb interactions following the MOF-FF force field after *(Schmid)*. The vdW term of the `buck6d` styles computes a dispersion damped Buckingham potential:

\[ E = A e^{-\kappa r} - \frac{C}{r^6} \cdot \frac{1}{1 + D r^{14}} \quad r < r_c \]

where \( A \) and \( C \) are a force constant, \( \kappa \) is an ionic-pair dependent reciprocal length parameter, \( D \) is a dispersion correction parameter, and the cutoff \( r_c \) truncates the interaction distance. The first term in the potential corresponds to the Buckingham repulsion term and the second term to the dispersion attraction with a damping correction analog to the Grimme correction used in DFT. The latter corrects for artifacts occurring at short distances which become an issue for soft vdW potentials.

The `buck6d` styles include a smoothing function which is invoked according to the global smoothing parameter within the specified cutoff. Hereby a parameter of i.e. 0.9 invokes the smoothing within 90% of the cutoff. No smoothing is applied at a value of 1.0. For the `gauss/dsf` style this smoothing is only applicable for the dispersion damped Buckingham potential. For the `gauss/long` styles the smoothing function can also be invoked for the real space coulomb interactions which enforce continuous energies and forces at the cutoff.

Both styles `buck6d/coul/gauss/dsf` and `buck6d/coul/gauss/long` evaluate a Coulomb potential using spherical Gaussian type charge distributions which effectively dampen electrostatic interactions for high charges at close distances. The electrostatic potential is thus evaluated as:

\[ E = C \frac{q_i q_j}{\epsilon r_{ij}} \text{erf}(\alpha_{ij} r_{ij}) \quad r < r_c \]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, \( \epsilon \) is the dielectric constant which can be set by the `dielectric` command, \( \alpha \) is the ion pair dependent damping parameter and \( \text{erf}() \) is the error-function. The cutoff \( r_c \) truncates the interaction distance.

The style `buck6d/coul/gauss/dsf` computes the Coulomb interaction via the damped shifted force model described in *(Fennell)* approximating an Ewald sum similar to the `pair coul/dsf` styles. In `buck6d/coul/gauss/long` an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the `kspace_style` command and its `ewald` or `pppm` options. The Coulombic cutoff in this case separates the real and reciprocal space evaluation of the Ewald sum.

If one cutoff is specified it is used for both the vdW and Coulomb terms. If two cutoffs are specified, the first is used as the cutoff for the vdW terms, and the second is the cutoff for the Coulombic term.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- A (energy units)
- \( \rho \) (distance\(^{-1}\) units)
- C (energy-distance\(^6\) units)
- D (distance\(^{14}\) units)
• $\alpha$ (distance^{-1} units)
• cutoff (distance units)

The second coefficient, $\rho$, must be greater than zero. The latter coefficient is optional. If not specified, the global vdW cutoff is used.

Mixing, shift, table, tail correction, restart, rRESPA info:

These pair styles do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

These styles do not support the pair_modify shift option for the energy. Instead the smoothing function should be applied by setting the global smoothing parameter to a value < 1.0.

These styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

18.57.4 Restrictions

These styles are part of the USER-MOFFF package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

pair_coeff  *  * 1 1  
pair_coeff  1 1 1 3 4
```

18.59.3 Description

The `buck/long/coul/long` style computes a Buckingham potential (exp/6 instead of Lennard-Jones 12/6) and Coulombic potential, given by

\[
E = A e^{-r/\rho} - \frac{C}{r^6} \quad r < r_c
\]
\[
E = \frac{C q_i q_j}{r} \quad r < r_c
\]

\(r_c\) is the cutoff. If one cutoff is specified in the `pair_style` command, it is used for both the Buckingham and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the Buckingham and Coulombic terms respectively.

The purpose of this pair style is to capture long-range interactions resulting from both attractive 1/r^6 Buckingham and Coulombic 1/r interactions. This is done by use of the `flag_buck` and `flag_coul` settings. The Ismail paper has more details on when it is appropriate to include long-range 1/r^6 interactions, using this potential.

If `flag_buck` is set to `long`, no cutoff is used on the Buckingham 1/r^6 dispersion term. The long-range portion can be calculated by using the `kspace_style ewald/disp or pppm/disp` commands. The specified Buckingham cutoff then determines which portion of the Buckingham interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the Kspace style. If `flag_buck` is set to `cut`, the Buckingham interactions are simply cutoff, as with `pair_style buck`.

If `flag_coul` is set to `long`, no cutoff is used on the Coulombic interactions. The long-range portion can be calculated by using any of several `kspace_style` command options such as `pppm` or `ewald`. Note that if `flag_buck` is also set to long, then the `ewald/disp` or `pppm/disp` Kspace style needs to be used to perform the long-range calculations for both the Buckingham and Coulombic interactions. If `flag_coul` is set to `off`, Coulombic interactions are not computed.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- A (energy units)  
- rho (distance units)  
- C (energy-distance^6 units)  
- cutoff (distance units)  
- cutoff2 (distance units)

The second coefficient, rho, must be greater than zero.

The latter 2 coefficients are optional. If not specified, the global Buckingham and Coulombic cutoffs specified in the `pair_style` command are used. If only one cutoff is specified, it is used as the cutoff for both Buckingham and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the Buckingham and Coulombic cutoffs for this type pair. Note that if you are using `flag_buck` set to `long`, you cannot specify a Buckingham cutoff for an atom type pair, since only one global Buckingham cutoff is allowed. Similarly, if you are using `flag_coul` set to `long`, you cannot specify a Coulombic cutoff for an atom type pair, since only one global Coulombic cutoff is allowed.
Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

This pair styles does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This pair style supports the pair_modify shift option for the energy of the exp() and 1/r^6 portion of the pair interaction, assuming flag_buck is cut.

This pair style does not support the pair_modify shift option for the energy of the Buckingham portion of the pair interaction.

This pair style supports the pair_modify table and table/disp options since they can tabulate the short-range portion of the long-range Coulombic and dispersion interactions.

This pair style write its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the run_style command for details.

18.59.4 Restrictions

This style is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.76.3 Description

These pair styles compute Lennard Jones (LJ) and Coulombic interactions with additional switching or shifting functions that ramp the energy and/or force smoothly to zero between an inner and outer cutoff. They are implementations of the widely used CHARMM force field used in the CHARMM MD code (and others). See (MacKerell) for a description of the CHARMM force field.

The styles with charmm (not charmmfsw or charmmfsh) in their name are the older, original LAMMPS implementations. They compute the LJ and Coulombic interactions with an energy switching function (esw, shown in the formula below as $S(r)$), which ramps the energy smoothly to zero between the inner and outer cutoff. This can cause irregularities in pair-wise forces (due to the discontinuous second derivative of energy at the boundaries of the switching region), which in some cases can result in detectable artifacts in an MD simulation.

The newer styles with charmmfsw or charmmfsh in their name replace the energy switching with force switching (fsw) and force shifting (fsh) functions, for LJ and Coulombic interactions respectively. These follow the formulas and description given in (Steinbach) and (Brooks) to minimize these artifacts.

**Note:** The newer charmmfsw or charmmfsh styles were released in March 2017. We recommend they be used instead of the older charmm styles. This includes the newer dihedral_style charmmfsw command. Eventually code from the new styles will propagate into the related pair styles (e.g. implicit, accelerator, free energy variants).

**Note:** The newest CHARMM pair styles reset the Coulombic energy conversion factor used internally in the code, from the LAMMPS value to the CHARMM value, as if it were effectively a parameter of the force field. This is because the CHARMM code uses a slightly different value for the this conversion factor in real units (Kcal/mole), namely CHARMM = 332.0716, LAMMPS = 332.06371. This is to enable more precise agreement by LAMMPS with the CHARMM force field energies and forces, when using one of these two CHARMM pair styles.

$$
E = \begin{cases}
    LJ(r) & r < r_{in} \\
    S(r) \ast LJ(r) & r_{in} < r < r_{out} \\
    0 & r > r_{out}
\end{cases}
$$

$$
E = \begin{cases}
    C(r) & r < r_{in} \\
    S(r) \ast C(r) & r_{in} < r < r_{out} \\
    0 & r > r_{out}
\end{cases}
$$

$$
LJ(r) = 4\epsilon \left[ \frac{\sigma}{r} \right]^{12} - \left( \frac{\sigma}{r} \right)^{6}
$$

$$
C(r) = \frac{C_{q_i q_j}}{r}
$$

$$
S(r) = \left[ \frac{r_{out}^2 - r^2}{r_{out}^2} \right]^2 \left[ \frac{r_{out}^2 + 2r^2 - 3r_{in}^2}{r_{out}^2 - r_{in}^2} \right]^3
$$

where $S(r)$ is the energy switching function mentioned above for the charmm styles. See the (Steinbach) paper for the functional forms of the force switching and force shifting functions used in the charmmfsw and charmmfsh styles.

When using the lj/charmm/coul/charmm styles, both the LJ and Coulombic terms require an inner and outer cutoff. They can be the same for both formulas or different depending on whether 2 or 4 arguments are used in the pair_style command. For the lj/charmmfsw/coul/charmmfsh style, the LJ term requires both an inner and outer cutoff, while the Coulombic term requires only one cutoff. If the Coulombic cutoff is not specified (2 instead of 3 arguments), the LJ outer cutoff is used for the Coulombic cutoff. In all cases where an inner and outer cutoff are specified, the inner cutoff distance must be less than the outer cutoff. It is typical to make the difference between the inner and outer cutoffs about 2.0 Angstroms.
Style lj/charmm/coul/charmm/implicit computes the same formulas as style lj/charmm/coul/charmm except that an additional 1/r term is included in the Coulombic formula. The Coulombic energy thus varies as 1/r^2. This is effectively a distance-dependent dielectric term which is a simple model for an implicit solvent with additional screening. It is designed for use in a simulation of an unsolvated biomolecule (no explicit water molecules).

Styles lj/charmm/coul/long and lj/charmm/coul/msm compute the same formulas as style lj/charmm/coul/charmm and style lj/charmmfsw/coul/long computes the same formulas as style lj/charmmfsw/coul/charmmfsh, except that an additional damping factor is applied to the Coulombic term, so it can be used in conjunction with the kspace_style command and its ewald or pppm or msm option. Only one Coulombic cutoff is specified for these styles; if only 2 arguments are used in the pair_style command, then the outer LJ cutoff is used as the single Coulombic cutoff. The Coulombic cutoff specified for these styles means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- \( \epsilon_{14} \) (energy units)
- \( \sigma_{14} \) (distance units)

Note that \( \sigma \) is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at \( 2^{1/6} \sigma \).

The latter 2 coefficients are optional. If they are specified, they are used in the LJ formula between 2 atoms of these types which are also first and fourth atoms in any dihedral. No cutoffs are specified because the CHARMM force field does not allow varying cutoffs for individual atom pairs; all pairs use the global cutoff(s) specified in the pair_style command.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I ≠ J, the epsilon, sigma, epsilon_14, and sigma_14 coefficients for all of the lj/charmm pair styles can be mixed. The default mix value is arithmetic to coincide with the usual settings for the CHARMM force field. See the “pair_modify” command for details.

None of the lj/charmm or lj/charmmfsw pair styles support the pair_modify shift option, since the Lennard-Jones portion of the pair interaction is smoothed to 0.0 at the cutoff.

The lj/charmm/coul/long and lj/charmmfsw/coul/long styles support the pair_modify table option since they can tabulate the short-range portion of the long-range Coulombic interaction.
None of the lj/charmm or lj/charmmfsw pair styles support the pair_modify tail option for adding long-range tail corrections to energy and pressure, since the Lennard-Jones portion of the pair interaction is smoothed to 0.0 at the cutoff.

All of the lj/charmm and lj/charmmfsw pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/charmm/coul/long and lj/charmmfsw/coul/long pair styles support the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the pair keyword of run_style respa. See the run_style command for details.

### 18.76.4 Restrictions

All the styles with coul/charmm or coul/charmmfsh styles are part of the MOLECULE package. All the styles with coul/long style are part of the KSPACE package. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

18.87.3 Description

The `lj/class2` styles compute a 6/9 Lennard-Jones potential given by

\[
E = \epsilon \left[ 2 \left( \frac{\sigma}{r} \right)^9 - 3 \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c
\]

\(r_c\) is the cutoff.

The `lj/class2/coul/cut` and `lj/class2/coul/long` styles add a Coulombic term as described for the `lj/cut` pair styles.

See (Sun) for a description of the COMPASS class2 force field.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- \(\epsilon\) (energy units)
- \(\sigma\) (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global class 2 and Coulombic cutoffs are used. If only one cutoff is specified, it is used as the cutoff for both class 2 and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the class 2 and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style `lj/class2`, since it has no Coulombic terms.

For `lj/class2/coul/long` only the class 2 cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the `pair_style` command.

If the `pair_coeff` command is not used to define coefficients for a particular I \(!= J\) type pair, the mixing rule for \(\epsilon\) and \(\sigma\) for all class2 potentials is to use the sixthpower formulas documented by the `pair_modify` command. The `pair_modify mix` setting is thus ignored for class2 potentials for epsilon and sigma. However it is still followed for mixing the cutoff distance.
A version of these styles with a soft core, \textit{lj/cut/soft}, suitable for use in free energy calculations, is part of the \textit{USER-FEP} package and is documented with the \texttt{pair_style */soft} styles. The version with soft core is only available if LAMMPS was built with that package. See the \texttt{Build package} doc page for more info.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, \textit{USER-INTEL}, KOKKOS, \textit{USER-OMP} and \textit{OPT} packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} \texttt{command-line switch} when you invoke LAMMPS, or you can use the \texttt{suffix} \texttt{command} in your input script.

See the \texttt{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

For atom type pairs I,J and I \neq J, the epsilon and sigma coefficients and cutoff distance for all of the \texttt{lj/class2} pair styles can be mixed. Epsilon and sigma are always mixed with the value \texttt{sixthpower}. The cutoff distance is mixed by whatever option is set by the \texttt{pair_modify} command (default = geometric). See the “\texttt{pair_modify}” command for details.

All of the \texttt{lj/class2} pair styles support the \texttt{pair_modify} \texttt{shift} option for the energy of the Lennard-Jones portion of the pair interaction.

The \texttt{lj/class2/coul/long} pair style does not support the \texttt{pair_modify} \texttt{table} option since a tabulation capability has not yet been added to this potential.

All of the \texttt{lj/class2} pair styles support the \texttt{pair_modify} \texttt{tail} option for adding a long-range tail correction to the energy and pressure of the Lennard-Jones portion of the pair interaction.

All of the \texttt{lj/class2} pair styles write their information to \texttt{binary restart files}, so \texttt{pair_style} and \texttt{pair_coeff} commands do not need to be specified in an input script that reads a restart file.

Only the \texttt{lj/class2} and \texttt{lj/class2/coul/long} pair styles support the use of the \texttt{inner}, \texttt{middle}, and \texttt{outer} keywords of the \texttt{run_style respa} command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the \texttt{pair} keyword of \texttt{run_style respa}. See the \texttt{run_style} command for details.

**18.87.4 Restrictions**

These styles are part of the \texttt{CLASS2} package. They are only enabled if LAMMPS was built with that package. See the \texttt{Build package} doc page for more info.

**18.87.5 Related commands**

\texttt{pair_coeff}, \texttt{pair_style */soft}

**Default:** none

18.88 pair_style colloid command

18.89 pair_style colloid/gpu command

18.90 pair_style colloid/omp command

18.90.1 Syntax

```plaintext
pair_style colloid cutoff
```

- `cutoff` = global cutoff for colloidal interactions (distance units)

18.90.2 Examples

```plaintext
pair_style colloid 10.0
pair_coeff * * 25 1.0 10.0 10.0
pair_coeff 1 1 144 1.0 0.0 0.0 3.0
pair_coeff 1 2 75.398 1.0 0.0 10.0 9.0
pair_coeff 2 2 39.478 1.0 10.0 10.0 25.0
```

18.90.3 Description

Style `colloid` computes pairwise interactions between large colloidal particles and small solvent particles using 3 formulas. A colloidal particle has a size > sigma; a solvent particle is the usual Lennard-Jones particle of size sigma.

The colloidal-colloid interaction energy is given by

\[
U_A = -\frac{A_{cc}}{6} \left[ \frac{2a_1a_2}{r^2 - (a_1 + a_2)^2} + \frac{2a_1a_2}{r^2 - (a_1 - a_2)^2} + \ln \left( \frac{r^2 - (a_1 + a_2)^2}{r^2 - (a_1 - a_2)^2} \right) \right]
\]

\[
U_R = \frac{A_{cc}}{37800} \frac{\sigma^6}{r} \left[ \frac{r^2 - 7r(a_1 + a_2) + 6(a_1^2 + 7a_1a_2 + a_2^2)}{(r - a_1 - a_2)^7} + \frac{r^2 + 7r(a_1 + a_2) + 6(a_1^2 + 7a_1a_2 + a_2^2)}{(r + a_1 + a_2)^7} - \frac{r^2 + 7r(a_1 - a_2) + 6(a_1^2 - 7a_1a_2 + a_2^2)}{(r + a_1 - a_2)^7} - \frac{r^2 - 7r(a_1 - a_2) + 6(a_1^2 - 7a_1a_2 + a_2^2)}{(r - a_1 + a_2)^7} \right]
\]

\[U = U_A + U_R, \quad r < r_c\]

where \(A_{cc}\) is the Hamaker constant, \(a_1\) and \(a_2\) are the radii of the two colloidal particles, and \(r_c\) is the cutoff. This equation results from describing each colloidal particle as an integrated collection of Lennard-Jones particles of size sigma and is derived in (Everaers).
The colloid-solvent interaction energy is given by

\[ U = \frac{2 a^3 \sigma^3 A_{cs}}{9 (a^2 - r^2)^3} \left[ 1 - \frac{(5 a^6 + 45 a^4 r^2 + 63 a^2 r^4 + 15 r^6) \sigma^6}{15 (a - r)^6 (a + r)^6} \right], \quad r < r_c \]

where :math:`A_{cs}` is the Hamaker constant, :math:`a` is the radius of the colloidal particle, and :math:`r_c` is the cutoff. This formula is derived from the colloid-colloid interaction, letting one of the particle sizes go to zero.

The solvent-solvent interaction energy is given by the usual Lennard-Jones formula

\[ U = \frac{A_{ss}}{36} \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right], \quad r < r_c \]

with :math:`A_{ss}` set appropriately, which results from letting both particle sizes go to zero.

When used in combination with `pair_style yukawa/colloid`, the two terms become the so-called DLVO potential, which combines electrostatic repulsion and van der Waals attraction.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- A (energy units)
- \( \sigma \) (distance units)
- d1 (distance units)
- d2 (distance units)
- cutoff (distance units)

A is the Hamaker energy prefactor and should typically be set as follows:

- \( A_{cc} = \text{colloid/colloid} = 4 \pi^2 = 39.5 \)
- \( A_{cs} = \text{colloid/solvent} = \sqrt{A_{cc}A_{ss}} \)
- \( A_{ss} = \text{solvent/solvent} = 144 \) (assuming epsilon = 1, so that 144/36 = 4)

\( \sigma \) is the size of the solvent particle or the constituent particles integrated over in the colloidal particle and should typically be set as follows:

- \( \sigma_{cc} = \text{colloid/colloid} = 1.0 \)
- \( \sigma_{cs} = \text{colloid/solvent} = \text{arithmetic mixing between colloid } \sigma \text{ and solvent } \sigma \)
- \( \sigma_{ss} = \text{solvent/solvent} = 1.0 \) or whatever size the solvent particle is

Thus typically \( \sigma_{cs} = 1.0 \), unless the solvent particle’s size != 1.0.

D1 and d2 are particle diameters, so that \( d1 = 2*a1 \) and \( d2 = 2*a2 \) in the formulas above. Both d1 and d2 must be values >= 0. If \( d1 > 0 \) and \( d2 > 0 \), then the pair interacts via the colloid-colloid formula above. If \( d1 = 0 \) and \( d2 = 0 \), then the pair interacts via the solvent-solvent formula. I.e. a d value of 0 is a Lennard-Jones particle of size \( \sigma \). If either \( d1 = 0 \) or \( d2 = 0 \) and the other is larger, then the pair interacts via the colloid-solvent formula.

Note that the diameter of a particular particle type may appear in multiple pair_coeff commands, as it interacts with other particle types. You should insure the particle diameter is specified consistently each time it appears.

The last coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used. However, you typically want different cutoffs for interactions between different particle sizes. E.g. if colloidal particles of diameter 10 are used with solvent particles of diameter 1, then a solvent-solvent cutoff of 2.5 would correspond to a colloid-colloid cutoff of 25. A good rule-of-thumb is to use a colloid-solvent cutoff that is half the big diameter + 4 times the small diameter. I.e. 9 = 5 + 4 for the colloid-solvent cutoff in this case.
Note: When using pair_style colloid for a mixture with 2 (or more) widely different particles sizes (e.g. sigma=10 colloids in a background sigma=1 LJ fluid), you will likely want to use these commands for efficiency: neighbor multi and comm_modify multi.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I and J and I != J, the A, sigma, d1, and d2 coefficients and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. D1 and d2 are distance values and are mixed like sigma. The default mix value is `geometric`. See the “pair_modify” command for details.

This pair style supports the `pair_modify` shift option for the energy of the pair interaction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

18.90.4 Restrictions

This style is part of the COLLOID package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Normally, this pair style should be used with finite-size particles which have a diameter, e.g. see the `atom_style sphere` command. However, this is not a requirement, since the only definition of particle size is via the `pair_coeff` parameters for each type. In other words, the physical radius of the particle is ignored. Thus you should insure that the d1,d2 parameters you specify are consistent with the physical size of the particles of that type.

Per-particle polydispersity is not yet supported by this pair style; only per-type polydispersity is enabled via the `pair_coeff` parameters.

\]
\[
\text{pair_coeff } * * \ldots/\text{potentials/ffield.comb3 } \text{O } \text{Cu } \text{N } \text{C } \text{O}
\]

18.93.3 Description

Style \textit{comb} computes the second generation variable charge COMB (Charge-Optimized Many-Body) potential. Style \textit{comb3} computes the third-generation COMB potential. These COMB potentials are described in \textit{(COMB)} and \textit{(COMB3)}. Briefly, the total energy \( E_T \) of a system of atoms is given by

\[
E_T = \sum_i [E_i^{self}(q_i) + \sum_{j>i} [E_{ij}^{short}(r_{ij}, q_i, q_j) + E_{ij}^{Coul}(r_{ij}, q_i, q_j)] + E^{polar}(q_i, r_{ij}) + E^{vdW}(r_{ij}) + E^{barr}(q_i) + E^{corr}(r_{ij}, \theta_{jik})]
\]

where \( E_i^{self} \) is the self-energy of atom \( i \) (including atomic ionization energies and electron affinities), \( E_{ij}^{short} \) is the bond-order potential between atoms \( i \) and \( j \), \( E_{ij}^{Coul} \) is the Coulomb interactions, \( E^{polar} \) is the polarization term for organic systems (style \textit{comb3} only), \( E^{vdW} \) is the van der Waals energy (style \textit{comb3} only), \( E^{barr} \) is a charge barrier function, and \( E^{corr} \) are angular correction terms.
The COMB potentials (styles `comb` and `comb3`) are variable charge potentials. The equilibrium charge on each atom is calculated by the electronegativity equalization (QEq) method. See `Rick` for further details. This is implemented by the `fix qeq/comb` command, which should normally be specified in the input script when running a model with the COMB potential. The `fix qeq/comb` command has options that determine how often charge equilibration is performed, its convergence criterion, and which atoms are included in the calculation.

Only a single pair_coeff command is used with the `comb` and `comb3` styles which specifies the COMB potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the potential file in the pair_coeff command, where N is the number of LAMMPS atom types.

For example, if your LAMMPS simulation of a Si/SiO2/ HfO2 interface has 4 atom types, and you want the first and last to be Si, the second to be Hf, and the third to be O, and you would use the following pair_coeff command:

```
pair_coeff * * ../potentials/ffield.comb Si Hf O Si
```

The first two arguments must be `* *` so as to span all LAMMPS atom types. The first and last Si arguments map LAMMPS atom types 1 and 4 to the Si element in the `ffield.comb` file. The second Hf argument maps LAMMPS atom type 2 to the Hf element, and the third O argument maps LAMMPS atom type 3 to the O element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a `comb` potential is used as part of the `hybrid` pair style. The NULL values are placeholders for atom types that will be used with other potentials.

For style `comb`, the provided potential file `ffield.comb` contains all currently-available second generation COMB parameterizations: for Si, Cu, Hf, Ti, O, their oxides and Zr, Zn and U metals. For style `comb3`, the potential file `ffield.comb3` contains all currently-available third generation COMB parameterizations: O, Cu, N, C, H, Ti, Zn and Zr. The status of the optimization of the compounds, for example Cu2O, TiN and hydrocarbons, are given in the following table:

<table>
<thead>
<tr>
<th></th>
<th>O</th>

<td>P</td>
<td>P</td>
<td>F</td>
</tr>
</tbody>
</table>

- `F` = Fully optimized
- `M` = Only optimized for dimer molecule
- `P` = in progress, but have it from mixing rule

For style `comb3`, in addition to `ffield.comb3`, a special parameter file, `lib.comb3`, that is exclusively used for C/O/H systems, will be automatically loaded if carbon atom is detected in LAMMPS input structure. This file must be in your working directory or in the directory pointed to by the environment variable LAMMPS_POTENTIALS, as described on the `pair_coeff` command doc page.

Keyword `polar` indicates whether the force field includes the atomic polarization. Since the equilibration of the polarization has not yet been implemented, it can only set `polar_off` at present.

**Note:** You cannot use potential file `ffield.comb` with style `comb3`, nor file `ffield.comb3` with style `comb`.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages`
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

These pair styles does not support the pair_modify shift, table, and tail options.

These pair styles do not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style, pair_coeff, and fix qeq/comb commands in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.93.4 Restrictions

These pair styles are part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair styles requires the newton setting to be “on” for pair interactions.

The COMB potentials in the ffield.comb and ffield.comb3 files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the COMB potential with any LAMMPS units, but you would need to create your own COMB potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

18.93.5 Related commands

pair_style, pair_coeff, fix qeq/comb

Default: none

18.94 pair_style cosine/squared command

18.94.1 Syntax

```
pair_style cosine/squared cutoff

• cutoff = global cutoff for cosine-squared interactions (distance units)
```

```
pair_coeff i j eps sigma
pair_coeff i j eps sigma cutoff
pair_coeff i j eps sigma wca
pair_coeff i j eps sigma cutoff wca
```

• i,j = a particle type
• eps = interaction strength, i.e. the depth of the potential minimum (energy units)
• sigma = distance of the potential minimum from 0
• cutoff = the cutoff distance for this pair type, if different from global (distance units)
• wca = if specified a Weeks-Chandler-Andersen potential (with eps strength and minimum at sigma) is added, otherwise not

18.94.2 Examples

```
pair_style cosine/squared 3.0
pair_coeff * * 1.0 1.3
pair_coeff 1 3 1.0 1.3 2.0
pair_coeff 1 3 1.0 1.3 wca
pair_coeff 1 3 1.0 1.3 2.0 wca
```

18.94.3 Description

Style *cosine/squared* computes a potential of the form

\[
E = \begin{cases} 
-\epsilon & r < \sigma \\
-\epsilon \cos \left( \frac{\pi (r-\sigma)}{2(r_c-\sigma)} \right)^2 & \sigma \leq r < r_c \\
0 & r \geq r_c 
\end{cases}
\]

between two point particles, where \((\sigma, -\epsilon)\) is the location of the (rightmost) minimum of the potential, as explained in the syntax section above.

This potential was first used in (Cooke)\_\#CKD for a coarse-grained lipid membrane model. It is generally very useful as a non-specific interaction potential because it is fully adjustable in depth and width while joining the minimum at (sigma, -epsilon) and zero at (cutoff, 0) smoothly, requiring no shifting and causing no related artifacts, tail energy calculations etc. This evidently requires cutoff to be larger than sigma.

If the *wca* option is used then a Weeks-Chandler-Andersen potential (Weeks)\_\#WCA is added to the above specified cosine-squared potential, specifically the following:

\[
E = \epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - 2 \left( \frac{\sigma}{r} \right)^{6} + 1 \right], \quad r < \sigma
\]
In this case, and this case only, the $\sigma$ parameter can be equal to cutoff ($\sigma = \text{cutoff}$) which will result in ONLY the WCA potential being used (and print a warning), so the minimum will be attained at $(\text{sigma}, 0)$. This is a convenience feature that enables a purely repulsive potential to be used without a need to define an additional pair style and use the hybrid styles.

The energy and force of this pair style for parameters $\epsilon = 1.0$, $\sigma = 1.0$, $\text{cutoff} = 2.5$, with and without the WCA potential, are shown in the graphs below:

![Graphs showing energy and force with and without WCA potential](image)

**Mixing, shift, table, tail correction, restart, rRESPA info:**

Mixing is not supported for this style.

The *shift*, *table* and *tail* options are not relevant for this style.

This pair style writes its information to binary restart files, so *pair_style* and *pair_coeff* commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

**18.94.4 Restrictions**

The *cosine/squared* style is part of the “USER-MISC” package. It is only enabled if LAMMPS is build with that package. See the *Build package* doc page for more info.

18.120.3 Description

The **coul/cut** style computes the standard Coulombic interaction potential given by

\[ E = \frac{C q_i q_j}{\epsilon r} \quad r < r_c \]

where \( C \) is an energy-conversion constant, \( Q_i \) and \( Q_j \) are the charges on the 2 atoms, and \( \epsilon \) is the dielectric constant which can be set by the *dielectric* command. The cutoff \( r_c \) truncates the interaction distance.

Style **coul/debye** adds an additional \( \exp() \) damping factor to the Coulombic term, given by

\[ E = \frac{C q_i q_j}{\epsilon r} \exp(-\kappa r) \quad r < r_c \]

where \( \kappa \) is the Debye length. This potential is another way to mimic the screening effect of a polar solvent.

Style **coul/dsf** computes Coulombic interactions via the damped shifted force model described in Fennell, given by:

\[ E = q_i q_j \left[ \frac{\text{erfc}(\alpha r)}{r} - \frac{\text{erfc}(\alpha r_c)}{r_c} + \left( \frac{\text{erfc}(\alpha r_c)}{r_c^2} + \frac{2\alpha \exp(-\alpha^2 r_c^2)}{\sqrt{\pi} r_c} \right) (r - r_c) \right] \quad r < r_c \]

where \( \alpha \) is the damping parameter and \( \text{erfc()} \) is the complementary error-function. The potential corrects issues in the Wolf model (described below) to provide consistent forces and energies (the Wolf potential is not differentiable at the cutoff) and smooth decay to zero.

Style **coul/wolf** computes Coulombic interactions via the Wolf summation method, described in Wolf, given by:

\[ E_i = \frac{1}{2} \sum_{j \neq i} q_i q_j \text{erfc}(\alpha r_{ij}) \frac{1}{r_{ij}} + \frac{1}{2} \sum_{j \neq i} q_i q_j \text{erf}(\alpha r_{ij}) \frac{1}{r_{ij}} \quad r < r_c \]

where \( \alpha \) is the damping parameter, and \( \text{erf()} \) and \( \text{erfc()} \) are error-function and complementary error-function terms. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise \( 1/r \) summation. With a manipulation of adding and subtracting a self term (for \( i = j \)) to the first and second term on the right-hand-side, respectively, and a small enough \( \alpha \) damping parameter, the second term shrinks and the potential becomes a rapidly-converging real-space summation. With a long enough cutoff and small enough \( \alpha \) parameter, the energy and forces calculated by the Wolf summation method approach those of the Ewald sum. So it is a means of getting effective long-range interactions with a short-range potential.

Style **coul/streitz** is the Coulomb pair interaction defined as part of the Streitz-Mintmire potential, as described in *this paper*, in which charge distribution about an atom is modeled as a Slater 1s orbital. More details can be found in the referenced paper. To fully reproduce the published Streitz-Mintmire potential, which is a variable charge potential, style **coul/streitz** must be used with *pair_style eam/alloy* (or some other short-range potential that has been parameterized appropriately) via the *pair_style hybrid/overlay* command. Likewise, charge equilibration must be performed via the *fix qeq/slater* command. For example:

```
pair_style hybrid/overlay coul/streitz 12.0 wolf 0.31 eam/alloy
pair_coeff * * coul/streitz AlO.streitz Al O
pair_coeff * * eam/alloy AlO.eam.alloy Al O
fix 1 all qeq/slater 1 12.0 1.0e-6 100 coul/streitz
```

The keyword **wolf** in the **coul/streitz** command denotes computing Coulombic interactions via Wolf summation. An additional damping parameter is required for the Wolf summation, as described for the **coul/wolf** potential above. Alternatively, Coulombic interactions can be computed via an Ewald summation. For example:
Keyword *ewald* does not need a damping parameter, but a *kspace_style* must be defined, which can be style *ewald* or *pppm*. The Ewald method was used in Streitz and Mintmire's original paper, but a Wolf summation offers a speed-up in some cases.

For the fix *qeq/slater* command, the *qfile* can be a filename that contains QEq parameters as discussed on the *fix qeq* command doc page. Alternatively *qfile* can be replaced by “coul/streitz”, in which case the fix will extract QEq parameters from the coul/streitz pair style itself.

See the examples/strietz directory for an example input script that uses the Streitz-Mintmire potential. The potentials directory has the AlO.eam.alloy and AlO.streitz potential files used by the example.

Note that the Streiz-Mintmire potential is generally used for oxides, but there is no conceptual problem with extending it to nitrides and carbides (such as SiC, TiN). Pair coul/strietz used by itself or with any other pair style such as EAM, MEAM, Tersoff, or LJ in hybrid/overlay mode. To do this, you would need to provide a Streitz-Mintmire parameterization for the material being modeled.

Styles *coul/long* and *coul/msm* compute the same Coulombic interactions as style *coul/cut* except that an additional damping factor is applied so it can be used in conjunction with the *kspace_style* command and its *ewald* or *pppm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

Styles *tip4p/cut* and *tip4p/long* implement the Coulomb part of the TIP4P water model of (Jorgensen), which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as pair_style arguments. Style *tip4p/cut* uses a global cutoff for Coulomb interactions; style *tip4p/long* is for use with a long-range Coulombic solver (Ewald or PPPM).

**Note:** For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

See the *Howto tip4p* doc page for more information on how to use the TIP4P pair styles and lists of parameters to set. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance 2*qdist when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff >= Coulombic cutoff + 2*qdist, to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

Note that these potentials are designed to be combined with other pair potentials via the *pair_style hybrid/overlay* command. This is because they have no repulsive core. Hence if they are used by themselves, there will be no repulsion to keep two oppositely charged particles from moving arbitrarily close to each other.

The following coefficients must be defined for each pair of atom types via the *pair_coeff* command as in the examples above, or in the data or restart files read by the *read_data* or *read_restart* commands, or by mixing as described below:

- cutoff (distance units)

For *coul/cut* and *coul/debye*, the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the pair_style command is used.

For *coul/long* and *coul/msm* no cutoff can be specified for an individual IJ type pair via the pair_coeff command. All type pairs use the same global Coulomb cutoff specified in the pair_style command.
Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script. See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

\textbf{Mixing, shift, table, tail correction, restart, rRESPA info:}

For atom type pairs IJ and I \neq J, the cutoff distance for the \texttt{coul/cut} style can be mixed. The default mix value is \textit{geometric}. See the “pair_modify” command for details.

The \texttt{pair_modify} shift option is not relevant for these pair styles.

The \texttt{coul/long} style supports the \texttt{pair_modify} table option for tabulation of the short-range portion of the long-range Coulombic interaction.

These pair styles do not support the \texttt{pair_modify} tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to \textit{binary restart files}, so \texttt{pair_style} and \texttt{pair_coeff} commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the \texttt{pair} keyword of the \textit{run_style respa} command. They do not support the \texttt{inner}, \texttt{middle}, \texttt{outer} keywords.

\section*{18.120.4 Restrictions}

The \texttt{coul/long}, \texttt{coul/msm} and \texttt{tip4p/long} styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

\section*{18.120.5 Related commands}

\texttt{pair_coeff}, \texttt{pair_style}, \texttt{hybrid/overlay}, \texttt{kspace_style}

\textbf{Default:} none

18.121 pair_style coul/diel command

18.122 pair_style coul/diel/omp command

18.122.1 Syntax

```
pair_style coul/diel cutoff
```
cutoff = global cutoff (distance units)

18.122.2 Examples

```
pair_style coul/diel 3.5
pair_coeff 1 4 78. 1.375 0.112
```

18.122.3 Description

Style `coul/diel` computes a Coulomb correction for implicit solvent ion interactions in which the dielectric permittivity is distance dependent. The dielectric permittivity $\epsilon_D(r)$ connects to limiting regimes: One limit is defined by a small dielectric permittivity (close to vacuum) at or close to contact separation between the ions. At larger separations the dielectric permittivity reaches a bulk value used in the regular Coulomb interaction `coul/long` or `coul/cut`. The transition is modeled by a hyperbolic function which is incorporated in the Coulomb correction term for small ion separations as follows

$$E = C q_i q_j \left( \frac{\epsilon}{\epsilon_D(r)} - 1 \right) \quad r < r_e$$

$$\epsilon_D(r) = \frac{5.2 + \epsilon}{2} + \frac{\epsilon - 5.2}{2} \tanh \left( \frac{r - r_{me}}{\sigma_e} \right)$$

where $r_{me}$ is the inflection point of $\epsilon_D(r)$ and $\sigma_e$ is a slope defining length scale. $C$ is the same Coulomb conversion factor as in the pair_styles `coul/cut`, `coul/long`, and `coul/debye`. In this way the Coulomb interaction between ions is corrected at small distances $r$. The lower limit of $\epsilon_D(r->0)=5.2$ due to dielectric saturation (Stiles) while the Coulomb interaction reaches its bulk limit by setting $\epsilon_D(r \to \infty) = \epsilon$, the bulk value of the solvent which is 78 for water at 298K.

Examples of the use of this type of Coulomb interaction include implicit solvent simulations of salt ions (Lenart) and of ionic surfactants (Jusufi). Note that this potential is only reasonable for implicit solvent simulations and in combination with `coul/cut` or `coul/long`. It is also usually combined with gauss/cut, see (Lenart) or (Jusufi).

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $\epsilon$ (no units)
- $r_{me}$ (distance units)
- $\sigma_e$ (distance units)

The global cutoff ($r_c$) specified in the `pair_style` command is used.

Mixing, shift, table, tail correction, restart, rRESPA info:
This pair style does not support parameter mixing. Coefficients must be given explicitly for each type of particle pairs. This pair style supports the `pair_modify` shift option for the energy of the Gauss-potential portion of the pair interaction. The `pair_modify` table option is not relevant for this pair style. This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure. This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 18.122.4 Restrictions

This style is part of the “USER-MISC” package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

### 18.122.5 Related commands

`pair_coeff pair_style gauss/cut`

**Default:** none

### 18.123 pair_style coul/shield command

#### 18.123.1 Syntax

```
pair_style coul/shield cutoff tap_flag
```

- `cutoff` = global cutoff (distance units)
- `tap_flag` = 0/1 to turn off/on the taper function

#### 18.123.2 Examples

```
pair_style coul/shield 16.0 1
pair_coeff 1 2 0.70
```
18.123.3 Description

Style `coul/shield` computes a Coulomb interaction for boron and nitrogen atoms located in different layers of hexagonal boron nitride. This potential is designed be used in combination with the pair style `ilp/graphene/hbn`.

**Note:** This potential is intended for electrostatic interactions between two different layers of hexagonal boron nitride. Therefore, to avoid interaction within the same layers, each layer should have a separate molecule id and is recommended to use the “full” atom style, so that charge and molecule ID information is included.

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \\
V_{ij} = \text{Tap}(r_{ij}) \left( \frac{\kappa q_i q_j}{\sqrt{r_{ij}^2 + (1/\lambda_{ij})^3}} \right)
\]

\[
\text{Tap}(r_{ij}) = 20 \left( \frac{r_{ij}}{R_{\text{cut}}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{\text{cut}}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{\text{cut}}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{\text{cut}}} \right)^4 + 1
\]

Where \( \text{Tap}(r_{ij}) \) is the taper function which provides a continuous cutoff (up to third derivative) for inter-atomic separations larger than \( r_c \) (Leven1), (Leven2) and (Maaravi). Here \( \lambda \) is the shielding parameter that eliminates the short-range singularity of the classical mono-polar electrostatic interaction expression (Maaravi).

The shielding parameter \( \lambda \) (1/distance units) must be defined for each pair of atom types via the `pair_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands.

The global cutoff \( (r_c) \) specified in the `pair_style` command is used.

Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support parameter mixing. Coefficients must be given explicitly for each type of particle pairs.

The `pair_modify table` option is not relevant for this pair style.

This pair style does not support the `pair_modify tail` option for adding long-range tail corrections to energy and pressure.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

18.123.4 Restrictions

This style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.
18.123.5 Related commands

Pair_coeff pair_style ilp/graphene/hbn

Default: tap_flag = 1

18.124 pair_style coul/slater/cut command

18.125 pair_style coul/slater/long command

18.125.1 Syntax

pair_style coul/slater/cut lambda cutoff
pair_style coul/slater/long lambda cutoff

lambda = decay length of the charge (distance units) cutoff = cutoff (distance units)

18.125.2 Examples

pair_style coul/slater/cut 1.0 3.5
pair_coeff * *
pair_coeff 2 2 2.5
pair_style coul/slater/long 1.0 12.0
pair_coeff * *
pair_coeff 1 1 5.0

18.125.3 Description

Styles coul/slater compute electrostatic interactions in mesoscopic models which employ potentials without explicit excluded-volume interactions. The goal is to prevent artificial ionic pair formation by including a charge distribution in the Coulomb potential, following the formulation of (Melchor):

\[ E = \frac{C q_i q_j}{\epsilon r} \left( 1 - \left( 1 + \frac{r_{ij}}{\lambda} \exp \left( -\frac{2r_{ij}}{\lambda} \right) \right) \right) \quad r < r_c \]

where \( r_c \) is the cutoff distance and \( \lambda \) is the decay length of the charge. \( C \) is the same Coulomb conversion factor as in the pair_styles coul/cut and coul/long. In this way the Coulomb interaction between ions is corrected at small distances \( r \). For the coul/slater/cut style, the potential energy for distances larger than the cutoff is zero, while for the coul/slater/long, the long-range interactions are computed either by the Ewald or the PPPM technique.

Phenomena that can be captured at a mesoscopic level using this type of electrostatic interactions include the formation of polyelectrolyte-surfactant aggregates, charge stabilization of colloidal suspensions, and the formation of complexes driven by charged species in biological systems. (Vaiwala).
The cutoff distance is optional. If it is not used, the default global value specified in the pair_style command is used. For each pair of atom types, a specific cutoff distance can be defined via the pair_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( r_c \) (distance units)

The global decay length of the charge (\( \lambda \)) specified in the pair_style command is used for all pairs.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

For atom type pairs I,J and I \( \neq \) J, the cutoff distance for the coul/slater styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

The pair_modify shift and table options are not relevant for these pair styles.

These pair styles do not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

### 18.125.4 Restrictions

The coul/slater/long style requires the long-range solvers included in the KSPACE package.

These styles are part of the “USER-MISC” package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.136.3 Description

These pair styles are designed to be used with the adiabatic core/shell model of (Mitchell and Finchham). See the Howto coreshell doc page for an overview of the model as implemented in LAMMPS.

All the styles are identical to the corresponding pair style without the “/cs” in the name:

- pair_style born/coul/dsf
- pair_style born/coul/long
- pair_style born/coul/wolf
- pair_style buck/coul/long
- pair_style coul/long
- pair_style coul/wolf
- pair_style lj/cut/coul/long
- pair_style lj/class2/coul/long

except that they correctly treat the special case where the distance between two charged core and shell atoms in the same core/shell pair approach r = 0.0.

Styles with a “/long” in the name are used with a long-range solver for Coulombic interactions via the kspace_style command. They require special treatment of the short-range Coulombic interactions within the cor/shell model.

Specifically, the short-range Coulomb interaction between a core and its shell should be turned off using the special_bonds command by setting the 1-2 weight to 0.0, which works because the core and shell atoms are bonded to each other. This induces a long-range correction approximation which fails at small distances (~< 10e-8). Therefore, the Coulomb term which is used to calculate the correction factor is extended by a minimal distance (r_min = 1.0-6) when the interaction between a core/shell pair is treated, as follows

\[ E = \frac{Cq_i q_j}{\epsilon(r + r_{\text{min}})} \quad r \to 0 \]

where C is an energy-conversion constant, q_i and q_j are the charges on the core and shell, epsilon is the dielectric constant and r_{\text{min}} is the minimal distance.

For styles that are not used with a long-range solver, i.e. those with “/dsf” or “/wolf” in the name, the only correction is the addition of a minimal distance to avoid the possible r = 0.0 case for a core/shell pair.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

See the corresponding doc pages for pair styles without the “cs” suffix to see how mixing, shifting, tabulation, tail correction, restarting, and rRESPA are handled by these pair styles.
18.136.4 Restrictions

These pair styles are part of the CORESHELL package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

### 18.145.3 Description

Style *lj/cut/dipole/cut* computes interactions between pairs of particles that each have a charge and/or a point dipole moment. In addition to the usual Lennard-Jones interaction between the particles ($E_{LJ}$) the charge-charge ($E_{QQ}$), charge-dipole ($E_{QP}$), and dipole-dipole ($E_{PP}$) interactions are computed by these formulas for the energy ($E$), force...
(F), and torque (T) between particles I and J.

\[ E_{LJ} = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \]

\[ E_{qq} = \frac{q_i q_j}{r} \]

\[ E_{qp} = \frac{q}{r^3} (p \cdot r) \]

\[ E_{pp} = \frac{1}{r^3} (p_i \cdot p_j) - 3 \frac{3}{r^5} (p_i \cdot r)(p_j \cdot r) \]

\[ F_{qq} = \frac{q_i q_j}{r^3} r \]

\[ F_{qp} = -\frac{q}{r^5} p + 3\frac{q}{r^5} (p \cdot r)p \]

\[ F_{pp} = 3 \frac{3}{r^7} (p_i \cdot p_j) r - 15 \frac{3}{r^5} (p_i \cdot r)(p_j \cdot r)r + 3 \frac{3}{r^5} [(p_j \cdot r)p_i + (p_i \cdot r)p_j] \]

\[ T_{pq} = T_{ij} = \frac{q_i}{r} (p_i \times r) \]

\[ T_{qp} = T_{ji} = -\frac{q_i}{r} (p_j \times r) \]

\[ T_{pp} = T_{ij} = -\frac{1}{r^3} (p_i \times p_j) + \frac{3}{r^5} (p_j \cdot r)(p_i \times r) \]

\[ T_{pq} = T_{ji} = -\frac{1}{r^3} (p_j \times p_i) + \frac{3}{r^5} (p_i \cdot r)(p_j \times r) \]

where \( q_i \) and \( q_j \) are the charges on the two particles, \( p_i \) and \( p_j \) are the dipole moment vectors of the two particles, \( r \) is their separation distance, and the vector \( r = R_i - R_j \) is the separation vector between the two particles. Note that \( E_{qq} \) and \( F_{qq} \) are simply Coulombic energy and force, \( F_{ij} = -F_{ji} \) as symmetric forces, and \( T_{ij} \neq -T_{ji} \) since the torques do not act symmetrically. These formulas are discussed in (Allen) and in (Toukmaji).

Also note, that in the code, all of these terms (except \( E_{LJ} \)) have a \( C/\epsilon \) prefactor, the same as the Coulombic term in the LJ + Coulombic pair styles discussed here. \( C \) is an energy-conversion constant and epsilon is the dielectric constant which can be set by the dielectric command. The same is true of the equations that follow for other dipole pair styles.

Style \( lj/sf/dipole/sf \) computes “shifted-force” interactions between pairs of particles that each have a charge and/or a point dipole moment. In general, a shifted-force potential is a (slightly) modified potential containing extra terms that make both the energy and its derivative go to zero at the cutoff distance; this removes (cutoff-related) problems in energy conservation and any numerical instability in the equations of motion (Allen). Shifted-force interactions for the Lennard-Jones (\( E_{LJ} \)), charge-charge (\( E_{qq} \)), charge-dipole (\( E_{qp} \)), dipole-charge (\( E_{pq} \)) and dipole-dipole (\( E_{pp} \))
potentials are computed by these formulas for the energy (E), force (F), and torque (T) between particles I and J:

\[ E_{LJ} = 4\epsilon \left\{ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right\} + \left[ 6 \left( \frac{\sigma}{r_c} \right)^{12} - 3 \left( \frac{\sigma}{r_c} \right)^{6} \right] \left( \frac{\sigma}{r_c} \right)^{2} - 7 \left( \frac{\sigma}{r_c} \right)^{12} + 4 \left( \frac{\sigma}{r_c} \right)^{6} \right\} \]

\[ E_{qq} = \frac{q_i q_j}{r} \left( 1 - \frac{r^2}{r_c^2} \right)^2 \]

\[ E_{pq} = E_{p} = -\frac{q_i q_j}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] (\vec{p} \cdot \vec{r}) \]

\[ E_{pp} = \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] \left[ \frac{1}{r^3} (\vec{p}_i \cdot \vec{p}_j) - \frac{3}{r^3} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \cdot \vec{r}) \right] \]

\[ F_{LJ} = \left\{ 48\epsilon \left( \frac{\sigma}{r} \right)^{12} - 24\epsilon \left( \frac{\sigma}{r} \right)^{6} \right\} \frac{1}{r^2} - \left[ 48\epsilon \left( \frac{\sigma}{r_c} \right)^{12} - 24\epsilon \left( \frac{\sigma}{r_c} \right)^{6} \right] \frac{1}{r^2} \right\} \vec{r} \]

\[ F_{qq} = \frac{q_i q_j}{r^3} \left( \frac{1}{r^2} - \frac{1}{r_c^2} \right) \vec{r} \]

\[ F_{pq} = F_{ij} = -\frac{3q_i q_j}{r^3} \left\{ 1 - \left( \frac{r}{r_c} \right)^2 \right\} (\vec{p} \cdot \vec{r}) \vec{r} + \frac{q_i q_j}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] \vec{p} \]

\[ F_{pp} = \frac{3}{r^3} \left\{ \left[ 1 - \left( \frac{r}{r_c} \right)^4 \right] \left[ (\vec{p}_i \cdot \vec{p}_j) - \frac{3}{r^2} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \cdot \vec{r}) \right] \vec{r} + \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] \left[ (\vec{p}_j \cdot \vec{r})\vec{p}_i + (\vec{p}_i \cdot \vec{r})\vec{p}_j - \frac{2}{r^2} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \cdot \vec{r}) \vec{r} \right] \right\} \]

\[ T_{pq} = T_{ij} = \frac{q_i q_j}{r^3} \left\{ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right\} (\vec{p}_i \times \vec{r}) \]

\[ T_{pp} = T_{ij} = -\frac{q_i q_j}{r^3} \left\{ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right\} (\vec{p}_j \times \vec{r}) \]

\[ T_{pp} = T_{ij} = -\frac{q_i q_j}{r^3} \left\{ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right\} (\vec{p}_i \times \vec{r}) + \frac{3}{r^5} \left\{ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right\} (\vec{p}_j \times \vec{r}) \]

where \( \epsilon \) and \( \sigma \) are the standard LJ parameters, \( r_c \) is the cutoff, \( q_i \) and \( q_j \) are the charges on the two particles, \( \vec{p}_i \) and \( \vec{p}_j \) are the dipole moment vectors of the two particles, \( r \) is their separation distance, and the vector \( r = Ri - Rj \) is the
separation vector between the two particles. Note that $E_{qq}$ and $F_{qq}$ are simply Coulombic energy and force, $F_{ij} = -F_{ji}$ as symmetric forces, and $T_{ij} \neq -T_{ji}$ since the torques do not act symmetrically. The shifted-force formula for the Lennard-Jones potential is reported in (Stoddard). The original (non-shifted) formulas for the electrostatic potentials, forces and torques can be found in (Price). The shifted-force electrostatic potentials have been obtained by applying equation 5.13 of (Allen). The formulas for the corresponding forces and torques have been obtained by applying the ‘chain rule’ as in appendix C.3 of (Allen).

If one cutoff is specified in the `pair_style` command, it is used for both the LJ and Coulombic (q,p) terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic (q,p) terms respectively. This pair style also supports an optional `scale` keyword as part of a `pair_coeff` statement, where the interactions can be scaled according to this factor. This scale factor is also made available for use with fix adapt.

Style `lj/cut/dipole/long` computes long-range point-dipole interactions as discussed in (Toukmaji). Dipole-dipole, dipole-charge, and charge-charge interactions are all supported, along with the standard 12/6 Lennard-Jones interactions, which are computed with a cutoff. A `kspace_style` must be defined to use this pair style. Currently, only `kspace_style ewald/disp` support long-range point-dipole interactions.

Style `lj/long/dipole/long` also computes point-dipole interactions as discussed in (Toukmaji). Long-range dipole-dipole, dipole-charge, and charge-charge interactions are all supported, along with the standard 12/6 Lennard-Jones interactions. LJ interactions can be cutoff or long-ranged.

For style `lj/long/dipole/long`, if `flag_lj` is set to `long`, no cutoff is used on the LJ $1/r^6$ dispersion term. The long-range portion is calculated by using the `kspace_style ewald/disp` command. The specified LJ cutoff then determines which portion of the LJ interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the Kspace style. If `flag_lj` is set to `cut`, the LJ interactions are simply cutoff, as with `pair_style lj/cut`. If `flag_lj` is set to `off`, LJ interactions are not computed at all.

If `flag_coul` is set to `long`, no cutoff is used on the Coulombic or dipole interactions. The long-range portion is calculated by using `ewald/disp` of the `kspace_style` command. If `flag_coul` is set to `off`, Coulombic and dipole interactions are not computed at all.

Atoms with dipole moments should be integrated using the `fix nve/sphere update dipole` or the `fix nvt/sphere update dipole` command to rotate the dipole moments. The `omega` option on the `fix langevin` command can be used to thermostat the rotational motion. The `compute temp/sphere` command can be used to monitor the temperature, since it includes rotational degrees of freedom. The `atom_style hybrid dipole sphere` command should be used since it defines the point dipoles and their rotational state. The magnitude and orientation of the dipole moment for each particle can be defined by the `set` command or in the “Atoms” section of the data file read in by the `read_data` command.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the `pair_style` command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I \neq J, the epsilon and sigma coefficients and cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

For atom type pairs I,J and I \neq J, the A, sigma, d1, and d2 coefficients and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. D1 and d2 are distance values and are mixed like sigma. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction; such energy goes to zero at the cutoff by construction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.145.4 Restrictions

The lj/cut/dipole/cut, lj/cut/dipole/long, and lj/long/dipole/long styles are part of the DIPOLE package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The lj/sf/dipole/sf style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Using dipole pair styles with electron units is not currently supported.

pair_coeff 1 1 1.0 1.0
```

18.152.3 Description

Style `dpd` computes a force field for dissipative particle dynamics (DPD) following the exposition in (Groot).

Style `dpd/tstat` invokes a DPD thermostat on pairwise interactions, which is equivalent to the non-conservative portion of the DPD force field. This pair-wise thermostat can be used in conjunction with any `pair style`, and in lieu of per-particle thermostats like `fix langevin` or ensemble thermostats like Nose Hoover as implemented by `fix nvt`. To use `dpd/tstat` as a thermostat for another pair style, use the `pair_style hybrid/overlay` command to compute both the desired pair interaction and the thermostat for each pair of particles.
For style \textit{dpd}, the force on atom I due to atom J is given as a sum of 3 terms

\[
\vec{f} = (F^C + F^D + F^R) \hat{r}_{ij} \quad r < r_c
\]

\[
F^C = Aw(r)
\]

\[
F^D = -\gamma w^2(r)(\vec{r}_{ij} \cdot \vec{v}_{ij})
\]

\[
F^R = \sigma w(r)\alpha(\Delta t)^{-1/2}
\]

\[
w(r) = 1 - r/r_c
\]

where \(F^C\) is a conservative force, \(F^D\) is a dissipative force, and \(F^R\) is a random force. \(\hat{r}_{ij}\) is a unit vector in the direction \(r_i - r_j\), \(v_{ij}\) is the vector difference in velocities of the two atoms. \(\alpha\) is a Gaussian random number with zero mean and unit variance, \(\Delta t\) is the timestep size, and \(w(r)\) is a weighting factor that varies between 0 and 1. \(r_c\) is the cutoff. \(\sigma\) is set equal to \(\sqrt{2k_B T\gamma}\), where \(k_B\) is the Boltzmann constant and \(T\) is the temperature parameter in the \textit{pair_style} command.

For style \textit{dpd/tstat}, the force on atom I due to atom J is the same as the above equation, except that the conservative \(F^C\) term is dropped. Also, during the run, \(T\) is set each timestep to a ramped value from \(T_{\text{start}}\) to \(T_{\text{stop}}\).

For style \textit{dpd}, the pairwise energy associated with style \textit{dpd} is only due to the conservative force term \(F^C\), and is shifted to be zero at the cutoff distance \(R_c\). The pairwise virial is calculated using all 3 terms. For style \textit{dpd/tstat} there is no pairwise energy, but the last two terms of the formula make a contribution to the virial.

For style \textit{dpd}, the following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands:

- \(A\) (force units)
- \(\gamma\) (force/velocity units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used. Note that \(\sigma\) is set equal to \(\sqrt{2k_B T\gamma}\), where \(k_B\) is the Boltzmann constant and \(T\) is the temperature set by the \textit{pair_style} command so it does not need to be specified.

For style \textit{dpd/tstat}, the coefficients defined for each pair of atoms types via the \textit{pair_coeff} command is the same, except that \(A\) is not included.

The GPU-accelerated versions of these styles are implemented based on the work of \textit{(Afshar)} and \textit{(Phillips)}.

**Note:** If you are modeling DPD polymer chains, you may want to use the \textit{pair_style srp} command in conjunction with these pair styles. It is a soft segmental repulsive potential (SRP) that can prevent DPD polymer chains from crossing each other.

**Note:** The virial calculation for pressure when using these pair styles includes all the components of force listed above, including the random force. Since the random force depends on random numbers, everything that changes the order of atoms in the neighbor list (e.g. different number of MPI ranks or a different neighbor list skin distance) will also change the sequence in which the random numbers are applied and thus the individual forces and therefore also the virial/pressure.

**Note:** Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These pair styles do not support the pair_modify shift option for the energy of the pair interaction. Note that as discussed above, the energy due to the conservative Fc term is already shifted to be 0.0 at the cutoff distance Rc.

The pair_modify table option is not relevant for these pair styles.

These pair style do not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

These pair styles writes their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. Note that the user-specified random number seed is stored in the restart file, so when a simulation is restarted, each processor will re-initialize its random number generator the same way it did initially. This means the random forces will be random, but will not be the same as they would have been if the original simulation had continued past the restart time.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

The dpd/tstat style can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

18.152.4 Restrictions

The default frequency for rebuilding neighbor lists is every 10 steps (see the neigh_modify command). This may be too infrequent for style dpd simulations since particles move rapidly and can overlap by large amounts. If this setting yields a non-zero number of “dangerous” reneighborings (printed at the end of a simulation), you should experiment with forcing reneighboring more often and see if system energies/trajectories change.

These pair styles requires you to use the comm_modify vel yes command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the read_restart command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the read_restart command for more details.

```

18.155.3 Description

Styles `dpd/fdt` and `dpd/fdt/energy` compute the force for dissipative particle dynamics (DPD) simulations. The `dpd/fdt` style is used to perform DPD simulations under isothermal and isobaric conditions, while the `dpd/fdt/energy` style is used to perform DPD simulations under isoenergetic and isenthalpic conditions (see (Lisal)). For DPD simulations in general, the force on atom I due to atom J is given as a sum of 3 terms:

```
f = \left( F^C + F^D + F^R \right) r_{ij} r < r_c
F^C = Aw(r)
F^D = -\gamma w^2(r)(r_{ij} \cdot \vec{v}_{ij})
F^R = \sigma w(r) \alpha (\Delta t)^{-1/2}
w(r) = 1 - r/r_c
```

where $F^C$ is a conservative force, $F^D$ is a dissipative force, and $F^R$ is a random force. $r_{ij}$ is a unit vector in the direction $r_i - r_j$, $\vec{v}_{ij}$ is the vector difference in velocities of the two atoms: $\text{math}$ alpha `is a Gaussian random number with zero mean and unit variance, $\Delta t$ is the timestep size, and $w(r)$ is a weighting factor that varies between 0 and 1. $r_c$ is the cutoff. The weighting factor, $\omega_{ij}$, varies between 0 and 1, and is chosen to have the following functional form:

```
\omega_{ij} = 1 - \frac{r_{ij}}{r_c}
```
Note that alternative definitions of the weighting function exist, but would have to be implemented as a separate pair style command.

For style \textit{dpd/fdt}, the fluctuation-dissipation theorem defines $\gamma$ to be set equal to $\sigma^2/(2T)$, where $T$ is the set point temperature specified as a pair style parameter in the above examples. The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands:

- A (force units)
- $\sigma$ (force*time$^{1/2}$ units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used.

Style \textit{dpd/fdt/energy} is used to perform DPD simulations under isoenergetic and isoenthalpic conditions. The fluctuation-dissipation theorem defines $\gamma$ to be set equal to $\sigma^2/(2\Theta)$, where $\Theta$ is the average internal temperature for the pair. The particle internal temperature is related to the particle internal energy through a mesoscale equation of state (see \textit{fix eos}). The differential internal conductive and mechanical energies are computed within style \textit{dpd/fdt/energy} as:

\[
du_{\text{cond}}^i = \kappa_{ij} \left( \frac{1}{\theta_i} - \frac{1}{\theta_j} \right) \omega_{ij}^2 + \alpha_{ij} \omega_{ij}^2 \Theta_{ij} \left( \Delta t \right)^{-1/2}
\]
\[
du_{\text{mech}}^i = -\frac{1}{2} \gamma_{ij} \omega_{ij}^2 \left( \frac{\vec{r}_{ij}}{r_{ij}} \bullet \vec{v}_{ij} \right)^2 - \frac{\sigma_{ij}^2}{4} \left( \frac{1}{m_i} + \frac{1}{m_j} \right) \omega_{ij}^2 - \frac{1}{2} \sigma_{ij} \omega_{ij}^2 \left( \frac{\vec{r}_{ij}}{r_{ij}} \bullet \vec{v}_{ij} \right) \Theta_{ij} \left( \Delta t \right)^{-1/2}
\]

where

\[
\alpha_{ij} = 2k_B \kappa_{ij}
\]
\[
\sigma_{ij}^2 = 2\gamma_{ij} k_B \Theta_{ij}
\]
\[
\Theta_{ij}^{-1} = \frac{1}{2} \left( \frac{1}{\theta_i} + \frac{1}{\theta_j} \right)
\]

$\Theta_{ij}$ is a second Gaussian random number with zero mean and unit variance that is used to compute the internal conductive energy. The fluctuation-dissipation theorem defines $\alpha$ to be set equal to $2k_B \kappa$, where $\kappa$ is the mesoscale thermal conductivity parameter. The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands:

- A (force units)
- $\sigma$ (force*time$^{1/2}$ units)
- $\kappa$ (energy*temperature/time units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used.

The pairwise energy associated with styles \textit{dpd/fdt} and \textit{dpd/fdt/energy} is only due to the conservative force term $F_c$, and is shifted to be zero at the cutoff distance $R_c$. The pairwise virial is calculated using only the conservative term.

The forces computed through the \textit{dpd/fdt} and \textit{dpd/fdt/energy} styles can be integrated with the velocity-Verlet integration scheme or the Shardlow splitting integration scheme described by (Lisal). In the cases when these pair styles are combined with the \textit{fix shardlow}, these pair styles differ from the other dpd styles in that the dissipative and random forces are split from the force calculation and are not computed within the pair style. Thus, only the conservative force is computed by the pair style, while the stochastic integration of the dissipative and random forces are handled through the Shardlow splitting algorithm approach. The Shardlow splitting algorithm is advantageous, especially when performing DPD under isoenergetic conditions, as it allows significantly larger timesteps to be taken.
LAMMPS Documentation

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix command-line switch} when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

\section{18.155.4 Restrictions}

These commands are part of the USER-DPD package. They are only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

Pair styles \texttt{dpdfdr} and \texttt{dpdfdt/energy} require use of the \texttt{comm_modify vel yes} option so that velocities are stored by ghost atoms.

Pair style \texttt{dpdfdt/energy} requires \texttt{atom_style dpd} to be used in order to properly account for the particle internal energies and temperatures.

\section{18.155.5 Related commands}

\texttt{pair_coeff, fix shardlow}

\textbf{Default:} none

\cite{lisal2011dissipative}

\section{18.156 pair_style drip command}

\subsection{18.156.1 Syntax}

\begin{verbatim}
pair_style hybrid/overlay drip [styles ...]

- styles = other styles to be overlayed with drip (optional)
\end{verbatim}

\cite{lisal2011dissipative}
18.156.2 Examples

```plaintext
pair_style hybrid/overlay drip
pair_coeff * * none
pair_coeff * * drip C.drip C

pair_style hybrid/overlay drip rebo
pair_coeff * * drip C.drip C
pair_coeff * * rebo CH.airebo C

pair_style hybrid/overlay drip rebo
pair_coeff * * drip C.drip C NULL
pair_coeff * * rebo CH.airebo C H
```

18.156.3 Description

Style `drip` computes the interlayer interactions of layered materials using the dihedral-angle-corrected registry-dependent (DRIP) potential as described in (Wen), which is based on the (Kolmogorov) potential and provides an improved prediction for forces. The total potential energy of a system is

\[
E = \frac{1}{2} \sum_i \sum_{j \neq \text{layer } i} \phi_{ij}
\]

\[
\phi_{ij} = f_c(x_r) \left[ e^{-\lambda(r_{ij} - z_0)} \left( C + g(\rho_{ij}, \{\alpha_{ij}^{(m)}\}) \right) - A \left( \frac{z_0}{r_{ij}} \right)^6 \right]
\]

where the \( r^{-6} \) term models the attractive London dispersion, the exponential term is designed to capture the registry effect due to overlapping \( pi \) bonds, and \( f_c \) is a cutoff function.

This potential (DRIP) only provides the interlayer interactions between graphene layers. So, to perform a realistic simulation, it should be used in combination with an intralayer potential such as `REBO` and `Tersoff`. To keep the intralayer interactions unaffected, we should avoid applying DRIP to contribute energy to intralayer interactions. This can be achieved by assigning different molecular IDs to atoms in different layers, and DRIP is implemented such that only atoms with different molecular ID can interact with each other. For this purpose, `atom style` “molecular” or “full” has to be used.

On the other way around, `REBO` (`Tersoff` or any other potential used to provide the intralayer interactions) should not interfere with the interlayer interactions described by DRIP. This is typically automatically achieved using the commands provided in the `Examples` section above, since the cutoff distance for carbon-carbon interaction in the intralayer potentials (e.g. 2 Angstrom for `REBO`) is much smaller than the equilibrium layer distance of graphene layers (about 3.4 Angstrom). If you want, you can enforce this by assigning different atom types to atoms in different layers, and apply an intralayer potential to one atom type. See `pair_hybrid` for details.

The `pair_coeff` command for DRIP takes \( 4+N \) arguments, where \( N \) is the number of LAMMPS atom types. The first three arguments must be fixed to be \(* * drip\), the fourth argument is the path to the DRIP parameter file, and the remaining \( N \) arguments specifying the mapping between element in the parameter file and atom types. For example, if your LAMMPS simulation has 3 atom types and you want all of them to be C, you would use the following `pair_coeff` command:

```plaintext
pair_coeff * * drip C.drip C C C
```

If a mapping value is specified as NULL, the mapping is not performed. This could be useful when DRIP is used to model part of the system where other element exists. Suppose you have a hydrocarbon system, with C of atom type 1 and H of atom type 2, you can use the following command to inform DRIP not to model H atoms:
The potential parameters developed in (Wen) are provided with LAMMPS (see the “potentials” directory). Besides those in Wen, an additional parameter “normal_cutoff”, specific to the LAMMPS implementation, is used to find the three nearest neighbors of an atom to construct the normal.

Mixing, shift, table, tail correction, and restart info:
This pair style does not support the pair_modify mix, shift, table, and tail options.
This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

18.156.4 Restrictions
This pair style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair potential requires the newton setting to be “on” for pair interactions.
The C.drip parameter file provided with LAMMPS (see the “potentials” directory) is parameterized for metal units. You can use the DRIP potential with any LAMMPS units, but you would need to create your own custom parameter file with coefficients listed in the appropriate units, if your simulation does not use “metal” units.

18.157 pair_style dsmc command

18.157.1 Syntax

pair_style dsmc max_cell_size seed weighting Tref Nrecompute Nsample

- max_cell_size = global maximum cell size for DSMC interactions (distance units)
- seed = random # seed (positive integer)
- weighting = macroparticle weighting
- Tref = reference temperature (temperature units)
- Nrecompute = re-compute v*sigma_max every this many timesteps (timesteps)
- Nsample = sample this many times in recomputing v*sigma_max
18.157.2 Examples

```plaintext
pair_style dsmc 2.5 34387 10 1.0 100 20
pair_coeff * * 1.0
pair_coeff 1 1 1.0
```

18.157.3 Description

Style *dsmc* computes collisions between pairs of particles for a direct simulation Monte Carlo (DSMC) model following the exposition in *(Bird)*. Each collision resets the velocities of the two particles involved. The number of pairwise collisions for each pair or particle types and the length scale within which they occur are determined by the parameters of the *pair_style* and *pair_coeff* commands.

Stochastic collisions are performed using the variable hard sphere (VHS) approach, with the user-defined *max_cell_size* value used as the maximum DSMC cell size, and reference cross-sections for collisions given using the *pair_coeff* command.

There is no pairwise energy or virial contributions associated with this pair style.

The following coefficient must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- sigma (area units, i.e. distance-squared)

The global DSMC *max_cell_size* determines the maximum cell length used in the DSMC calculation. A structured mesh is overlaid on the simulation box such that an integer number of cells are created in each direction for each processor’s sub-domain. Cell lengths are adjusted up to the user-specified maximum cell size.

To perform a DSMC simulation with LAMMPS, several additional options should be set in your input script, though LAMMPS does not check for these settings.

Since this pair style does not compute particle forces, you should use the “fix nve/noforce” time integration fix for the DSMC particles, e.g.

```plaintext
fix 1 all nve/noforce
```

This pair style assumes that all particles will communicated to neighboring processors every timestep as they move. This makes it possible to perform all collisions between pairs of particles that are on the same processor. To ensure this occurs, you should use these commands:

```plaintext
neighbor 0.0 bin
neigh_modify every 1 delay 0 check no
atom_modify sort 0 0.0
communicate single cutoff 0.0
```

These commands ensure that LAMMPS communicates particles to neighboring processors every timestep and that no ghost atoms are created. The output statistics for a simulation run should indicate there are no ghost particles or neighbors.

In order to get correct DSMC collision statistics, users should specify a Gaussian velocity distribution when populating the simulation domain. Note that the default velocity distribution is uniform, which will not give good DSMC collision rates. Specify “dist gaussian” when using the *velocity* command as in the following:

```plaintext
velocity all create 594.6 87287 loop geom dist gaussian
```
Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This pair style does not support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. Note that the user-specified random number seed is stored in the restart file, so when a simulation is restarted, each processor will re-initialize its random number generator the same way it did initially. This means the random forces will be random, but will not be the same as they would have been if the original simulation had continued past the restart time.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

---

18.157.4 Restrictions

This style is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

pair_coeff  *  * e3b preset 2011
```

18.158.3 Description

The e3b style computes an "explicit three-body" (E3B) potential for water (Kumar 2008).

\[
E = E_2 \sum_{i,j} e^{-k_2 r_{ij}} + E_A \sum_{i,j,k,\ell} f(r_{ij}) f(r_{kl}) + E_B \sum_{i,j,k,\ell} f(r_{ij}) f(r_{kl}) + E_C \sum_{i,j,k,\ell} f(r_{ij}) f(r_{kl})
\]

\[
f(r) = e^{-k_3 s(r)}
\]

\[
s(r) = \begin{cases} 
1 & r < R_s \\
\frac{(R_f - r)^2(R_f - 3R_s + 2r)}{(R_f - R_s)^3} & R_s \leq r \leq R_f \\
0 & r > R_f 
\end{cases}
\]

This potential was developed as a water model that includes the three-body cooperativity of hydrogen bonding explicitly. To use it in this way, it must be applied in conjunction with a conventional two-body water model, through pair_style hybrid/overlay. The three body interactions are split into three types: A, B, and C. Type A corresponds to anti-cooperative double hydrogen bond donor interactions. Type B corresponds to the cooperative interaction of molecules that both donate and accept a hydrogen bond. Type C corresponds to anti-cooperative double hydrogen bond acceptor interactions. The three-body interactions are smoothly cutoff by the switching function s(r) between Rs and Rc3. The two-body interactions are designed to correct for the effective many-body interactions implicitly included in the conventional two-body potential. The two-body interactions are cut off sharply at Rc2, because K3 is typically significantly smaller than K2. See (Kumar 2008) for more details.
Only a single `pair_coeff` command is used with the `e3b` style. The first two arguments must be `* *`. The oxygen atom type for the pair style is passed as the only argument to the `pair_style` command, not in the `pair_coeff` command. The hydrogen atom type is inferred by the ordering of the atoms.

**Note:** Every atom of type Otype must be part of a water molecule. Each water molecule must have consecutive IDs with the oxygen first. This pair style does not test that this criteria is met.

The `pair_coeff` command must have at least one keyword/value pair, as described above. The `preset` keyword sets the potential parameters to the values used in *(Tainter 2011)* or *(Tainter 2015)*. To use the water models defined in those references, the `e3b` style should always be used in conjunction with an `lj/cut/tip4p/long` style through `pair_style hybrid/overlay`, as demonstrated in the second example above. The `preset 2011` option should be used with the *TIP4P water model*. The `preset 2015` option should be used with the *TIP4P/2005 water model*. If the `preset` keyword is used, no other keyword is needed. Changes to the preset parameters can be made by specifying the `preset` keyword followed by the specific parameter to change, like `Ea`. Note that the other keywords must come after `preset` in the `pair_style` command. The `e3b` style can also be used to implement any three-body potential of the same form by specifying all the keywords except `neigh`: `Ea`, `Eb`, `Ec`, `E2`, `K3`, `K2`, `Rc3`, `Rc2`, `Rs`, and `bondL`. The keyword `bondL` specifies the intramolecular OH bond length of the water model being used. This is needed to include H atoms that are within the cutoff even when the attached oxygen atom is not.

This pair style allocates arrays sized according to the number of pairwise interactions within `Rc3`. To do this it needs an estimate for the number of water molecules within `Rc3` of an oxygen atom. This estimate defaults to 10 and can be changed using the `neigh` keyword, which takes an integer as an argument. If the `neigh` setting is too small, the simulation will fail with the error “neigh is too small”. If the `neigh` setting is too large, the pair style will use more memory than necessary.

This pair style tallies a breakdown of the total E3B potential energy into sub-categories, which can be accessed via the `compute pair` command as a vector of values of length 4. The 4 values correspond to the terms in the first equation above: the `E2` term, the `Ea` term, the `Eb` term, and the `Ec` term.

See the examples/USER/misc/e3b directory for a complete example script.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style is incompatible with `respa`.

### 18.158.4 Restrictions

This pair style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

This pair style requires a fixed number of atoms in the simulation, so it is incompatible with fixes like `fix deposit`. If the number of atoms changes between runs, this pair style must be re-initialized by calling the `pair_style` and `pair_coeff` commands. This is not a fundamental limitation of the pair style, but the code currently does not support a variable number of atoms.

The `preset` keyword currently only works with real, metal, si, and cgs units.

```

18.178.3 Description

Style *eam* computes pairwise interactions for metals and metal alloys using embedded-atom method (EAM) potentials *(Daw)*. The total energy $E_i$ of an atom $I$ is given by

$$ E_i = F_{\alpha} \left( \sum_{j \neq i} \rho_{\beta}(r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha \beta}(r_{ij}) $$

where $F$ is the embedding energy which is a function of the atomic electron density $\rho$, $\phi$ is a pair potential interaction, and $\alpha$ and $\beta$ are the element types of atoms $I$ and $J$. The multi-body nature of the EAM potential is a result of the embedding energy term. Both summations in the formula are over all neighbors $J$ of atom $I$ within the cutoff distance.

The cutoff distance and the tabulated values of the functionals $F$, $\rho$, and $\phi$ are listed in one or more files which are specified by the pair_coeff command. These are ASCII text files in a DYNAMO-style format which is described below. DYNAMO was the original serial EAM MD code, written by the EAM originators. Several DYNAMO potential files for different metals are included in the “potentials” directory of the LAMMPS distribution. All of these files are parameterized in terms of LAMMPS metal units.

**Note:** The *eam* style reads single-element EAM potentials in the DYNAMO funcfl format. Either single element or alloy systems can be modeled using multiple funcfl files and style *eam*. For the alloy case LAMMPS mixes the single-element potentials to produce alloy potentials, the same way that DYNAMO does. Alternatively, a single DYNAMO setfl file or Finnis/Sinclair EAM file can be used by LAMMPS to model alloy systems by invoking the *eam/alloy* or *eam/cd* or *eam/fs* styles as described below. These files require no mixing since they specify alloy interactions explicitly.

**Note:** Note that unlike for other potentials, cutoffs for EAM potentials are not set in the pair_style or pair_coeff command; they are specified in the EAM potential files themselves. Likewise, the EAM potential files list atomic masses; thus you do not need to use the mass command to specify them.

There are several WWW sites that distribute and document EAM potentials stored in DYNAMO or other formats:
These potentials should be usable with LAMMPS, though the alternate formats would need to be converted to the DYNAMO format used by LAMMPS and described on this page. The NIST site is maintained by Chandler Becker (cbecker at nist.gov) who is good resource for info on interatomic potentials and file formats.

The OpenKIM Project at https://openkim.org/browse/models/by-type provides EAM potentials that can be used directly in LAMMPS with the kim_commands interface.

For style *eam*, potential values are read from a file that is in the DYNAMO single-element *funcfl* format. If the DYNAMO file was created by a Fortran program, it cannot have “D” values in it for exponents. C only recognizes “e” or “E” for scientific notation.

Note that unlike for other potentials, cutoffs for EAM potentials are not set in the pair_style or pair_coeff command; they are specified in the EAM potential files themselves.

For style *eam* a potential file must be assigned to each I,I pair of atom types by using one or more pair_coeff commands, each with a single argument:

- filename

Thus the following command

```
pair_coeff +2 1+2 cuu3.eam
```

will read the cuu3 potential file and use the tabulated Cu values for F, phi, rho that it contains for type pairs 1,1 and 2,2 (type pairs 1,2 and 2,1 are ignored). See the pair_coeff doc page for alternate ways to specify the path for the potential file. In effect, this makes atom types 1 and 2 in LAMMPS be Cu atoms. Different single-element files can be assigned to different atom types to model an alloy system. The mixing to create alloy potentials for type pairs with I != J is done automatically the same way that the serial DYNAMO code originally did it; you do not need to specify coefficients for these type pairs.

*Funcfl* files in the potentials directory of the LAMMPS distribution have an “.eam” suffix. A DYNAMO single-element *funcfl* file is formatted as follows:

- line 1: comment (ignored)
- line 2: atomic number, mass, lattice constant, lattice type (e.g. FCC)
- line 3: Nrho, drho, Nr, dr, cutoff

On line 2, all values but the mass are ignored by LAMMPS. The mass is in mass units, e.g. mass number or grams/mole for metal units. The cubic lattice constant is in Angstroms. On line 3, Nrho and Nr are the number of tabulated values in the subsequent arrays, drho and dr are the spacing in density and distance space for the values in those arrays, and the specified cutoff becomes the pairwise cutoff used by LAMMPS for the potential. The units of dr are Angstroms; I’m not sure of the units for drho - some measure of electron density.

Following the three header lines are three arrays of tabulated values:

- embedding function F(rho) (Nrho values)
- effective charge function Z(r) (Nr values)
- density function rho(r) (Nr values)

The values for each array can be listed as multiple values per line, so long as each array starts on a new line. For example, the individual Z(r) values are for r = 0,dr,2*dr,... (Nr-1)*dr.
The units for the embedding function $F$ are eV. The units for the density function $\rho$ are the same as for $\text{drho}$ (see above, electron density). The units for the effective charge $Z$ are “atomic charge” or $\text{sqrt}\text{(Hartree} \times \text{Bohr-radii)}$. For two interacting atoms $i,j$ this is used by LAMMPS to compute the pair potential term in the EAM energy expression as $r^2\phi$, in units of eV-Angstroms, via the formula

$$r \cdot \phi = 27.2 \cdot 0.529 \cdot Z_i \cdot Z_j$$

where 1 Hartree = 27.2 eV and 1 Bohr = 0.529 Angstroms.

Style eam/alloy computes pairwise interactions using the same formula as style eam. However the associated pair_coeff command reads a DYNAMO setfl file instead of a funcfl file. Setfl files can be used to model a single-element or alloy system. In the alloy case, as explained above, setfl files contain explicit tabulated values for alloy interactions. Thus they allow more generality than funcfl files for modeling alloys.

For style eam/alloy, potential values are read from a file that is in the DYNAMO multi-element setfl format, except that element names (Ni, Cu, etc) are added to one of the lines in the file. If the DYNAMO file was created by a Fortran program, it cannot have “D” values in it for exponents. C only recognizes “e” or “E” for scientific notation.

Only a single pair_coeff command is used with the eam/alloy style which specifies a DYNAMO setfl file, which contains information for $M$ elements. These are mapped to LAMMPS atom types by specifying $N$ additional arguments after the filename in the pair_coeff command, where $N$ is the number of LAMMPS atom types:

- filename
- $N$ element names = mapping of setfl elements to atom types

As an example, the potentials/NiAlH_jea.eam.alloy file is a setfl file which has tabulated EAM values for 3 elements and their alloy interactions: Ni, Al, and H. See the pair_coeff doc page for alternate ways to specify the path for the potential file. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Ni, and the fourth to be Al, you would use the following pair_coeff command:

```
pair_coeff * * NiAlH_jea.eam.alloy Ni Ni Ni Al
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Ni arguments map LAMMPS atom types 1,2,3 to the Ni element in the setfl file. The final Al argument maps LAMMPS atom type 4 to the Al element in the setfl file. Note that there is no requirement that your simulation use all the elements specified by the setfl file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an eam/alloy potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Setfl files in the potentials directory of the LAMMPS distribution have an “.eam.alloy” suffix. A DYNAMO multi-element setfl file is formatted as follows:

- lines 1,2,3 = comments (ignored)
- line 4: Nelements Element1 Element2 ... ElementN
- line 5: Nrho, drho, Nr, dr, cutoff

In a DYNAMO setfl file, line 4 only lists Nelements = the # of elements in the setfl file. For LAMMPS, the element name (Ni, Cu, etc) of each element must be added to the line, in the order the elements appear in the file.

The meaning and units of the values in line 5 is the same as for the funcfl file described above. Note that the cutoff (in Angstroms) is a global value, valid for all pairwise interactions for all element pairings.

Following the 5 header lines are Nelements sections, one for each element, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
• embedding function \( F(\rho) \) (\( NRho \) values)
• density function \( \rho(r) \) (\( Nr \) values)

As with the *funcfl* files, only the mass (in mass units, e.g. mass number or grams/mole for metal units) is used by LAMMPS from the first line. The cubic lattice constant is in Angstroms. The \( F \) and \( \rho \) arrays are unique to a single element and have the same format and units as in a *funcfl* file.

Following the Nelements sections, \( Nr \) values for each pair potential \( \phi(r) \) array are listed for all \( i,j \) element pairs in the same format as other arrays. Since these interactions are symmetric (\( i,j = j,i \)) only \( \phi \) arrays with \( i \geq j \) are listed, in the following order: \( i,j = (1,1), (2,1), (2,2), (3,1), (3,2), (3,3), (4,1), \ldots \) (Nelements, Nelements). Unlike the effective charge array \( Z(r) \) in *funcfl* files, the tabulated values for each \( \phi \) function are listed in *setfl* files directly as \( r^2 \phi \) (in units of eV-Angstroms), since they are for atom pairs.

Style *eam/cd* is similar to the *eam/alloy* style, except that it computes alloy pairwise interactions using the concentration-dependent embedded-atom method (CD-EAM). This model can reproduce the enthalpy of mixing of alloys over the full composition range, as described in *(Stukowski).* Style *eam/cd/old* is an older, slightly different and slower two-site formulation of the model *(Caro).*

The pair_coeff command is specified the same as for the *eam/alloy* style. However the DYNAMO *setfl* file must have two lines added to it, at the end of the file:

- line 1: Comment line (ignored)
- line 2: \( N \) Coefficient0 Coefficient1 \ldots Coefficient\( N \)

The last line begins with the degree \( N \) of the polynomial function \( h(x) \) that modifies the cross interaction between A and B elements. Then \( N+1 \) coefficients for the terms of the polynomial are then listed.

Modified EAM *setfl* files used with the *eam/cd* style must contain exactly two elements, i.e. in the current implementation the *eam/cd* style only supports binary alloys. The first and second elements in the input EAM file are always taken as the \( A \) and \( B \) species.

CD-EAM files in the *potentials* directory of the LAMMPS distribution have a “.cdeam” suffix.

Style *eam/fs* computes pairwise interactions for metals and metal alloys using a generalized form of EAM potentials due to Finnis and Sinclair *(Finnis).* The total energy \( E_i \) of an atom \( I \) is given by

\[
E_i = F_\alpha \left( \sum_{j \neq i} \rho_{\alpha\beta}(r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha\beta}(r_{ij})
\]

This has the same form as the EAM formula above, except that rho is now a functional specific to the atomic types of both atoms \( I \) and \( J \), so that different elements can contribute differently to the total electron density at an atomic site depending on the identity of the element at that atomic site.

The associated pair_coeff command for style *eam/fs* reads a DYNAMO *setfl* file that has been extended to include additional rho_alpha_beta arrays of tabulated values. A discussion of how FS EAM differs from conventional EAM alloy potentials is given in *(Ackland1).* An example of such a potential is the same author’s Fe-P FS potential *(Ackland2).* Note that while FS potentials always specify the embedding energy with a square root dependence on the total density, the implementation in LAMMPS does not require that; the user can tabulate any functional form desired in the FS potential files.

For style *eam/fs*, the form of the pair_coeff command is exactly the same as for style *eam/alloy*, e.g.

```
pair_coeff * * NiAlH_jea.eam.fs Ni Ni Ni Al
```
where there are N additional arguments after the filename, where N is the number of LAMMPS atom types. See the `pair_coeff` doc page for alternate ways to specify the path for the potential file. The N values determine the mapping of LAMMPS atom types to EAM elements in the file, as described above for style `eam/alloy`. As with `eam/alloy`, if a mapping value is NULL, the mapping is not performed. This can be used when an `eam/fs` potential is used as part of the hybrid pair style. The NULL values are used as placeholders for atom types that will be used with other potentials.

FS EAM files include more information than the DYNAMO `setfl` format files read by `eam/alloy`, in that i,j density functionals for all pairs of elements are included as needed by the Finnis/Sinclair formulation of the EAM.

FS EAM files in the `potentials` directory of the LAMMPS distribution have an “.eam.fs” suffix. They are formatted as follows:

- lines 1,2,3 = comments (ignored)
- line 4: Nelements Element1 Element2 ... ElementN
- line 5: Nrho, drho, Nr, dr, cutoff

The 5-line header section is identical to an EAM `setfl` file.

Following the header are Nelements sections, one for each element I, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function F(rho) (Nrho values)
- density function rho(r) for element I at element 1 (Nr values)
- density function rho(r) for element I at element 2
  ...
- density function rho(r) for element I at element Nelement

The units of these quantities in line 1 are the same as for `setfl` files. Note that the rho(r) arrays in Finnis/Sinclair can be asymmetric (i,j != j,i) so there are Nelements^2 of them listed in the file.

Following the Nelements sections, Nr values for each pair potential phi(r) array are listed in the same manner (r*phi, units of eV-Angstroms) as in EAM `setfl` files. Note that in Finnis/Sinclair, the phi(r) arrays are still symmetric, so only phi arrays for i >= j are listed.

---

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

---

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above with the individual styles. You never need to specify a `pair_coeff` command with I != J arguments for the eam styles.

This pair style does not support the `pair_modify` shift, table, and tail options.
The eam pair styles do not write their information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

The eam pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

18.178.4 Restrictions

All of these styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.181 pair_style edip-multi command

18.181.1 Syntax

pair_style style

- style = edip or edip/multi
18.181.2 Examples

```plaintext
pair_style edip
pair_coeff * * Si.edip Si
```

18.181.3 Description

The `edip` and `edip/multi` styles compute a 3-body \textit{EDIP} potential which is popular for modeling silicon materials where it can have advantages over other models such as the \textit{Stillinger-Weber} or \textit{Tersoff} potentials. The `edip` style has been programmed for single element potentials, while `edip/multi` supports multi-element EDIP runs.

In EDIP, the energy \( E \) of a system of atoms is

\[
E = \sum_{j \neq i} \phi_2(R_{ij}, Z_i) + \sum_{j \neq i} \sum_{k \neq i, k > j} \phi_3(R_{ij}, R_{ik}, Z_i)
\]

\[
\phi_2(r, Z) = A \left[ \left( \frac{B}{r} \right)^\rho - e^{-\beta Z^2} \right] \exp \left( \frac{\sigma}{r - a} \right)
\]

\[
\phi_3(R_{ij}, R_{ik}, Z_i) = \exp \left( \frac{\gamma}{R_{ij} - a} \right) \exp \left( \frac{\gamma}{R_{ik} - a} \right) h(\cos \theta_{ijk}, Z_i)
\]

\[
Z_i = \sum_{m \neq i} f(R_{im}) \quad f(r) = \begin{cases} 1 & r < c \\ \exp \left( \frac{\alpha}{1 - \frac{r}{a}} \right) & c < r < a \\ 0 & r > a \end{cases}
\]

\[
h(l, Z) = \lambda \left[ (1 - e^{-Q(Z)(l + \tau(Z))^2}) + \eta Q(Z)(l + \tau(Z))^2 \right]
\]

\[
Q(Z) = Q_0 e^{-\mu Z} \quad \tau(Z) = u_1 + u_2(e^{u_3 - u_4 Z} - e^{-2u_4 Z})
\]

where \( \phi_2 \) is a two-body term and \( \phi_3 \) is a three-body term. The summations in the formula are over all neighbors \( J \) and \( K \) of atom \( I \) within a cutoff distance = \( a \). Both terms depend on the local environment of atom \( I \) through its effective coordination number defined by \( Z \), which is unity for a cutoff distance < \( c \) and gently goes to 0 at distance = \( a \).

Only a single `pair_coeff` command is used with the `edip` style which specifies an EDIP potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the `pair_coeff` command, where \( N \) is the number of LAMMPS atom types:

- `filename`
- `N element names = mapping of EDIP elements to atom types`

See the `pair_coeff` doc page for alternate ways to specify the path for the potential file.

As an example, imagine a file `Si.edip` has EDIP values for `Si`. EDIP files in the `potentials` directory of the LAMMPS distribution have a “.edip” suffix. Lines that are not blank or comments (starting with `#`) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- A (energy units)
- B (distance units)
- cutoffA (distance units)
• cutoffC (distance units)
• $\alpha$
• $\beta$
• $\eta$
• $\gamma$ (distance units)
• $\lambda$ (energy units)
• $\mu$
• $\tau$
• $\sigma$ (distance units)
• Q0
• u1
• u2
• u3
• u4

The A, B, beta, sigma parameters are used only for two-body interactions. The eta, gamma, lambda, mu, Q0 and all u1 to u4 parameters are used only for three-body interactions. The alpha and cutoffC parameters are used for the coordination environment function only.

The EDIP potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify EDIP parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

At the moment, only a single element parameterization is implemented. However, the author is not aware of other multi-element EDIP parameterization. If you know any and you are interest in that, please contact the author of the EDIP package.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.
This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.181.4 Restrictions

This pair style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The EDIP potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the EDIP potential with any LAMMPS units, but you would need to create your own EDIP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

18.182.3 Description

This pair style contains a LAMMPS implementation of the electron Force Field (eFF) potential currently under development at Caltech, as described in (Jaramillo-Botero). The eFF for Z<6 was first introduced by (Su) in 2007. It has been extended to higher Zs by using effective core potentials (ECPs) that now cover up to second and third row p-block elements of the periodic table.

eFF can be viewed as an approximation to QM wave packet dynamics and Fermionic molecular dynamics, combining the ability of electronic structure methods to describe atomic structure, bonding, and chemistry in materials, and of plasma methods to describe nonequilibrium dynamics of large systems with a large number of highly excited electrons. Yet, eFF relies on a simplification of the electronic wave function in which electrons are described as floating Gaussian wave packets whose position and size respond to the various dynamic forces between interacting classical nuclear particles and spherical Gaussian electron wave packets. The wave function is taken to be a Hartree product of the wave packets. To compensate for the lack of explicit antisymmetry in the resulting wave function, a spin-dependent Pauli potential is included in the Hamiltonian. Substituting this wave function into the time-dependent Schrodinger equation produces equations of motion that correspond - to second order - to classical Hamiltonian relations between electron position and size, and their conjugate momenta. The N-electron wave function is described as a product of one-electron Gaussian functions, whose size is a dynamical variable and whose position is not constrained to a nuclear center. This form allows for straightforward propagation of the wave function, with time, using a simple formulation from which the equations of motion are then integrated with conventional MD algorithms. In addition to this spin-dependent Pauli repulsion term between Gaussians, eFF includes the electron kinetic energy from the Gaussians. These two terms are based on first-principles quantum mechanics. On the other hand, nuclei are described as point charges, which interact with other nuclei and electrons through standard electrostatic potential forms.

The full Hamiltonian (shown below), contains then a standard description for electrostatic interactions between a set of delocalized point and Gaussian charges which include, nuclei-nuclei (NN), electron-electron (ee), and nuclei-electron (Ne). Thus, eFF is a mixed QM-classical mechanics method rather than a conventional force field method (in which electron motions are averaged out into ground state nuclear motions, i.e a single electronic state, and particle interactions are described via empirically parameterized interatomic potential functions). This makes eFF uniquely suited to simulate materials over a wide range of temperatures and pressures where electronically excited and ionized states of matter can occur and coexist. Furthermore, the interactions between particles -nuclei and electrons- reduce to the sum of a set of effective pairwise potentials in the eFF formulation. The eff/cut style computes the pairwise Coulomb interactions between nuclei and electrons (E_{NN,E_{Ne,E_{ee}}}), and the quantum-derived Pauli (E_{PR}) and Kinetic energy interactions potentials between electrons (E_{KE}) for a total energy expression given as,

\[ U(R,r,s) = E_{NN}(R) + E_{Ne}(R,r,s) + E_{ee}(r,s) + E_{KE}(r,s) + E_{PR}(\uparrow\downarrow,S) \]

The individual terms are defined as follows:

\[ E_{KE} = \frac{\hbar^2}{m_e} \sum_s 3 \frac{s^2_i}{2} \]
\[ E_{NN} = \frac{1}{4\pi\varepsilon_0} \sum_{i<j} \frac{Z_i Z_j}{R_{ij}} \]
\[ E_{Ne} = -\frac{1}{4\pi\varepsilon_0} \sum_{i,j} \frac{Z_i}{R_{ij}} \text{Erf} \left( \frac{\sqrt{2} r_{ij}}{s_j} \right) \]
\[ E_{ee} = \frac{1}{4\pi\varepsilon_0} \sum_{i<j} \frac{1}{r_{ij}} \text{Erf} \left( \frac{\sqrt{2} r_{ij}}{\sqrt{s_i^2 + s_j^2}} \right) \]
\[ E_{Pauli} = \sum_{\sigma_i = \sigma_j} E(\uparrow\uparrow)_{ij} + \sum_{\sigma_i \neq \sigma_j} E(\uparrow\downarrow)_{ij} \]

where, s_i correspond to the electron sizes, the sigmas i’s to the fixed spins of the electrons, Z_i to the charges on the...
The overall electrostatics energy is given in Hartree units of energy by default and can be modified by an energy-conversion constant, according to the units chosen (see electron_units). The cutoff Rc, given in Bohrs (by default), truncates the interaction distance. The recommended cutoff for this pair style should follow the minimum image criterion, i.e. half of the minimum unit cell length.

Style eff/long (not yet available) computes the same interactions as style eff/cut except that an additional damping factor is applied so it can be used in conjunction with the kspace_style command and its ewald or pppm option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

This potential is designed to be used with atom_style electron definitions, in order to handle the description of systems with interacting nuclei and explicit electrons.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- cutoff (distance units)

For eff/cut, the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the pair_style command is used.

For eff/long (not yet available) no cutoff will be specified for an individual I,J type pair via the pair_coeff command. All type pairs use the same global cutoff specified in the pair_style command.

The limit/eradius and pressure/evirials keywords are optional. Neither or both must be specified. If not specified they are unset.

The limit/eradius keyword is used to restrain electron size from becoming excessively diffuse at very high temperatures were the Gaussian wave packet representation breaks down, and from expanding as free particles to infinite size. If unset, electron radius is free to increase without bounds. If set, a restraining harmonic potential of the form \( E = \frac{1}{2}k_{ss}s^2 \) for \( s > L_{box}/2 \), where \( k_s = 1 \) Hartrees/Bohr^2, is applied on the electron radius.

The pressure/evirials keyword is used to control between two types of pressure computation: if unset, the computed pressure does not include the electronic radial virials contributions to the total pressure (scalar or tensor). If set, the computed pressure will include the electronic radial virial contributions to the total pressure (scalar and tensor).

The ecp keyword is used to associate an ECP representation for a particular atom type. The ECP captures the orbital overlap between a core pseudo particle and valence electrons within the Pauli repulsion. A list of type:element-symbol pairs may be provided for all ECP representations, after the “ecp” keyword.

Note: Default ECP parameters are provided for C, N, O, Al, and Si. Users can modify these using the pair_coeff command as exemplified above. For this, the User must distinguish between two different functional forms supported, one that captures the orbital overlap assuming the s-type core interacts with an s-like valence electron (s-s) and another that assumes the interaction is s-p. For systems that exhibit significant p-character (e.g. C, N, O) the s-p form is recommended. The “s” ECP form requires 3 parameters and the “p” 5 parameters.

Note: there are two different pressures that can be reported for eFF when defining this pair_style, one (default) that considers electrons do not contribute radial virial components (i.e. electrons treated as incompressible ‘rigid’ spheres) and one that does. The radial electronic contributions to the virials are only tallied if the flexible pressure option is set, and this will affect both global and per-atom quantities. In principle, the true pressure of a system is somewhere in between the rigid and the flexible eFF pressures, but, for most cases, the difference between these two pressures.
LAMMPS Documentation

will not be significant over long-term averaged runs (i.e. even though the energy partitioning changes, the total energy remains similar).

Note: This implementation of eFF gives a reasonably accurate description for systems containing nuclei from Z = 1-6 in “all electron” representations. For systems with increasingly non-spherical electrons, Users should use the ECP representations. ECPs are now supported and validated for most of the second and third row elements of the p-block. Predefined parameters are provided for C, N, O, Al, and Si. The ECP captures the orbital overlap between the core and valence electrons (i.e. Pauli repulsion) with one of the functional forms:

$$E_{Pauli(EC_{P_{s}})} = p_{1} \exp \left( - \frac{p_{2}r^{2}}{p_{3} + s^{2}} \right)$$

$$E_{Pauli(EC_{P_{p}})} = p_{1} \left( \frac{2}{p_{2}/s + s/p_{2}} \right) (r - p_{3}s)^{2} \exp \left[ - \frac{p_{4} (r - p_{3}s)^{2}}{p_{5} + s^{2}} \right]$$

Where the first form correspond to core interactions with s-type valence electrons and the second to core interactions with p-type valence electrons.

The current version adds full support for models with fixed-core and ECP definitions. to enable larger timesteps (i.e. by avoiding the high frequency vibrational modes -translational and radial- of the 2 s electrons), and in the ECP case to reduce the increased orbital complexity in higher Z elements (up to Z<18). A fixed-core should be defined with a mass that includes the corresponding nuclear mass plus the 2 s electrons in atomic mass units (2x5.4857990943e-4), and a radius equivalent to that of minimized 1s electrons (see examples under /examples/USER/eff/fixed-core). An pseudo-core should be described with a mass that includes the corresponding nuclear mass, plus all the core electrons (i.e no outer shell electrons), and a radius equivalent to that of a corresponding minimized full-electron system. The charge for a pseudo-core atom should be given by the number of outer shell electrons.

In general, eFF excels at computing the properties of materials in extreme conditions and tracing the system dynamics over multi-picosecond timescales; this is particularly relevant where electron excitations can change significantly the nature of bonding in the system. It can capture with surprising accuracy the behavior of such systems because it describes consistently and in an unbiased manner many different kinds of bonds, including covalent, ionic, multicenter, ionic, and plasma, and how they interconvert and/or change when they become excited. eFF also excels in computing the relative thermochemistry of isodemic reactions and conformational changes, where the bonds of the reactants are of the same type as the bonds of the products. eFF assumes that kinetic energy differences dominate the overall exchange energy, which is true when the electrons present are nearly spherical and nodeless and valid for covalent compounds such as dense hydrogen, hydrocarbons, and diamond; alkali metals (e.g. lithium), alkali earth metals (e.g. beryllium) and semimetals such as boron; and various compounds containing ionic and/or multicenter bonds, such as boron dihydride.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, the cutoff distance for the eff/cut style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

The pair_modify shift option is not relevant for these pair styles.

The eff/long (not yet available) style supports the pair_modify table option for tabulation of the short-range portion of the long-range Coulombic interaction.

These pair styles do not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

18.182. pair_style eff/cut command
These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

18.182.4 Restrictions

These pair styles will only be enabled if LAMMPS is built with the USER-EFF package. It will only be enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair styles require that particles store electron attributes such as radius, radial velocity, and radial force, as defined by the atom_style. The electron atom style does all of this.

These pair styles require you to use the comm_modify vel yes command so that velocities are stored by ghost atoms.

18.184.3 Description

Style `eim` computes pairwise interactions for ionic compounds using embedded-ion method (EIM) potentials (Zhou). The energy of the system $E$ is given by

$$ E = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=i}^{N} \phi_{ij} (r_{ij}) + \sum_{i=1}^{N} E_i (q_i, \sigma_i) $$

The first term is a double pairwise sum over the J neighbors of all I atoms, where $\phi_{ij}$ is a pair potential. The second term sums over the embedding energy $E_i$ of atom I, which is a function of its charge $q_i$ and the electrical potential $\sigma_i$ at its location. $E_i, q_i, \text{ and } \sigma_i$ are calculated as

$$ q_i = \sum_{j=1}^{N} \eta_{ji} (r_{ij}) $$

$$ \sigma_i = \sum_{j=1}^{N} q_j \cdot \psi_{ij} (r_{ij}) $$

$$ E_i (q_i, \sigma_i) = \frac{1}{2} \cdot q_i \cdot \sigma_i $$

where $\eta_{ji}$ is a pairwise function describing electron flow from atom I to atom J, and $\psi_{ij}$ is another pairwise function. The multi-body nature of the EIM potential is a result of the embedding energy term. A complete list of all the pair functions used in EIM is summarized below

$$ \phi_{ij} (r) = \begin{cases} 
\frac{E_{b,ij} \beta_{ij}}{\beta_{ij} - \alpha_{ij}} \exp \left(-\alpha_{ij} \frac{r - r_{e,ij}}{r_{e,ij}}\right) - \frac{E_{b,ij} \alpha_{ij}}{\beta_{ij} - \alpha_{ij}} \exp \left(-\beta_{ij} \frac{r - r_{e,ij}}{r_{e,ij}}\right) \cdot f_c (r, r_{e,ij}, r_{c,\phi,ij}), & p_{ij} = 1 \\
\frac{E_{b,ij} \beta_{ij}}{\beta_{ij} - \alpha_{ij}} \left(\frac{r_{e,ij}}{r}\right)^\alpha_{ij} - \frac{E_{b,ij} \alpha_{ij}}{\beta_{ij} - \alpha_{ij}} \left(\frac{r_{e,ij}}{r}\right)^\beta_{ij} \cdot f_c (r, r_{e,ij}, r_{c,\phi,ij}), & p_{ij} = 2 
\end{cases} $$

$$ \eta_{ij} = A_{\eta,ij} (\chi_j - \chi_i) \cdot f_c (r, r_{s,\eta,ij}, r_{c,\eta,ij}) $$

$$ \psi_{ij} (r) = A_{\psi,ij} \exp (-\zeta_{ij} r) \cdot f_c (r, r_{s,\psi,ij}, r_{c,\psi,ij}) $$

$$ f_c (r, r_p, r_c) = 0.510204 \cdot \text{erfc} \left[ \frac{1.64498 (2r - r_p - r_c)}{r_c - r_p} \right] - 0.010204 $$

Here $E_b, r_e, r(c, \phi), \alpha, \beta, A(\psi), \zeta, r(s, \psi), r(c, \psi), A(\eta), r(s, \eta), r(c, \eta), \chi$, and pair function type $p$ are parameters, with subscripts $ij$ indicating the two species of atoms in the atomic pair.

**Note:** Even though the EIM potential is treating atoms as charged ions, you should not use a LAMMPS `atom_style` that stores a charge on each atom and thus requires you to assign a charge to each atom, e.g. the `charge` or `full` atom styles. This is because the EIM potential infers the charge on an atom from the equation above for $q_i$; you do not assign charges explicitly.

All the EIM parameters are listed in a potential file which is specified by the `pair_coeff` command. This is an ASCII text file in a format described below. The “ffield.eim” file included in the “potentials” directory of the LAMMPS
distribution currently includes nine elements Li, Na, K, Rb, Cs, F, Cl, Br, and I. A system with any combination of these elements can be modeled. This file is parameterized in terms of LAMMPS metal units.

Note that unlike other potentials, cutoffs for EIM potentials are not set in the pair_style or pair_coeff command; they are specified in the EIM potential file itself. Likewise, the EIM potential file lists atomic masses; thus you do not need to use the mass command to specify them.

Only a single pair_coeff command is used with the eim style which specifies an EIM potential file and the element(s) to extract information for. The EIM elements are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- Elem1, Elem2, ...
- EIM potential file
- N element names = mapping of EIM elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example like one of those above, suppose you want to model a system with Na and Cl atoms. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Na, and the fourth to be Cl, you would use the following pair_coeff command:

```plaintext
pair_coeff * * Na Cl ffield.eim Na Na Na Cl
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The filename is the EIM potential file. The Na and Cl arguments (before the file name) are the two elements for which info will be extracted from the potential file. The first three trailing Na arguments map LAMMPS atom types 1,2,3 to the EIM Na element. The final Cl argument maps LAMMPS atom type 4 to the EIM Cl element.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an eim potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The ffield.eim file in the potentials directory of the LAMMPS distribution is formatted as follows:

Lines starting with # are comments and are ignored by LAMMPS. Lines starting with “global:” include three global values. The first value divides the cations from anions, i.e., any elements with electronegativity above this value are viewed as anions, and any elements with electronegativity below this value are viewed as cations. The second and third values are related to the cutoff function - i.e. the 0.510204, 1.64498, and 0.010204 shown in the above equation can be derived from these values.

Lines starting with “element:” are formatted as follows: name of element, atomic number, atomic mass, electronic negativity, atomic radius (LAMMPS ignores it), ionic radius (LAMMPS ignores it), cohesive energy (LAMMPS ignores it), and q0 (must be 0).

Lines starting with “pair:” are entered as: element 1, element 2, r_(c,phi), r_(c,phi) (redundant for historical reasons), E_b, r_e, alpha, beta, r_(c,eta), A_(eta), r_(s,eta), r_(c,psi), A_(psi), zeta, r_(s,psi), and p.

The lines in the file can be in any order; LAMMPS extracts the info it needs.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.
18.184.4 Restrictions

This style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package.

18.186.3 Description

Style \textit{exp6/rx} is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of \( m \) species whose reaction rate kinetics are determined from a set of \( n \) reaction rate equations through the \textit{fix rx} command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. The \textit{exp6/rx} style computes an exponential-6 potential given by

\[
U_{ij}(r) = \frac{\epsilon}{\alpha - 6} \left\{ 6 \exp[\alpha(1 - \frac{r_{ij}}{R_m})] - \alpha \left( \frac{R_m}{r_{ij}} \right)^6 \right\}
\]

where the \( \epsilon \) parameter determines the depth of the potential minimum located at \( R_m \), and \( \alpha \) determines the softness of the repulsion.

The coefficients must be defined for each species in a given particle type via the \textit{pair_coeff} command as in the examples above, where the first argument is the filename that includes the exponential-6 parameters for each species. The file includes the species tag followed by the \( \alpha, \epsilon \) and \( R_m \) parameters. The format of the file is described below.

The second and third arguments specify the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the \textit{fix rx} command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the \textit{fractional} or \textit{molecular} weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (\( u_{\text{Chem}} \)).

The fourth argument specifies the type of scaling that will be used to scale the EXP-6 parameters as reactions occur. Currently, there are three scaling options: \textit{exponent}, \textit{polynomial} and \textit{none}.

Exponent scaling requires two additional arguments for scaling the \( R_m \) and \( \epsilon \) parameters, respectively. The scaling factor is computed by \( \phi^{\text{exponent}} \), where \( \phi \) is the number of molecules represented by the coarse-grain particle and exponent is specified as a pair coefficient argument for \( R_m \) and \( \epsilon \), respectively. The \( R_m \) and \( \epsilon \) parameters are multiplied by the scaling factor to give the scaled interaction parameters for the CG particle.

Polynomial scaling requires a filename to be specified as a pair coeff argument. The file contains the coefficients to a fifth order polynomial for the \( \alpha \), \( \epsilon \) and \( R_m \) parameters that depend upon \( \phi \) (the number of molecules represented by the CG particle). The format of a polynomial file is provided below.

The \textit{none} option to the scaling does not have any additional pair coeff arguments. This is equivalent to specifying the \textit{exponent} option with \( R_m \) and \( \epsilon \) exponents of 0.0 and 0.0, respectively.

The final argument specifies the interaction cutoff (optional).

The format of a tabulated file is as follows (without the parenthesized comments):

```
# exponential-6 parameters for various species (one or more comment or blank lines)
h2o exp6 11.00 0.02 3.50 (species, exp6, alpha, Rm, epsilon)
no2 exp6 13.60 0.01 3.70
... co2 exp6 13.00 0.03 3.20
```

The format of the polynomial scaling file as follows (without the parenthesized comments):

```
# POLYNOMIAL FILE (one or more comment or blank lines)
```
General Functional Form:
\[ A \phi^5 + B \phi^4 + C \phi^3 + D \phi^2 + E \phi + F \]

Parameter A B C D E F

(alpha 0.0000 0.00000 0.0008 0.04955 -0.73804 13.63201
epsilon 0.0000 0.00478 -0.06283 0.24486 -0.33737 2.60097
rm 0.0001 -0.00118 -0.00253 0.05812 -0.00509 1.50106

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections.

Following a blank line, the next N lines list the species and their corresponding parameters. The first argument is the species tag, the second argument is the exp6 tag, the third argument is the \( \alpha \) parameter (energy units), the fourth argument is the \( \epsilon \) parameter (energy-distance^6 units), and the fifth argument is the \( R_m \) parameter (distance units). If a species tag of “1fluid” is listed as a pair coefficient, a one-fluid approximation is specified where a concentration-dependent combination of the parameters is computed through the following equations:

\[
R_{m}^{3} = \sum_{a} \sum_{b} x_{a}x_{b}R_{m,ab}^{3}
\]

\[
\epsilon = \frac{1}{R_{m}^{3}} \sum_{a} \sum_{b} x_{a}x_{b}\epsilon_{ab}R_{m,ab}^{3}
\]

\[
\alpha = \frac{1}{\epsilon R_{m}^{3}} \sum_{a} \sum_{b} x_{a}x_{b}\alpha_{ab}\epsilon_{ab}R_{m,ab}^{3}
\]

where

\[
\epsilon_{ab} = \sqrt{\epsilon_{a}\epsilon_{b}}
\]

\[
R_{m,ab} = \frac{R_{m,a} + R_{m,b}}{2}
\]

\[
\alpha_{ab} = \sqrt{\alpha_{a}\alpha_{b}}
\]

and \( x_{a} \) and \( x_{b} \) are the mole fractions of a and b, respectively, which comprise the gas mixture.

Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the pair_modify shift option for the energy of the exp() and 1/r^6 portion of the pair interaction.

This style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure for the A,C terms in the pair interaction.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
18.186.4 Restrictions

18.207.3 Description

These pair styles have a soft repulsive core, tunable by a parameter lambda, in order to avoid singularities during free energy calculations when sites are created or annihilated (Beutler). When lambda tends to 0 the pair interaction vanishes with a soft repulsive core. When lambda tends to 1, the pair interaction approaches the normal, non-soft potential. These pair styles are suited for “alchemical” free energy calculations using the fix adapt/fep and compute fep commands.

The lj/cut/soft style and related sub-styles compute the 12-6 Lennard-Jones and Coulomb potentials modified by a soft core, with the functional form

\[ E = \lambda^n 4\epsilon \left\{ \frac{1}{\alpha_{\text{LJ}}(1 - \lambda)^2 + \left( \frac{r}{\sigma} \right)^6} \right\} \quad r < r_c \]

The lj/class2/soft style is a 9-6 potential with the exponent of the denominator of the first term in brackets taking the value 1.5 instead of 2 (other details differ, see the form of the potential in pair_style lj/class2).

Coulomb interactions can also be damped with a soft core at short distance,

\[ E = \lambda^n \frac{C q_i q_j}{\epsilon [\alpha_C (1 - \lambda)^2 + r^2]^{1/2}} \quad r < r_c \]

In the Coulomb part C is an energy-conversion constant, \(q_i\) and \(q_j\) are the charges on the 2 atoms, and epsilon is the dielectric constant which can be set by the dielectric command.

The coefficient lambda is an activation parameter. When \(\lambda = 1\) the pair potential is identical to a Lennard-Jones term or a Coulomb term or a combination of both. When \(\lambda = 0\) the interactions are deactivated. The transition between these two extrema is smoothed by a soft repulsive core in order to avoid singularities in potential energy and forces when sites are created or annihilated and can overlap (Beutler).

The parameters \(n\), \(\alpha_{\text{LJ}}\) and \(\alpha_C\) are set in the pair_style command, before the cutoffs. Usual choices for the exponent are \(n = 2\) or \(n = 1\). For the remaining coefficients \(\alpha_{\text{LJ}} = 0.5\) and \(\alpha_C = 10 \text{ A}^2\) are appropriate choices. Plots of the 12-6 LJ and Coulomb terms are shown below, for lambda ranging from 1 to 0 every 0.1.
For the \textit{lj/cut/coul/cut/soft} or \textit{lj/cut/coul/long/soft} pair styles, as well as for the equivalent \textit{class2} versions, the following coefficients must be defined for each pair of atoms types via the \texttt{pair_coeff} command as in the examples above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- $\lambda$ (activation parameter, between 0 and 1)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter two coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the \texttt{pair_style} command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style \texttt{lj/cut/soft}, since it has no Coulombic terms. For the \texttt{coul/cut/soft} and \texttt{coul/long/soft} only lambda and the optional cutoff2 are to be specified.

Style \texttt{lj/cut/tip4p/long/soft} implements a soft-core version of the TIP4P water model. The usage of the TIP4P pair style is documented in the \texttt{pair_lj} styles. In the soft version the parameters $n$, $\alpha_{LJ}$ and $\alpha_C$ are set in the \texttt{pair_style} command, after the specific parameters of the TIP4P water model and before the cutoffs. The activation parameter lambda is supplied as an argument of the \texttt{pair_coeff} command, after epsilon and sigma and before the optional cutoffs.

Style \texttt{lj/charmm/coul/long/soft} implements a soft-core version of the modified 12-6 LJ potential used in CHARMM and documented in the \texttt{pair_style lj/charmm/coul/long} style. In the soft version the parameters $n$, $\alpha_{LJ}$ and $\alpha_C$ are set in the \texttt{pair_style} command, before the global cutoffs. The activation parameter lambda is introduced as an argument of the \texttt{pair_coeff} command, after $\epsilon$ and $\sigma$ and before the optional eps14 and sigma14.

Style \texttt{lj/class2/soft} implements a soft-core version of the 9-6 potential in \texttt{pair_style lj/class2}. In the soft version the parameters $n$, $\alpha_{LJ}$ and $\alpha_C$ are set in the \texttt{pair_style} command, before the global cutoffs. The activation parameter lambda is introduced as an argument of the \texttt{pair_coeff} command, after $\epsilon$ and $\sigma$ and before the optional cutoffs.

The \texttt{coul/cut/soft}, \texttt{coul/long/soft} and \texttt{tip4p/long/soft} sub-styles are designed to be combined with other pair potentials via the \texttt{pair_style hybrid/overlay} command. This is because they have no repulsive core. Hence, if used by themselves, there will be no repulsion to keep two oppositely charged particles from overlapping each other. In this case, if $\lambda = 1$, a singularity may occur. These sub-styles are suitable to represent charges embedded in the Lennard-Jones radius of another site (for example hydrogen atoms in several water models).
Note: When using the soft-core Coulomb potentials with long-range solvers (coul/long/soft, lj/cut/coul/long/soft, etc.) in a free energy calculation in which sites holding electrostatic charges are being created or annihilated (using fix adapt/fep and compute fep) it is important to adapt both the $\lambda$ activation parameter (from 0 to 1, or the reverse) and the value of the charge (from 0 to its final value, or the reverse). This ensures that long-range electrostatic terms (kspace) are correct. It is not necessary to use soft-core Coulomb potentials if the van der Waals site is present during the free-energy route, thus avoiding overlap of the charges. Examples are provided in the LAMMPS source directory tree, under examples/USER/fep.

Note: To avoid division by zero do not set $\sigma = 0$ in the lj/cut/soft and related styles; use the lambda parameter instead to activate/deactivate interactions, or use $\epsilon = 0$ and $\sigma = 1$. Alternatively, when sites do not interact though the Lennard-Jones term the coul/long/soft or similar sub-style can be used via the pair_style hybrid/overlay command.

The morse/soft variant modifies the pair_morse style at short range to have a soft core. The functional form differs from that of the lj/soft styles, and is instead given by:

$$s(\lambda) = \frac{(1 - \lambda)}{(1 - \lambda_f)}, \quad B = -2D e^{-2\alpha r_0}(e^{\alpha r_0} - 1)/3$$

$$E = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] + s(\lambda)B e^{-3\alpha(r-r_0)}, \quad \lambda \geq \lambda_f, \quad r < r_c$$

$$E = \left(D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] + Be^{-3\alpha(r-r_0)} \right) \left(\lambda/\lambda_f\right)^n, \quad \lambda < \lambda_f, \quad r < r_c$$

The morse/soft style requires the following pair coefficients:

- $D_0$ (energy units)
- $\alpha$ (1/distance units)
- $r_0$ (distance units)
- $\lambda$ (unitless, between 0.0 and 1.0)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global morse cutoff is used.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, tail correction, restart info:

The different versions of the lj/cut/soft pair styles support mixing. For atom type pairs IJ and I != J, the $\epsilon$ and $\sigma$ coefficients and cutoff distance for these pair style can be mixed. The default mix value is geometric for 12-6 styles.
The mixing rule for epsilon and sigma for lj/class2/soft 9-6 potentials is to use the sixthpower formulas. The pair_modify mix setting is thus ignored for class2 potentials for $\epsilon$ and $\sigma$. However it is still followed for mixing the cutoff distance. See the pair_modify command for details.

The morse/soft pair style does not support mixing. Thus, coefficients for all LJ pairs must be specified explicitly.

All of the pair styles with soft core support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction.

The different versions of the lj/cut/soft pair styles support the pair_modify tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

**Note:** The analytical form of the tail corrections for energy and pressure used in the lj/cut/soft potentials are approximate, being identical to that of the corresponding non-soft potentials scaled by a factor $\lambda^n$. The errors due to this approximation should be negligible. For example, for a cutoff of $2.5\sigma$ this approximation leads to maximum relative errors in tail corrections of the order of $1e-4$ for energy and virial ($\alpha_{\text{LJ}} = 0.5, n = 2$). The error vanishes when lambda approaches 0 or 1. Note that these are the errors affecting the long-range tail (itself a correction to the interaction energy) which includes other approximations, namely that the system is homogeneous (local density equal the average density) beyond the cutoff.

The morse/soft pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

All of these pair styles write information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

### 18.207.4 Restrictions

The pair styles with soft core are only enabled if LAMMPS was built with the USER-FEP package. The long versions also require the KSPACE package to be installed. The soft tip4p versions also require the MOLECULE package to be installed. These styles are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

### 18.207.5 Related commands

18.209 pair_style gauss/gpu command

18.210 pair_style gauss/omp command

18.211 pair_style gauss/cut command

18.212 pair_style gauss/cut/omp command

18.212.1 Syntax

```
pair_style gauss cutoff
pair_style gauss/cut cutoff
```

- cutoff = global cutoff for Gauss interactions (distance units)

18.212.2 Examples

```
pair_style gauss 12.0
pair_coeff * * 1.0 0.9
pair_coeff 1 4 1.0 0.9 10.0

pair_style gauss/cut 3.5
pair_coeff 1 4 0.2805 1.45 0.112
```

18.212.3 Description

Style `gauss` computes a tethering potential of the form

\[ E = -A \exp(-Br^2) \quad r < r_c \]

between an atom and its corresponding tether site which will typically be a frozen atom in the simulation. \( r_c \) is the cutoff.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- A (energy units)
- B (1/distance^2 units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

Style `gauss/cut` computes a generalized Gaussian interaction potential between pairs of particles:

\[ E = \frac{H}{\sigma_h \sqrt{2\pi}} \exp \left[ -\frac{(r - r_{mh})^2}{2\sigma_h^2} \right] \]
where H determines together with the standard deviation $\sigma_h$ the peak height of the Gaussian function, and $r_{mh}$ the peak position. Examples of the use of the Gaussian potentials include implicit solvent simulations of salt ions (Lenart) and of surfactants (Jusufi). In these instances the Gaussian potential mimics the hydration barrier between a pair of particles. The hydration barrier is located at $r_{mh}$ and has a width of $\sigma_h$. The prefactor determines the height of the potential barrier.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- H (energy * distance units)
- $r_{mh}$ (distance units)
- $\sigma_h$ (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I != J, the A, B, H, sigma_h, r_mh parameters, and the cutoff distance for these pair styles can be mixed: A (energy units) sqrt(1/B) (distance units, see below) H (energy units) sigma_h (distance units) r_mh (distance units) cutoff (distance units):ul

The default mix value is geometric. Only arithmetic and geometric mix values are supported. See the “pair_modify” command for details.

The A and H parameters are mixed using the same rules normally used to mix the “epsilon” parameter in a Lennard Jones interaction. The sigma_h, r_mh, and the cutoff distance are mixed using the same rules used to mix the “sigma” parameter in a Lennard Jones interaction. The B parameter is converted to a distance (sigma), before mixing (using sigma=B^-0.5), and converted back to a coefficient afterwards (using B=sigma^2). Negative A values are converted to positive A values (using abs(A)) before mixing, and converted back after mixing (by multiplying by min(sign(Ai),sign(Aj))). This way, if either particle is repulsive (if Ai<0 or Aj<0), then the default interaction between both particles will be repulsive.

The gauss style does not support the `pair_modify` shift option. There is no effect due to the Gaussian well beyond the cutoff; hence reasonable cutoffs need to be specified.

The gauss/cut style supports the `pair_modify` shift option for the energy of the Gauss-potential portion of the pair interaction.

The `pair_modify` table and tail options are not relevant for these pair styles.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.
These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

The gauss pair style tallies an “occupancy” count of how many Gaussian-well sites have an atom within the distance at which the force is a maximum = sqrt(0.5/h). This quantity can be accessed via the compute pair command as a vector of values of length 1.

To print this quantity to the log file (with a descriptive column heading) the following commands could be included in an input script:

```plaintext
compute gauss all pair gauss
variable occ equal c_gauss[1]
thermo_style custom step temp epair v_occ
```

18.212.4 Restrictions

The gauss/cut style is part of the “user-misc” package. It is only enabled if LAMMPS is build with that package. See the Build package doc page for more info.

```

• gamma = shift for potential minimum (typically 1)
• upsilon = exponent for eta orientation-dependent energy function
• mu = exponent for chi orientation-dependent energy function
• cutoff = global cutoff for interactions (distance units)
18.216.2 Examples

pair_style gayberne 1.0 1.0 1.0 10.0
pair_coeff * * 1.0 1.7 1.7 3.4 3.4 1.0 1.0 1.0

18.216.3 Description

The gayberne styles compute a Gay-Berne anisotropic LJ interaction (Berardi) between pairs of ellipsoidal particles or an ellipsoidal and spherical particle via the formulas

\[ U(A_1, A_2, r_{12}) = U_r(A_1, A_2, r_{12}, \gamma) \cdot \eta_{12}(A_1, A_2, \nu) \cdot \chi_{12}(A_1, A_2, r_{12}, \mu) \]
\[ U_r = 4\epsilon (\varrho^{12} - \varrho^6) \]
\[ \varrho = \frac{h_{12}}{\sigma + \gamma\sigma} \]

where A1 and A2 are the transformation matrices from the simulation box frame to the body frame and r_{12} is the center to center vector between the particles. U_r controls the shifted distance dependent interaction based on the distance of closest approach of the two particles (h_{12}) and the user-specified shift parameter gamma. When both particles are spherical, the formula reduces to the usual Lennard-Jones interaction (see details below for when Gay-Berne treats a particle as “spherical”).

For large uniform molecules it has been shown that the energy parameters are approximately representable in terms of local contact curvatures (Everaers):

\[ \epsilon_a = \sigma \cdot \frac{a}{b \cdot c} ; \epsilon_b = \sigma \cdot \frac{b}{a \cdot c} ; \epsilon_c = \sigma \cdot \frac{c}{a \cdot b} \]

The variable names utilized as potential parameters are for the most part taken from (Everaers) in order to be consistent with the RE-squared pair potential. Details on the upsilon and mu parameters are given here.

More details of the Gay-Berne formulation are given in the references listed below and in this supplementary document.

Use of this pair style requires the NVE, NVT, or NPT fixes with the asphere extension (e.g. fix nve/asphere) in order to integrate particle rotation. Additionally, atom_style ellipsoid should be used since it defines the rotational state and the size and shape of each ellipsoidal particle.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- \( \epsilon \) = well depth (energy units)
- \( \sigma \) = minimum effective particle radii (distance units)
- \( \epsilon_{i,a} \) = relative well depth of type I for side-to-side interactions
- \( \epsilon_{i,b} \) = relative well depth of type I for face-to-face interactions
- \( \epsilon_{i,c} \) = relative well depth of type I for end-to-end interactions
- \( \epsilon_{j,a} \) = relative well depth of type J for side-to-side interactions
- \( \epsilon_{j,b} \) = relative well depth of type J for face-to-face interactions
- \( \epsilon_{j,c} \) = relative well depth of type J for end-to-end interactions
- cutoff (distance units)
The last coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used.

It is typical with the Gay-Berne potential to define $\sigma$ as the minimum of the 3 shape diameters of the particles involved in an I,I interaction, though this is not required. Note that this is a different meaning for $\sigma$ than the pair_style resquared potential uses.

The $\epsilon_i$ and $\epsilon_j$ coefficients are actually defined for atom types, not for pairs of atom types. Thus, in a series of pair_coeff commands, they only need to be specified once for each atom type.

Specifically, if any of $\epsilon_{i,a}$, $\epsilon_{i,b}$, $\epsilon_{i,c}$ are non-zero, the three values are assigned to atom type I. If all the $\epsilon_i$ values are zero, they are ignored. If any of $\epsilon_{j,a}$, $\epsilon_{j,b}$, $\epsilon_{j,c}$ are non-zero, the three values are assigned to atom type J. If all three epsilon_j values are zero, they are ignored. Thus the typical way to define the $\epsilon_i$ and $\epsilon_j$ coefficients is to list their values in "pair_coeff I J" commands when I = J, but set them to 0.0 when I != J. If you do list them when I != J, you should insure they are consistent with their values in other pair_coeff commands, since only the last setting will be in effect.

Note that if this potential is being used as a sub-style of pair_style hybrid, and there is no "pair_coeff I I" setting made for Gay-Berne for a particular type I (because I-I interactions are computed by another hybrid pair potential), then you still need to insure the $\epsilon$ a,b,c coefficients are assigned to that type. e.g. in a "pair_coeff I J" command.

Note: If the $\epsilon$ a = b = c for an atom type, and if the shape of the particle itself is spherical, meaning its 3 shape parameters are all the same, then the particle is treated as an LJ sphere by the Gay-Berne potential. This is significant because if two LJ spheres interact, then the simple Lennard-Jones formula is used to compute their interaction energy(force using the specified epsilon and sigma as the standard LJ parameters. This is much cheaper to compute than the full Gay-Berne formula. To treat the particle as a LJ sphere with sigma = D, you should normally set $\epsilon$ a = b = c = 1.0, set the pair_coeff $\sigma$ = D, and also set the 3 shape parameters for the particle to D. The one exception is that if the 3 shape parameters are set to 0.0, which is a valid way in LAMMPS to specify a point particle, then the Gay-Berne potential will treat that as shape parameters of 1.0 (i.e. a LJ particle with $\sigma$ = 1), since it requires finite-size particles. In this case you should still set the pair_coeff $\sigma$ to 1.0 as well.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair styles supports the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction, but only for sphere-sphere interactions. There is no shifting performed for ellipsoidal interactions due to the anisotropic dependence of the interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.
This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

### 18.216.4 Restrictions

The gayberne style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair style require that atoms store torque and a quaternion to represent their orientation, as defined by the atom_style. It also require they store a per-type shape. The particles cannot store a per-particle diameter.

This pair style requires that atoms be ellipsoids as defined by the atom_style ellipsoid command.

Particles acted on by the potential can be finite-size aspherical or spherical particles, or point particles. Spherical particles have all 3 of their shape parameters equal to each other. Point particles have all 3 of their shape parameters equal to 0.0.

The Gay-Berne potential does not become isotropic as r increases (Everaers). The distance-of-closest-approach approximation used by LAMMPS becomes less accurate when high-aspect ratio ellipsoids are used.

18.221 pair_style gran/hooke/history/kk command

18.222 pair_style gran/hertz/history command

18.223 pair_style gran/hertz/history/omp command

18.223.1 Syntax

```
pair_style style Kn Kt gamma_n gamma_t xmu dampflag
```

- style = gran/hooke or gran/hooke/history or gran/hertz/history
- Kn = elastic constant for normal particle repulsion (force/distance units or pressure units - see discussion below)
- Kt = elastic constant for tangential contact (force/distance units or pressure units - see discussion below)
- gamma_n = damping coefficient for collisions in normal direction (1/time units or 1/time-distance units - see discussion below)
- gamma_t = damping coefficient for collisions in tangential direction (1/time units or 1/time-distance units - see discussion below)
- xmu = static yield criterion (unitless value between 0.0 and 1.0e4)
- dampflag = 0 or 1 if tangential damping force is excluded or included

**Note:** Versions of LAMMPS before 9Jan09 had different style names for granular force fields. This is to emphasize the fact that the Hertzian equation has changed to model polydispersity more accurately. A side effect of the change is that the Kn, Kt, gamma_n, and gamma_t coefficients in the pair_style command must be specified with different values in order to reproduce calculations made with earlier versions of LAMMPS, even for monodisperse systems. See the NOTE below for details.
18.223.2 Examples

```
pair_style  gran/hooke/history  200000.0  NULL  50.0  NULL  0.5  1
pair_style  gran/hooke     200000.0  70000.0  50.0  30.0  0.5  0
```

18.223.3 Description

The \textit{gran} styles use the following formulas for the frictional force between two granular particles, as described in (Brilliantov), (Silbert), and (Zhang), when the distance \( r \) between two particles of radii \( R_i \) and \( R_j \) is less than their contact distance \( d = R_i + R_j \). There is no force between the particles when \( r > d \).

The two Hookean styles use this formula:

\[
F_{hk} = (k_n \delta n_{ij} - m_{eff} \gamma_n v_n) - (k_t \Delta s_t + m_{eff} \gamma_t v_t)
\]

The Hertzian style uses this formula:

\[
F_{hz} = \sqrt{\delta} \sqrt{\frac{R_i R_j}{R_i + R_j}} F_{hk} = \sqrt{\delta} \sqrt{\frac{R_i R_j}{R_i + R_j}} \left( (k_n \delta n_{ij} - m_{eff} \gamma_n v_n) - (k_t \Delta s_t + m_{eff} \gamma_t v_t) \right)
\]

In both equations the first parenthesized term is the normal force between the two particles and the second parenthesized term is the tangential force. The normal force has 2 terms, a contact force and a damping force. The tangential force also has 2 terms: a shear force and a damping force. The shear force is a “history” effect that accounts for the tangential displacement between the particles for the duration of the time they are in contact. This term is included in pair styles \textit{hooke/history} and \textit{hertz/history}, but is not included in pair style \textit{hooke}. The tangential damping force term is included in all three pair styles if \textit{dampflag} is set to 1; it is not included if \textit{dampflag} is set to 0.

The other quantities in the equations are as follows:

- \( \delta = d - r \) = overlap distance of 2 particles
- \( K_n \) = elastic constant for normal contact
- \( K_t \) = elastic constant for tangential contact
- \( \gamma_n \) = viscoelastic damping constant for normal contact
- \( \gamma_t \) = viscoelastic damping constant for tangential contact
- \( m_{eff} = M_i M_j / (M_i + M_j) \) = effective mass of 2 particles of mass \( M_i \) and \( M_j \)
- \( \Delta s_t \) = tangential displacement vector between 2 particles which is truncated to satisfy a frictional yield criterion
- \( n_{ij} \) = unit vector along the line connecting the centers of the 2 particles
- \( V_n \) = normal component of the relative velocity of the 2 particles
- \( V_t \) = tangential component of the relative velocity of the 2 particles

The \( K_n, K_t, \gamma_n, \) and \( \gamma_t \) coefficients are specified as parameters to the pair_style command. If a NULL is used for \( K_t \), then a default value is used where \( K_t = 2/7 K_n \). If a NULL is used for \( \gamma_t \), then a default value is used where \( \gamma_t = 1/2 \gamma_n \).

The interpretation and units for these 4 coefficients are different in the Hookean versus Hertzian equations.

The Hookean model is one where the normal push-back force for two overlapping particles is a linear function of the overlap distance. Thus the specified \( K_n \) is in units of \((\text{force/distance})\). Note that this push-back force is independent of absolute particle size (in the monodisperse case) and of the relative sizes of the two particles (in the polydisperse case). This model also applies to the other terms in the force equation so that the specified \( \gamma_n \) is in units of \((1/\text{time})\), \( K_t \) is in units of \((\text{force/distance})\), and \( \gamma_t \) is in units of \((1/\text{time})\).
The Hertzian model is one where the normal push-back force for two overlapping particles is proportional to the area of overlap of the two particles, and is thus a non-linear function of overlap distance. Thus $K_n$ has units of force per area and is thus specified in units of (pressure). The effects of absolute particle size (monodispersity) and relative size (polydispersity) are captured in the radii-dependent pre-factors. When these pre-factors are carried through to the other terms in the force equation it means that the specified $\gamma_n$ is in units of $(1/(time*distance))$, $K_t$ is in units of (pressure), and $\gamma_t$ is in units of $(1/(time*distance))$.

Note that in the Hookean case, $K_n$ can be thought of as a linear spring constant with units of force/distance. In the Hertzian case, $K_n$ is like a non-linear spring constant with units of force/area or pressure, and as shown in the (Zhang) paper, $K_n = 4G/(3(1 - \nu))$ where $\nu$ = the Poisson ratio, $G$ = shear modulus = $E/(2(1 + \nu))$, and $E$ = Young’s modulus. Similarly, $K_t = 4G/(2 - \nu)$. (NOTE: in an earlier version of the manual, we incorrectly stated that $K_t = 8G/(2 - \nu)$.)

Thus in the Hertzian case $K_n$ and $K_t$ can be set to values that corresponds to properties of the material being modeled. This is also true in the Hookean case, except that a spring constant must be chosen that is appropriate for the absolute size of particles in the model. Since relative particle sizes are not accounted for, the Hookean styles may not be a suitable model for polydisperse systems.

Note: In versions of LAMMPS before 9Jan09, the equation for Hertzian interactions did not include the $\sqrt{r_ir_j/(r_i + r_j)}$ term and thus was not as accurate for polydisperse systems. For monodisperse systems, $\sqrt{r_ir_j/(r_i + r_j)}$ is a constant factor that effectively scales all 4 coefficients: $K_n, K_t, \gamma_n, \gamma_t$. Thus you can set the values of these 4 coefficients appropriately in the current code to reproduce the results of a previous Hertzian monodisperse calculation. For example, for the common case of a monodisperse system with particles of diameter 1, all 4 of these coefficients should now be set 2x larger than they were previously.

Xmu is also specified in the pair_style command and is the upper limit of the tangential force through the Coulomb criterion $F_t = \mu*xmu*F_n$, where $F_t$ and $F_n$ are the total tangential and normal force components in the formulas above. Thus in the Hookean case, the tangential force between 2 particles grows according to a tangential spring and dash-pot model until $F_t/F_n = \mu*xmu$ and is then held at $F_t = F_n*\mu*xmu$ until the particles lose contact. In the Hertzian case, a similar analogy holds, though the spring is no longer linear.

Note: Normally, xmu should be specified as a fractional value between 0.0 and 1.0, however LAMMPS allows large values (up to 1.0e4) to allow for modeling of systems which can sustain very large tangential forces.

The effective mass $m_{eff}$ is given by the formula above for two isolated particles. If either particle is part of a rigid body, its mass is replaced by the mass of the rigid body in the formula above. This is determined by searching for a fix rigid command (or its variants).

For granular styles there are no additional coefficients to set for each pair of atom types via the pair_coeff command. All settings are global and are made via the pair_style command. However you must still use the pair_coeff for all pairs of granular atom types. For example the command

```
pair_coeff * *
```

should be used if all atoms in the simulation interact via a granular potential (i.e. one of the pair styles above is used). If a granular potential is used as a sub-style of pair_style hybrid, then specific atom types can be used in the pair_coeff command to determine which atoms interact via a granular potential.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

The pair_modify mix, shift, table, and tail options are not relevant for granular pair styles.

These pair styles write their information to binary restart files, so a pair_style command does not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

The single() function of these pair styles returns 0.0 for the energy of a pairwise interaction, since energy is not conserved in these dissipative potentials. It also returns only the normal component of the pairwise interaction force. However, the single() function also calculates 10 extra pairwise quantities. The first 3 are the components of the tangential force between particles I and J, acting on particle I. The fourth is the magnitude of this tangential force. The next 3 (5-7) are the components of the relative velocity in the normal direction (along the line joining the 2 sphere centers). The last 3 (8-10) the components of the relative velocity in the tangential direction.

These extra quantities can be accessed by the compute pair/local command, as p1, p2, ..., p10.

18.223.4 Restrictions

All the granular pair styles are part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair styles require that atoms store torque and angular velocity (omega) as defined by the atom_style. They also require a per-particle radius is stored. The sphere atom style does all of this.

This pair style requires you to use the comm_modify vel yes command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the read_restart command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the read_restart command for more details.

18.224.3 Description

The granular styles support a variety of options for the normal, tangential, rolling and twisting forces resulting from contact between two granular particles. This expands on the options offered by the pair gran/* pair styles. The total computed forces and torques are the sum of various models selected for the normal, tangential, rolling and twisting modes of motion.

All model choices and parameters are entered in the pair_coeff command, as described below. Unlike e.g. pair gran/hooke, coefficient values are not global, but can be set to different values for different combinations of particle types, as determined by the pair_coeff command. If the contact model choice is the same for two particle types, the mixing for the cross-coefficients can be carried out automatically. This is shown in the last example, where model choices are the same for type 1 - type 1 as for type 2 - type2 interactions, but coefficients are different. In this case, the mixed coefficients for type 1 - type 2 interactions can be determined from mixing rules discussed below. For additional flexibility, coefficients as well as model forms can vary between particle types, as shown in the fourth example: type 1 - type 1 interactions are based on a Johnson-Kendall-Roberts normal contact model and 2-2 interactions are based on a DMT cohesive model (see below). In that example, 1-1 and 2-2 interactions have different model forms, in which
case mixing of coefficients cannot be determined, so 1-2 interactions must be explicitly defined via the pair_coeff 1 * command, otherwise an error would result.

The first required keyword for the pair_coeff command is the normal contact model. Currently supported options for normal contact models and their required arguments are:

1. **hooke**: \( k_n, \eta_{n0} \) (or \( e \))
2. **hertz**: \( k_n, \eta_{n0} \) (or \( e \))
3. **hertz/material**: \( E, \eta_{n0} \) (or \( e \)), \( \nu \)
4. **dmt**: \( E, \eta_{n0} \) (or \( e \)), \( \nu, \gamma \)
5. **jkr**: \( E, \eta_{n0} \) (or \( e \)), \( \nu, \gamma \)

Here, \( k_n \) is spring stiffness (with units that depend on model choice, see below); \( \eta_{n0} \) is a damping prefactor (or, in its place a coefficient of restitution \( e \), depending on the choice of damping mode, see below); \( E \) is Young’s modulus in units of force/length^2, i.e. pressure; \( \nu \) is Poisson’s ratio and \( \gamma \) is a surface energy density, in units of energy/length^2.

For the **hooke** model, the normal, elastic component of force acting on particle \( i \) due to contact with particle \( j \) is given by:

\[
F_{ne,Hooke} = k_N \delta_{ij} n
\]

Where \( \delta_{ij} = R_i + R_j - \|r_{ij}\| \) is the particle overlap, \( R_i, R_j \) are the particle radii, \( r_{ij} = r_i - r_j \) is the vector separating the two particle centers (note the i-j ordering so that \( F_{ne} \) is positive for repulsion), and \( n = \frac{r_{ij}}{\|r_{ij}\|} \). Therefore, for **hooke**, the units of the spring constant \( k_n \) are force/distance, or equivalently mass/time^2.

For the **hertz** model, the normal component of force is given by:

\[
F_{ne,Hertz} = k_N R_{eff}^{1/2} \delta_{ij}^{3/2} n
\]

Here, \( R_{eff} = \frac{R_i R_j}{R_i + R_j} \) is the effective radius, denoted for simplicity as \( R \) from here on. For **hertz**, the units of the spring constant \( k_n \) are force/length^2, or equivalently pressure.

For the **hertz/material** model, the force is given by:

\[
F_{ne,Hertz/material} = 4 R_{eff}^{1/2} \delta_{ij}^{3/2} n
\]

Here, \( E_{eff} = E = \left( \frac{1-\nu_i^2}{E_i} + \frac{1-\nu_j^2}{E_j} \right)^{-1} \) is the effective Young’s modulus, with \( \nu_i, \nu_j \) the Poisson ratios of the particles of types \( i \) and \( j \). Note that if the elastic modulus and the shear modulus of the two particles are the same, the **hertz/material** model is equivalent to the **hertz** model with \( k_N = 4/3E_{eff} \).

The **dmt** model corresponds to the (Derjaguin-Muller-Toporov) cohesive model, where the force is simply Hertz with an additional attractive cohesion term:

\[
F_{ne,dmt} = \left( \frac{4}{3} E R^{1/2} \delta_{ij}^{3/2} - 4\pi \gamma R \right) n
\]

The **jkr** model is the (Johnson-Kendall-Roberts) model, where the force is computed as:

\[
F_{ne,jkr} = \left( \frac{4 E a^3}{3 R} - 2\pi a^2 \sqrt{\frac{4\gamma E}{\pi a}} \right) n
\]

Here, \( a \) is the radius of the contact zone, related to the overlap \( \delta \) according to:

\[
\delta = a^2 / R - 2\sqrt{\pi \gamma a / E}
\]
LAMMPS internally inverts the equation above to solve for \( a \) in terms of \( \delta \), then solves for the force in the previous equation. Additionally, note that the JKR model allows for a tensile force beyond contact (i.e. for \( \delta < 0 \)), up to a maximum of \( 3\pi \gamma R \) (also known as the ‘pull-off’ force). Note that this is a hysteretic effect, where particles that are not contacting initially will not experience force until they come into contact \( \delta \geq 0 \); as they move apart and \( \delta < 0 \), they experience a tensile force up to \( 3\pi \gamma R \), at which point they lose contact.

In addition, the normal force is augmented by a damping term of the following general form:

\[
F_{n,damp} = -\eta_n v_{n,rel}
\]

Here, \( v_{n,rel} = (v_j - v_i) \cdot n \) is the component of relative velocity along \( n \).

The optional damping keyword to the pair_coeff command followed by a keyword determines the model form of the damping factor \( \eta_n \), and the interpretation of the \( \eta_{n0} \) or \( e \) coefficients specified as part of the normal contact model settings. The damping keyword and corresponding model form selection may be appended anywhere in the pair coeff command. Note that the choice of damping model affects both the normal and tangential damping (and depending on other settings, potentially also the twisting damping). The options for the damping model currently supported are:

1. velocity
2. mass_velocity
3. viscoelastic
4. tsuji

If the damping keyword is not specified, the viscoelastic model is used by default.

For damping velocity, the normal damping is simply equal to the user-specified damping coefficient in the normal model:

\[
\eta_n = \eta_{n0}
\]

Here, \( \eta_{n0} \) is the damping coefficient specified for the normal contact model, in units of mass/time.

For damping mass_velocity, the normal damping is given by:

\[
\eta_n = \eta_{n0} m_{eff}
\]

Here, \( \eta_{n0} \) is the damping coefficient specified for the normal contact model, in units of mass/time and \( m_{eff} = m_i m_j / (m_i + m_j) \) is the effective mass. Use damping mass_velocity to reproduce the damping behavior of pair gran/hooke/*.

The damping viscoelastic model is based on the viscoelastic treatment of (Brilliantov et al), where the normal damping is given by:

\[
\eta_n = \eta_{n0} a m_{eff}
\]

Here, \( a \) is the contact radius, given by \( a = \sqrt{R\delta} \) for all models except jkr, for which it is given implicitly according to \( \delta = a^2 / R - 2\sqrt{\pi\gamma a / E} \). For damping viscoelastic, \( \eta_{n0} \) is in units of 1/(time*distance).

The tsuji model is based on the work of (Tsuji et al). Here, the damping coefficient specified as part of the normal model is interpreted as a restitution coefficient \( e \). The damping constant \( \eta_n \) is given by:

\[
\eta_n = \alpha (m_{eff} k_n)^{1/2}
\]

For normal contact models based on material parameters, \( k_n = 4/3Ea \). The parameter \( \alpha \) is related to the restitution coefficient \( e \) according to:

\[
\alpha = 1.2728 - 4.2783e + 11.087e^2 - 22.348e^3 + 27.467e^4 - 18.022e^5 + 4.8218e^6
\]
The dimensionless coefficient of restitution $e$ specified as part of the normal contact model parameters should be between 0 and 1, but no error check is performed on this.

The total normal force is computed as the sum of the elastic and damping components:

$$F_n = F_{ne} + F_{n,damp}$$

The pair_coeff command also requires specification of the tangential contact model. The required keyword tangential is expected, followed by the model choice and associated parameters. Currently supported tangential model choices and their expected parameters are as follows:

1. linear_nohistory : $x_{\gamma,t}$, $\mu_s$
2. linear_history : $k_t$, $x_{\gamma,t}$, $\mu_s$
3. mindlin : $k_t$ or NULL, $x_{\gamma,t}$, $\mu_s$
4. mindlin_rescale : $k_t$ or NULL, $x_{\gamma,t}$, $\mu_s$

Here, $x_{\gamma,t}$ is a dimensionless multiplier for the normal damping $\eta_n$ that determines the magnitude of the tangential damping, $\mu_t$ is the tangential (or sliding) friction coefficient, and $k_t$ is the tangential stiffness coefficient.

For tangential linear_nohistory, a simple velocity-dependent Coulomb friction criterion is used, which mimics the behavior of the pair gran/hooke style. The tangential force ($\mathbf{F}_t$) is given by:

$$\mathbf{F}_t = -\min(\mu_t F_{n0}, \|\mathbf{F}_{t,damp}\|) \mathbf{t}$$

The tangential damping force $\mathbf{F}_{t,damp}$ is given by:

$$\mathbf{F}_{t,damp} = -\eta_t \mathbf{v}_{t,rel}$$

The tangential damping prefactor $\eta_t$ is calculated by scaling the normal damping $\eta_n$ (see above):

$$\eta_t = -x_{\gamma,t} \eta_n$$

The normal damping prefactor $\eta_n$ is determined by the choice of the damping keyword, as discussed above. Thus, the damping keyword also affects the tangential damping. The parameter $x_{\gamma,t}$ is a scaling coefficient. Several works in the literature use $x_{\gamma,t} = 1$ (Marshall, Tsuji et al, Silbert et al). The relative tangential velocity at the point of contact is given by $\mathbf{v}_{t,rel} = \mathbf{v}_t - (R_i \Omega_i + R_j \Omega_j) \times \mathbf{n}$, where $\mathbf{v}_t = \mathbf{v}_r - \mathbf{v}_r \cdot \mathbf{n}$, $\mathbf{v}_r = \mathbf{v}_j - \mathbf{v}_i$. The direction of the applied force is $\mathbf{t} = \mathbf{v}_{t,rel}/\|\mathbf{v}_{t,rel}\|$.

The normal force value $F_{n0}$ used to compute the critical force depends on the form of the contact model. For non-cohesive models (hertz, hertz/material, hooke), it is given by the magnitude of the normal force:

$$F_{n0} = \|\mathbf{F}_n\|$$

For cohesive models such as jkr and dmt, the critical force is adjusted so that the critical tangential force approaches $\mu_t F_{pulloff}$, see Marshall, equation 43, and Thornton. For both models, $F_{n0}$ takes the form:

$$F_{n0} = \|\mathbf{F}_ne + 2F_{pulloff}\|$$

Where $F_{pulloff} = 3\pi\gamma R$ for jkr, and $F_{pulloff} = 4\pi\gamma R$ for dmt.

The remaining tangential options all use accumulated tangential displacement (i.e. contact history). This is discussed below in the context of the linear_history option, but the same treatment of the accumulated displacement applies to the other options as well.
For *tangential linear_history*, the tangential force is given by:

\[ \mathbf{F}_t = -\min(\mu_t \mathbf{F}_n, || - k_t \xi + \mathbf{F}_{t,damp}||) \mathbf{t} \]

Here, \( \xi \) is the tangential displacement accumulated during the entire duration of the contact:

\[ \xi = \int_{t_0}^{t} \mathbf{v}_{t,rel}(\tau)d\tau \]

This accumulated tangential displacement must be adjusted to account for changes in the frame of reference of the contacting pair of particles during contact. This occurs due to the overall motion of the contacting particles in a rigid-body-like fashion during the duration of the contact. There are two modes of motion that are relevant: the ‘tumbling’ rotation of the contacting pair, which changes the orientation of the plane in which tangential displacement occurs; and ‘spinning’ rotation of the contacting pair about the vector connecting their centers of mass (\( \mathbf{n} \)). Corrections due to the former mode of motion are made by rotating the accumulated displacement into the plane that is tangential to the contact vector at each step, or equivalently removing any component of the tangential displacement that lies along \( \mathbf{n} \), and rescaling to preserve the magnitude. This follows the discussion in *Luding*, see equation 17 and relevant discussion in that work:

\[ \xi = (\xi' - (\mathbf{n} \cdot \xi')\mathbf{n}) \frac{||\xi'||}{||\xi'|| - \mathbf{n} \cdot \xi'} \]

Here, \( \xi' \) is the accumulated displacement prior to the current time step and \( \xi \) is the corrected displacement. Corrections to the displacement due to the second mode of motion described above (rotations about \( \mathbf{n} \)) are not currently implemented, but are expected to be minor for most simulations.

Furthermore, when the tangential force exceeds the critical force, the tangential displacement is re-scaled to match the value for the critical force (see *Luding*, equation 20 and related discussion):

\[ \xi = -\frac{1}{k_t} (\mu_t \mathbf{F}_n + \mathbf{F}_{t,\text{damp}}) \]

The tangential force is added to the total normal force (elastic plus damping) to produce the total force on the particle. The tangential force also acts at the contact point (defined as the center of the overlap region) to induce a torque on each particle according to:

\[ \tau_i = -(R_i - 0.5\delta)\mathbf{n} \times \mathbf{F}_t \]
\[ \tau_j = -(R_j - 0.5\delta)\mathbf{n} \times \mathbf{F}_t \]

For *tangential mindlin*, the *Mindlin* no-slip solution is used, which differs from the *linear_history* option by an additional factor of \( a \), the radius of the contact region. The tangential force is given by:

\[ \mathbf{F}_t = -\min(\mu_t \mathbf{F}_n, || - k_t a \xi + \mathbf{F}_{t,damp}||) \mathbf{t} \]

Here, \( a \) is the radius of the contact region, given by \( a = \sqrt{R\delta} \) for all normal contact models, except for *jkr*, where it is given implicitly by \( \delta = a^2/R - 2\sqrt{\pi\gamma a}/\mathcal{E} \), see discussion above. To match the Mindlin solution, one should set \( k_t = 4G/(2 - \nu) \), where \( G \) is the shear modulus, related to Young’s modulus \( E \) by \( G = E/(2(1+\nu)) \), where \( \nu \) is Poisson’s ratio. This can also be achieved by specifying *NULL* for \( k_t \), in which case a normal contact model that specifies material parameters \( E \) and \( \nu \) is required (e.g. *hertz/material, dmt* or *jkr*). In this case, mixing of the shear modulus for different particle types \( i \) and \( j \) is done according to:

\[ 1/G = 2(2 - \nu_i)(1 + \nu_i)/E_i + 2(2 - \nu_j)(1 + \nu_j)/E_j \]

The *mindlin_rescale* option uses the same form as *mindlin*, but the magnitude of the tangential displacement is re-scaled as the contact unloads, i.e. if \( a < a_{t,n-1} \):

\[ \xi = \xi_{t,n-1} \frac{a}{a_{t,n-1}} \]
Here, $t_{n-1}$ indicates the value at the previous time step. This rescaling accounts for the fact that a decrease in the contact area upon unloading leads to the contact being unable to support the previous tangential loading, and spurious energy is created without the rescaling above (Walton). See also discussion in Thornton et al., 2013, particularly equation 18(b) of that work and associated discussion.

The optional rolling keyword enables rolling friction, which resists pure rolling motion of particles. The options currently supported are:

1. none
2. sds: $k_{roll}$, $\gamma_{roll}$, $\mu_{roll}$

If the rolling keyword is not specified, the model defaults to none.

For rolling sds, rolling friction is computed via a spring-dashpot-slider, using a ‘pseudo-force’ formulation, as detailed by Luding. Unlike the formulation in Marshall, this allows for the required adjustment of rolling displacement due to changes in the frame of reference of the contacting pair. The rolling pseudo-force is computed analogously to the tangential force:

$$F_{roll,0} = k_{roll}\xi_{roll} - \gamma_{roll} v_{roll}$$

Here, $v_{roll} = -R(\Omega_i - \Omega_j) \times n$ is the relative rolling velocity, as given in Wang et al and Luding. This differs from the expressions given by Kuhn and Bagi and used in Marshall; see Wang et al for details. The rolling displacement is given by:

$$\xi_{roll} = \int_{t_0}^{t} v_{roll}(\tau) d\tau$$

A Coulomb friction criterion truncates the rolling pseudo-force if it exceeds a critical value:

$$F_{roll} = \min(\mu_{roll} F_{n,0}, \|F_{roll,0}\|)k$$

Here, $k = v_{roll}/\|v_{roll}\|$ is the direction of the pseudo-force. As with tangential displacement, the rolling displacement is rescaled when the critical force is exceeded, so that the spring length corresponds the critical force. Additionally, the displacement is adjusted to account for rotations of the frame of reference of the two contacting particles in a manner analogous to the tangential displacement.

The rolling pseudo-force does not contribute to the total force on either particle (hence ‘pseudo’), but acts only to induce an equal and opposite torque on each particle, according to:

$$\tau_{roll,i} = R_{eff} n \times F_{roll}$$

$$\tau_{roll,j} = -\tau_{roll,i}$$

The optional twisting keyword enables twisting friction, which resists rotation of two contacting particles about the vector $n$ that connects their centers. The options currently supported are:

1. none
2. sds: $k_{twist}$, $\gamma_{twist}$, $\mu_{twist}$
3. marshall
If the `twisting` keyword is not specified, the model defaults to `none`.

For both `twisting sds` and `twisting marshall`, a history-dependent spring-dashpot-slider is used to compute the twisting torque. Because twisting displacement is a scalar, there is no need to adjust for changes in the frame of reference due to rotations of the particle pair. The formulation in Marshall therefore provides the most straightforward treatment:

\[ \tau_{\text{twist},0} = -k_{\text{twist}} \xi_{\text{twist}} - \gamma_{\text{twist}} \Omega_{\text{twist}} \]

Here \( \xi_{\text{twist}} = \int_{t_0}^{t} \Omega_{\text{twist}}(\tau) d\tau \) is the twisting angular displacement, and \( \Omega_{\text{twist}} = (\Omega_i - \Omega_j) \cdot n \) is the relative twisting angular velocity. The torque is then truncated according to:

\[ \tau_{\text{twist}} = \min(\mu_{\text{twist}} F_{n,0}, \tau_{\text{twist},0}) \]

Similar to the sliding and rolling displacement, the angular displacement is rescaled so that it corresponds to the critical value if the twisting torque exceeds this critical value:

\[ \xi_{\text{twist}} = \frac{1}{k_{\text{twist}}} (\mu_{\text{twist}} F_{n,0} \sgn(\Omega_{\text{twist}}) - \gamma_{\text{twist}} \Omega_{\text{twist}}) \]

For `twisting sds`, the coefficients \( k_{\text{twist}}, \gamma_{\text{twist}} \) and \( \mu_{\text{twist}} \) are simply the user input parameters that follow the `twisting sds` keywords in the `pair_coeff` command.

For `twisting marshall`, the coefficients are expressed in terms of sliding friction coefficients, as discussed in Marshall (see equations 32 and 33 of that work):

\[ k_{\text{twist}} = \frac{0.5 k t a^2}{2} \]
\[ \eta_{\text{twist}} = \frac{0.5 \eta t a^2}{3} \]
\[ \mu_{\text{twist}} = \frac{2}{3} \alpha \mu_t \]

Finally, the twisting torque on each particle is given by:

\[ \tau_{\text{twist},i} = \tau_{\text{twist}} n \]
\[ \tau_{\text{twist},j} = -\tau_{\text{twist},i} \]

The `granular` pair style can reproduce the behavior of the `pair gran/*` styles with the appropriate settings (some very minor differences can be expected due to corrections in displacement history frame-of-reference, and the application of the torque at the center of the contact rather than at each particle). The first example above is equivalent to `pair gran/hooke 1000.0 NULL 50.0 50.0 0.4 1`. The second example is equivalent to `pair gran/hooke/history 1000.0 500.0 50.0 50.0 0.4 1`. The third example is equivalent to `pair gran/hertz/history 1000.0 500.0 50.0 50.0 0.4 1`.

LAMMPS automatically sets pairwise cutoff values for `pair_style granular` based on particle radii (and in the case of `jkr` pull-off distances). In the vast majority of situations, this is adequate. However, a cutoff value can optionally be appended to the `pair_style granular` command to specify a global cutoff (i.e. a cutoff for all atom types). Additionally, the optional `cutoff` keyword can be passed to the `pair_coeff` command, followed by a cutoff value. This will set a pairwise cutoff for the atom types in the `pair_coeff` command. These options may be useful in some rare cases where the automatic cutoff determination is not sufficient, e.g. if particle diameters are being modified via the `fix adapt` command. In that case, the global cutoff specified as part of the `pair_style granular` command is applied to all atom types, unless it is overridden for a given atom type combination by the `cutoff` value specified in the `pair coeff` command. If `cutoff` is only specified in the `pair coeff` command and no global cutoff is appended to the `pair_style granular` command, then LAMMPS will use that cutoff for the specified atom type combination, and automatically set pairwise cutoffs for the remaining atom types.
Styles with a \texttt{gpu, intel, kk, omp, or opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

\textbf{Mixing, shift, table, tail correction, restart, rRESPA info:}

The \texttt{pair_modify} mix, shift, table, and tail options are not relevant for granular pair styles.

Mixing of coefficients is carried out using geometric averaging for most quantities, e.g. if friction coefficient for type 1-type 1 interactions is set to $\mu_1$, and friction coefficient for type 2-type 2 interactions is set to $\mu_2$, the friction coefficient for type 1-type2 interactions is computed as $\sqrt{\mu_1 \mu_2}$ (unless explicitly specified to a different value by a \texttt{pair_coeff} \texttt{1 2 ...} command). The exception to this is elastic modulus, only applicable to \texttt{hertz/material, dmt} and \texttt{jkr} normal contact models. In that case, the effective elastic modulus is computed as:

$$E_{eff,ij} = \left( \frac{1 - \nu_i^2}{E_i} + \frac{1 - \nu_j^2}{E_j} \right)^{-1}$$

If the $i$-$j$ coefficients $E_{ij}$ and $\nu_{ij}$ are explicitly specified, the effective modulus is computed as:

$$E_{eff,ij} = \left( \frac{1 - \nu_{ij}^2}{E_{ij}} + \frac{1 - \nu_{ij}^2}{E_{ij}} \right)^{-1}$$

or

$$E_{eff,ij} = \frac{E_{ij}}{2(1 - \nu_{ij})}$$

These pair styles write their information to \textit{binary restart files}, so a \texttt{pair_style} command does not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the \texttt{pair} keyword of the \texttt{run_style rRESPA} command. They do not support the \texttt{inner, middle, outer} keywords.

The single() function of these pair styles returns 0.0 for the energy of a pairwise interaction, since energy is not conserved in these dissipative potentials. It also returns only the normal component of the pairwise interaction force. However, the single() function also calculates 12 extra pairwise quantities. The first 3 are the components of the tangential force between particles I and J, acting on particle I. The fourth is the magnitude of this tangential force. The next 3 (5-7) are the components of the rolling torque acting on particle I. The next entry (8) is the magnitude of the rolling torque. The next entry (9) is the magnitude of the twisting torque acting about the vector connecting the two particle centers. The last 3 (10-12) are the components of the vector connecting the centers of the two particles ($x_{\text{I}} - x_{\text{J}}$).

These extra quantities can be accessed by the \texttt{compute pair/local} command, as $p1, p2, \ldots, p12$. 
18.224.4 Restrictions

All the granular pair styles are part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair styles require that atoms store torque and angular velocity (omega) as defined by the atom_style. They also require a per-particle radius is stored. The sphere atom style does all of this.

This pair style requires you to use the comm_modify vel yes command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the read_restart command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the read_restart command for more details.

```
18.231.3 Description

The \textit{lj/gromacs} styles compute shifted LJ and Coulombic interactions with an additional switching function \textit{S(r)} that ramps the energy and force smoothly to zero between an inner and outer cutoff. It is a commonly used potential in the GROMACS MD code and for the coarse-grained models of (Marrink).

\begin{align*}
E_{LJ} &= 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] + S_{LJ}(r) \quad r < r_c \\
E_C &= \frac{Cq_iq_j}{er} + S_C(r) \quad r < r_c \\
S(r) &= C \quad r < r_1 \\
S(r) &= \frac{A}{3}(r - r_1)^3 + \frac{B}{4}(r - r_1)^4 + C \quad r_1 < r < r_c \\
A &= (-3E'(r_c) + (r_c - r_1)E''(r_c))/(r_c - r_1)^2 \\
B &= (2E'(r_c) - (r_c - r_1)E''(r_c))/(r_c - r_1)^3 \\
C &= -E(r_c) + \frac{1}{2}(r_c - r_1)E'(r_c) - \frac{1}{12}(r_c - r_1)^2E''(r_c)
\end{align*}

\( r_1 \) is the inner cutoff; \( r_c \) is the outer cutoff. The coefficients A, B, and C are computed by LAMMPS to perform the shifting and smoothing. The function \textit{S(r)} is actually applied once to each term of the LJ formula and once to the Coulombic formula, so there are 2 or 3 sets of A,B,C coefficients depending on which \textit{pair_style} is used. The boundary conditions applied to the smoothing function are as follows: \( S'(r_1) = S''(r_1) = 0, S(r_c) = -E(r_c), S'(r_c) = -E'(r_c), \) and \( S''(r_c) = -E''(r_c) \), where \( E(r) \) is the corresponding term in the LJ or Coulombic potential energy function. Single and double primes denote first and second derivatives with respect to \( r \), respectively.

The inner and outer cutoff for the LJ and Coulombic terms can be the same or different depending on whether 2 or 4 arguments are used in the \textit{pair_style} command. The inner LJ cutoff must be > 0, but the inner Coulombic cutoff can be >= 0.

The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- inner (distance units)
- outer (distance units)

Note that sigma is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at \( 2^{1/6}\sigma \).

The last 2 coefficients are optional inner and outer cutoffs for style \textit{lj/gromacs}. If not specified, the global \textit{inner} and \textit{outer} values are used.

The last 2 coefficients cannot be used with style \textit{lj/gromacs/coul/gromacs} because this force field does not allow varying cutoffs for individual atom pairs; all pairs use the global cutoff(s) specified in the \textit{pair_style} command.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

None of the GROMACS pair styles support the pair_modify shift option, since the Lennard-Jones portion of the pair interaction is already smoothed to 0.0 at the cutoff.

The pair_modify table option is not relevant for this pair style.

None of the GROMACS pair styles support the pair_modify tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

All of the GROMACS pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

All of the GROMACS pair styles can only be used via the pair keyword of the run_style respa command. They do not support the `inner, middle, outer` keywords.

18.232 pair_style gw command

18.233 pair_style gw/zbl command

18.233.1 Syntax

pair_style style

  * style = gw or gw/zbl
18.233.2 Examples

```plaintext
pair_style gw
pair_coeff * * SiC.gw Si C C
pair_style gw/zbl
pair_coeff * * SiC.gw.zbl C Si
```

18.233.3 Description

The `gw` style computes a 3-body Gao-Weber potential; similarly `gw/zbl` combines this potential with a modified repulsive ZBL core function in a similar fashion as implemented in the `tersoff/zbl` pair style.

Unfortunately the author of this contributed code has not been able to submit a suitable documentation explaining the details of the potentials. The LAMMPS developers thus have finally decided to release the code anyway with only the technical explanations. For details of the model and the parameters, please refer to the linked publication.

Only a single `pair_coeff` command is used with the `gw` and `gw/zbl` styles which specifies a Gao-Weber potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of GW elements to atom types

See the `pair_coeff` doc page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.gw has Gao-Weber values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following `pair_coeff` command:

```plaintext
pair_coeff * * SiC.gw Si Si Si C
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the GW file. The final C argument maps LAMMPS atom type 4 to the C element in the GW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a `gw` potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Gao-Weber files in the `potentials` directory of the LAMMPS distribution have a “.gw” suffix. Gao-Weber with ZBL files have a “.gz.zbl” suffix. The structure of the potential files is similar to other many-body potentials supported by LAMMPS. You have to refer to the comments in the files and the literature to learn more details.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.
18.233.4 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The Gao-Weber potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the GW potential with any LAMMPS units, but you would need to create your own GW potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

pair_coeff 1 2 hbond/dreiding/morse 3 i 3.88 1.7241379 2.9 2 9 11 90
```

18.237.3 Description

The `hbond/dreiding` styles compute the Acceptor-Hydrogen-Donor (AHD) 3-body hydrogen bond interaction for the DREIDING force field, given by:

\[
E = \begin{cases} 
    L J(r) | M o r s e(r) | & r < r_{\text{in}} \\
    S(r) * [L J(r)|M o r s e(r)] & r_{\text{in}} < r < r_{\text{out}} \\
    0 & r > r_{\text{out}} 
\end{cases}
\]

where \( r_{\text{in}} \) is the inner spline distance cutoff, \( r_{\text{out}} \) is the outer distance cutoff, \( \theta_c \) is the angle cutoff, and \( n \) is the cosine periodicity.

Here, \( r \) is the radial distance between the donor (D) and acceptor (A) atoms and \( \theta \) is the bond angle between the acceptor, the hydrogen (H) and the donor atoms:

![Diagram](https://via.placeholder.com/150)

These 3-body interactions can be defined for pairs of acceptor and donor atoms, based on atom types. For each donor/acceptor atom pair, the third atom in the interaction is a hydrogen permanently bonded to the donor atom, e.g. in a bond list read in from a data file via the `read_data` command. The atom types of possible hydrogen atoms for each donor/acceptor type pair are specified by the `pair_coeff` command (see below).
Style `hbond/dreiding/lj` is the original DREIDING potential of (Mayo). It uses a LJ 12/10 functional for the Donor-Acceptor interactions. To match the results in the original paper, use \( n = 4 \).

Style `hbond/dreiding/morse` is an improved version using a Morse potential for the Donor-Acceptor interactions. (Liu) showed that the Morse form gives improved results for Dendrimer simulations, when \( n = 2 \).

See the `Howto bioFF` doc page for more information on the DREIDING force field.

**Note:** Because the Dreiding hydrogen bond potential is only one portion of an overall force field which typically includes other pairwise interactions, it is common to use it as a sub-style in a `pair_style hybrid/overlay` command, where another pair style provides the repulsive core interaction between pairs of atoms, e.g. a \( 1/r^12 \) Lennard-Jones repulsion.

**Note:** When using the `hbond/dreiding` pair styles with `pair_style hybrid/overlay`, you should explicitly define pair interactions between the donor atom and acceptor atoms, (as well as between these atoms and ALL other atoms in your system). Whenever `pair_style hybrid/overlay` is used, ordinary mixing rules are not applied to atoms like the donor and acceptor atoms because they are typically referenced in multiple pair styles. Neglecting to do this can cause difficult-to-detect physics problems.

**Note:** In the original Dreiding force field paper 1-4 non-bonded interactions ARE allowed. If this is desired for your model, use the special_bonds command (e.g. “special_bonds lj 0.0 0.0 1.0”) to turn these interactions on.

The following coefficients must be defined for pairs of eligible donor/acceptor types via the `pair_coeff` command as in the examples above.

**Note:** Unlike other pair styles and their associated `pair_coeff` commands, you do not need to specify `pair_coeff` settings for all possible I,J type pairs. Only I,J type pairs for atoms which act as joint donors/acceptors need to be specified; all other type pairs are assumed to be inactive.

**Note:** A `pair_coeff` command can be specified multiple times for the same donor/acceptor type pair. This enables multiple hydrogen types to be assigned to the same donor/acceptor type pair. For other pair_styles, if the `pair_coeff` command is re-used for the same IJ type pair, the settings for that type pair are overwritten. For the hydrogen bond potentials this is not the case; the settings are cumulative. This means the only way to turn off a previous setting, is to re-use the `pair_style` command and start over.

For the `hbond/dreiding/lj` style the list of coefficients is as follows:

- \( K = \) hydrogen atom type = 1 to Ntypes
- \( \text{donor flag} = i \) or \( j \)
- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- \( n = \) exponent in formula above
- distance cutoff \( r_{in} \) (distance units)
- distance cutoff \( r_{out} \) (distance units)
• angle cutoff (degrees)

For the hbond/dreiding/morse style the list of coefficients is as follows:

• \( K \) = hydrogen atom type = 1 to Ntypes
• donor flag = \( i \) or \( j \)
• \( D_0 \) (energy units)
• \( \alpha \) (1/distance units)
• \( r_0 \) (distance units)
• \( n \) = exponent in formula above
• distance cutoff \( r_{in} \) (distance units)
• distance cutoff \( r_{out} \) (distance units)
• angle cutoff (degrees)

A single hydrogen atom type \( K \) can be specified, or a wild-card asterisk can be used in place of or in conjunction with the \( K \) arguments to select multiple types as hydrogen atoms. This takes the form “\*” or “\#n” or “n\#” or “m*n”. See the pair_coeff command doc page for details.

If the donor flag is \( i \), then the atom of type I in the pair_coeff command is treated as the donor, and J is the acceptor. If the donor flag is \( j \), then the atom of type J in the pair_coeff command is treated as the donor and I is the donor. This option is required because the pair_coeff command requires that \( I \leq J \).

\( \epsilon \) and \( \sigma \) are settings for the hydrogen bond potential based on a Lennard-Jones functional form. Note that sigma is defined as the zero-crossing distance for the potential, not as the energy minimum at \( 2^{1/6}\sigma \).

\( D_0 \) and \( \alpha \) and \( r_0 \) are settings for the hydrogen bond potential based on a Morse functional form.

The last 3 coefficients for both styles are optional. If not specified, the global \( n \), distance cutoff, and angle cutoff specified in the pair_style command are used. If you wish to only override the second or third optional parameter, you must also specify the preceding optional parameters.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

These pair styles do not support mixing. You must explicitly identify each donor/acceptor type pair.

These styles do not support the pair_modify shift option for the energy of the interactions.

The pair_modify table option is not relevant for these pair styles.

These pair styles do not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.
These pair styles do not write their information to *binary restart files*, so *pair_style* and *pair_coeff* commands need to be re-specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run_style respa* command. They do not support the *inner, middle, outer* keywords.

These pair styles tally a count of how many hydrogen bonding interactions they calculate each timestep and the hbond energy. These quantities can be accessed via the *compute pair* command as a vector of values of length 2.

To print these quantities to the log file (with a descriptive column heading) the following commands could be included in an input script:

```bash
compute hb all pair hbond/dreiding/ij
variable n_hbond equal c_hb[1] #number hbonds
variable E_hbond equal c_hb[2] #hbond energy
thermo_style custom step temp epair v_E_hbond
```

pair_coeff * * lj/cut 1.0 1.0
pair_coeff * * coul/long
```

18.241.3 Description

The `hybrid` and `hybrid/overlay` styles enable the use of multiple pair styles in one simulation. With the `hybrid` style, exactly one pair style is assigned to each pair of atom types. With the `hybrid/overlay` style, one or more pair styles can be assigned to each pair of atom types. The assignment of pair styles to type pairs is made via the `pair_coeff` command.

Here are two examples of hybrid simulations. The `hybrid` style could be used for a simulation of a metal droplet on a LJ surface. The metal atoms interact with each other via an `eam` potential, the surface atoms interact with each other via a `lj/cut` potential, and the metal/surface interaction is also computed via a `lj/cut` potential. The `hybrid/overlay` style could be used as in the second example above, where multiple potentials are superposed in an additive fashion to compute the interaction between atoms. In this example, using `lj/cut` and `coul/long` together gives the same result as if the `lj/cut/coul/long` potential were used by itself. In this case, it would be more efficient to use the single combined potential, but in general any combination of pair potentials can be used together in to produce an interaction that is not encoded in any single pair_style file, e.g. adding Coulombic forces between granular particles.

All pair styles that will be used are listed as “sub-styles” following the `hybrid` or `hybrid/overlay` keyword, in any order. Each sub-style’s name is followed by its usual arguments, as illustrated in the example above. See the doc pages of individual pair styles for a listing and explanation of the appropriate arguments.

Note that an individual pair style can be used multiple times as a sub-style. For efficiency this should only be done if your model requires it. E.g. if you have different regions of Si and C atoms and wish to use a Tersoff potential for pure Si for one set of atoms, and a Tersoff potential for pure C for the other set (presumably with some third potential for Si-C interactions), then the sub-style `tersoff` could be listed twice. But if you just want to use a Lennard-Jones or other pairwise potential for several different atom type pairs in your model, then you should just list the sub-style once and use the `pair_coeff` command to assign parameters for the different type pairs.

Note: There is one exception to this option to list an individual pair style multiple times: GPU-enabled pair styles in the GPU package. This is because the GPU package currently assumes that only one instance of a pair style is being used.

In the `pair_coeff` commands, the name of a pair style must be added after the IJ type specification, with the remaining coefficients being those appropriate to that style. If the pair style is used multiple times in the `pair_style` command, then an additional numeric argument must also be specified which is a number from 1 to M where M is the number of times the sub-style was listed in the pair style command. The extra number indicates which instance of the sub-style these coefficients apply to.

For example, consider a simulation with 3 atom types: types 1 and 2 are Ni atoms, type 3 are LJ atoms with charges. The following commands would set up a hybrid simulation:

```plaintext
pair_style hybrid eam/alloy lj/cut/coul/cut 10.0 lj/cut 8.0
pair_coeff * * eam/alloy nialhjea Ni Ni NULL
(continues on next page)
```
As an example of using the same pair style multiple times, consider a simulation with 2 atom types. Type 1 is Si, type 2 is C. The following commands would model the Si atoms with Tersoff, the C atoms with Tersoff, and the cross-interactions with Lennard-Jones:

```
pair_style hybrid lj/cut 2.5 tersoff tersoff
pair_coeff * * tersoff 1 Si.tersoff Si NULL
pair_coeff * * tersoff 2 C.tersoff NULL C
pair_coeff 1 2 lj/cut 1.0 1.5
```

If pair coefficients are specified in the data file read via the `read_data` command, then the same rule applies. E.g. “eam/alloy” or “lj/cut” must be added after the atom type, for each line in the “Pair Coefs” section, e.g.

```
Pair Coeffs
1 lj/cut/coul/cut 1.0 1.0
...
```

Note that the `pair_coeff` command for some potentials such as `pair_style eam/alloy` includes a mapping specification of elements to all atom types, which in the hybrid case, can include atom types not assigned to the `eam/alloy` potential. The NULL keyword is used by many such potentials (eam/alloy, Tersoff, AIREBO, etc), to denote an atom type that will be assigned to a different sub-style.

For the `hybrid` style, each atom type pair I,J is assigned to exactly one sub-style. Just as with a simulation using a single pair style, if you specify the same atom type pair in a second `pair_coeff` command, the previous assignment will be overwritten.

For the `hybrid/overlay` style, each atom type pair I,J can be assigned to one or more sub-styles. If you specify the same atom type pair in a second `pair_coeff` command with a new sub-style, then the second sub-style is added to the list of potentials that will be calculated for two interacting atoms of those types. If you specify the same atom type pair in a second `pair_coeff` command with a sub-style that has already been defined for that pair of atoms, then the new pair coefficients simply override the previous ones, as in the normal usage of the `pair_coeff` command. E.g. these two sets of commands are the same:

```
pair_style lj/cut 2.5
pair_coeff * * 1.0 1.0
pair_coeff 2 2 1.5 0.8
pair_style hybrid/overlay lj/cut 2.5
pair_coeff * * lj/cut 1.0 1.0
pair_coeff 2 2 lj/cut 1.5 0.8
```

Coefficients must be defined for each pair of atom types via the `pair_coeff` command as described above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below.

For both the `hybrid` and `hybrid/overlay` styles, every atom type pair IJ (where I \(\leq\) J) must be assigned to at least one sub-style via the `pair_coeff` command as in the examples above, or in the data file read by the `read_data`, or by mixing as described below.

If you want there to be no interactions between a particular pair of atom types, you have 3 choices. You can assign the type pair to some sub-style and use the `neigh_modify exclude type` command. You can assign it to some sub-style and set the coefficients so that there is effectively no interaction (e.g. epsilon = 0.0 in a LJ potential). Or, for `hybrid` and `hybrid/overlay` simulations, you can use this form of the `pair_coeff` command in your input script:
or this form in the “Pair Coeffs” section of the data file:

3 none

If an assignment to none is made in a simulation with the hybrid/overlay pair style, it wipes out all previous assignments of that atom type pair to sub-styles.

Note that you may need to use an atom_style hybrid command in your input script, if atoms in the simulation will need attributes from several atom styles, due to using multiple pair potentials.

Different force fields (e.g. CHARMM vs AMBER) may have different rules for applying weightings that change the strength of pairwise interactions between pairs of atoms that are also 1-2, 1-3, and 1-4 neighbors in the molecular bond topology, as normally set by the special_bonds command. Different weights can be assigned to different pair hybrid sub-styles via the pair_modify special command. This allows multiple force fields to be used in a model of a hybrid system, however, there is no consistent approach to determine parameters automatically for the interactions between the two force fields, this is only recommended when particles described by the different force fields do not mix.

Here is an example for mixing CHARMM and AMBER: The global amber setting sets the 1-4 interactions to non-zero scaling factors and then overrides them with 0.0 only for CHARMM:

```plaintext
special_bonds amber
pair_hybrid lj/charmm/coul/long 8.0 10.0 lj/cut/coul/long 10.0
pair_modify pair lj/charmm/coul/long special lj/coul 0.0 0.0 0.0
```

The this input achieves the same effect:

```plaintext
special_bonds 0.0 0.0 0.1
pair_hybrid lj/charmm/coul/long 8.0 10.0 lj/cut/coul/long 10.0
pair_modify pair lj/cut/coul/long special lj 0.0 0.0 0.5
pair_modify pair lj/cut/coul/long special coul 0.0 0.0 0.83333333
pair_modify pair lj/charmm/coul/long special lj/coul 0.0 0.0 0.0
```

Here is an example for mixing Tersoff with OPLS/AA based on a data file that defines bonds for all atoms where for the Tersoff part of the system the force constants for the bonded interactions have been set to 0. Note the global settings are effectively lj/coul 0.0 0.0 0.5 as required for OPLS/AA:

```plaintext
special_bonds 1j/coul 1e-20 1e-20 0.5
pair_hybrid tersoff 1j/cut/coul/long 12.0
pair_modify pair tersoff special lj/coul 1.0 1.0 1.0
```

For use with the various compute */tally computes, the pair_modify compute/tally command can be used to selectively turn off processing of the compute tally styles, for example, if those pair styles (e.g. many-body styles) do not support this feature.

See the pair_modify doc page for details on the specific syntax, requirements and restrictions.

The potential energy contribution to the overall system due to an individual sub-style can be accessed and output via the compute pair command.
A subset of atom types is assigned to the many-body potential with a single `pair_coeff` command, using "* *" to include all types and the NULL keywords described above to exclude specific types not assigned to that potential. If types 1,3,4 were assigned in that way (but not type 2), this means that all many-body interactions between all atoms of types 1,3,4 will be computed by that potential. `Pair_style hybrid` allows interactions between type pairs 2-2, 1-2, 2-3, 2-4 to be specified for computation by other pair styles. You could even add a second interaction for 1-1 to be computed by another pair style, assuming `pair_style hybrid/overlay` is used.

But you should not, as a general rule, attempt to exclude the many-body interactions for some subset of the type pairs within the set of 1,3,4 interactions, e.g. exclude 1-1 or 1-3 interactions. That is not conceptually well-defined for many-body interactions, since the potential will typically calculate energies and forces for small groups of atoms, e.g. 3 or 4 atoms, using the neighbor lists of the atoms to find the additional atoms in the group. It is typically non-physical to think of excluding an interaction between a particular pair of atoms when the potential computes 3-body or 4-body interactions.

However, you can still use the `pair_coeff none` setting or the `neigh_modify exclude` command to exclude certain type pairs from the neighbor list that will be passed to a many-body sub-style. This will alter the calculations made by a many-body potential, since it builds its list of 3-body, 4-body, etc interactions from the pair list. You will need to think carefully as to whether it produces a physically meaningful result for your model.

For example, imagine you have two atom types in your model, type 1 for atoms in one surface, and type 2 for atoms in the other, and you wish to use a Tersoff potential to compute interactions within each surface, but not between surfaces. Then either of these two command sequences would implement that model:

```
pair_style hybrid tersoff
pair_coeff * * tersoff SiC.tersoff C C
pair_coeff 1 2 none

pair_style tersoff
pair_coeff * * SiC.tersoff C C
neigh_modify exclude type 1 2
```

Either way, only neighbor lists with 1-1 or 2-2 interactions would be passed to the Tersoff potential, which means it would compute no 3-body interactions containing both type 1 and 2 atoms.

Here is another example, using `hybrid/overlay`, to use 2 many-body potentials together, in an overlapping manner. Imagine you have CNT (C atoms) on a Si surface. You want to use Tersoff for Si/Si and Si/C interactions, and AIREBO for C/C interactions. Si atoms are type 1; C atoms are type 2. Something like this will work:

```
pair_style hybrid/overlay tersoff airebo 3.0
pair_coeff * * tersoff SiC.tersoff.custom Si C
pair_coeff * * airebo CH.airebo NULL C
```

Note that to prevent the Tersoff potential from computing C/C interactions, you would need to modify the SiC.tersoff file to turn off C/C interaction, i.e. by setting the appropriate coefficients to 0.0.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page.

Since the `hybrid` and `hybrid/overlay` styles delegate computation to the individual sub-styles, the suffix versions of the `hybrid` and `hybrid/overlay` styles are used to propagate the corresponding suffix to all sub-styles, if those versions exist. Otherwise the non-accelerated version will be used.
The individual accelerated sub-styles are part of the GPU, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

Any pair potential settings made via the pair_modify command are passed along to all sub-styles of the hybrid potential.

For atom type pairs I,J and I != J, if the sub-style assigned to I,I and J,J is the same, and if the sub-style allows for mixing, then the coefficients for I,J can be mixed. This means you do not have to specify a pair_coeff command for I,J since the I,J type pair will be assigned automatically to the sub-style defined for both I,I and J,J and its coefficients generated by the mixing rule used by that sub-style. For the hybrid/overlay style, there is an additional requirement that both the I,I and J,J pairs are assigned to a single sub-style. See the “pair_modify” command for details of mixing rules. See the doc page for the sub-style to see if allows for mixing.

The hybrid pair styles supports the pair_modify shift, table, and tail options for an I,J pair interaction, if the associated sub-style supports it.

For the hybrid pair styles, the list of sub-styles and their respective settings are written to binary restart files, so a pair_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file. Thus, pair_coeff commands need to be re-specified in the restart input script.

These pair styles support the use of the inner, middle, and outer keywords of the run_style respa command, if their sub-styles do.

18.241.4 Restrictions

When using a long-range Coulombic solver (via the kspace_style command) with a hybrid pair_style, one or more sub-styles will be of the “long” variety, e.g. lj/cut/coul/long or buck/coul/long. You must insure that the short-range Coulombic cutoff used by each of these long pair styles is the same or else LAMMPS will generate an error.

### 18.242.3 Description

The `ilp/graphene/hbn` style computes the registry-dependent interlayer potential (ILP) potential as described in (Leven1), (Leven2) and (Maaravi). The normals are calculated in the way as described in (Kolmogorov).

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}
\]

\[
V_{ij} = \text{Tap}(r_{ij}) \left\{ e^{-\alpha(r_{ij}/\beta-1)} \left[ \epsilon + f(\rho_{ij}) + f(\rho_{ji}) \right] - \frac{1}{1 + e^{-d(\epsilon(r_{ij}/sR\cdot r_{eff}))/\delta}} \right\} C_6 \rho_{ij}^6
\]

\[
\rho_{ij}^2 = r_{ij}^2 - (r_{ij} \cdot n_i)^2
\]

\[
\rho_{ji}^2 = r_{ij}^2 - (r_{ij} \cdot n_j)^2
\]

\[
f(\rho) = Ce^{-\rho/(\delta)^2}
\]

\[
\text{Tap}(r_{ij}) = 20 \left( \frac{r_{ij}}{R_{cut}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{cut}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{cut}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{cut}} \right)^4 + 1
\]

Where \( \text{Tap}(r_{ij}) \) is the taper function which provides a continuous cutoff (up to third derivative) for interatomic separations larger than \( r_c \) (Maaravi). The definitions of each parameter in the above equation can be found in (Leven1) and (Maaravi).

It is important to include all the pairs to build the neighbor list for calculating the normals.

**Note:** This potential (ILP) is intended for interlayer interactions between two different layers of graphene, hexagonal boron nitride (h-BN) and their hetero-junction. To perform a realistic simulation, this potential must be used in combination with intralayer potential, such as AIREBO or Tersoff potential. To keep the intralayer properties unaffected, the interlayer interaction within the same layers should be avoided. Hence, each atom has to have a layer identifier such that atoms residing on the same layer interact via the appropriate intralayer potential and atoms residing on different layers interact via the ILP. Here, the molecule id is chosen as the layer identifier, thus a data file with the “full” atom style is required to use this potential.

The parameter file (e.g. BNCH.ILP), is intended for use with *metal units*, with energies in meV. Two additional parameters, \( S \), and \( rcut \) are included in the parameter file. \( S \) is designed to facilitate scaling of energies. \( rcut \) is designed to build the neighbor list for calculating the normals for each atom pair.

**Note:** The parameters presented in the parameter file (e.g. BNCH.ILP), are fitted with taper function by setting the cutoff equal to 16.0 Angstrom. Using different cutoff or taper function should be careful. The parameters for atoms...
pairs between Boron and Nitrogen are fitted with a screened Coulomb interaction `coul/shield`. Therefore, to simulated the properties of h-BN correctly, this potential must be used in combination with the pair style `coul/shield`.

**Note:** Four new sets of parameters of ILP for 2D layered Materials with bilayer and bulk configurations are presented in *(Ouyang1)* and *(Ouyang2)*, respectively. These parameters provide a good description in both short- and long-range interaction regimes. While the old ILP parameters published in *(Leven2)* and *(Maaravi)* are only suitable for long-range interaction regime. This feature is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance). The benchmark tests and comparison of these parameters can be found in *(Ouyang1)* and *(Ouyang2)*.

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style `none`.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the `compute pair` command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1. $E_{\text{vdW}} = \text{vdW (attractive energy)}$
2. $E_{\text{Rep}} = \text{Repulsive energy}$

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```bash
compute 0 all pair ilp/graphene/hbn
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

### 18.242.4 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

This pair potential requires the newton setting to be *on* for pair interactions.

The BNCH.ILP potential file provided with LAMMPS (see the potentials directory) are parameterized for *metal* units. You can use this potential with any LAMMPS units, but you would need to create your BNCH.ILP potential file with coefficients listed in the appropriate units, if your simulation does not use *metal* units.

18.243 pair_style kim command

18.243.1 Syntax

```
pair_style kim model
```

model = name of a KIM model (the KIM ID for models archived in OpenKIM)

18.243.2 Examples

```
pair_style kim SW_StillingerWeber_1985_Si__MO_405512056662_005
pair_coeff * * Si
```

18.243.3 Description

This pair style is a wrapper on the Open Knowledgebase of Interatomic Models (OpenKIM) repository of interatomic potentials to enable their use in LAMMPS scripts.

The preferred interface for using interatomic models archived in OpenKIM is the `kim_commands interface`. That interface supports both “KIM Portable Models” (PMs) that conform to the KIM API Portable Model Interface (PMI) and can be used by any simulation code that conforms to the KIM API/PMI, and “KIM Simulator Models” that are natively implemented within a single simulation code (like LAMMPS) and can only be used with it. The `pair_style kim` command is limited to KIM PMs. It is used by the `kim_commands interface` as needed.

Note: Since `pair_style kim` is called by `kim_interactions` as needed, is not recommended to be directly used in input scripts.

The argument `model` is the name of the KIM PM. For potentials archived in OpenKIM this is the extended KIM ID (see `kim_commands` for details). LAMMPS can invoke any KIM PM, however there can be incompatibilities (for example...
due to unit matching issues). In the event of an incompatibility, the code will terminate with an error message. Check both the LAMMPS and KIM log files for details.

Only a single \textit{pair\_coeff} command is used with the \textit{kim} style, which specifies the mapping of LAMMPS atom types to the species supported by the KIM PM. This is done by specifying \textit{N} additional arguments after the * * in the \textit{pair\_coeff} command, where \textit{N} is the number of LAMMPS atom types:

- \textit{N} element names = mapping of KIM elements to atom types

For example, consider a KIM PM that supports Si and C species. If the LAMMPS simulation has four atom types, where the first three are Si, and the fourth is C, the following \textit{pair\_coeff} command would be used:

\begin{verbatim}
pair_coeff * * Si Si Si C
\end{verbatim}

The first two arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1, 2, and 3 to Si as defined within KIM PM. The final C argument maps LAMMPS atom type 4 to C.

In addition to the usual LAMMPS error messages, the KIM library itself may generate errors, which should be printed to the screen. In this case it is also useful to check the \textit{kim.log} file for additional error information. The file \textit{kim.log} should be generated in the same directory where LAMMPS is running.

To download, build, and install the KIM library on your system, see the \textit{lib/kim/README} file. Once you have done this and built LAMMPS with the KIM package installed you can run the example input scripts in \textit{examples/kim}.

Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support the \textit{pair\_modify} mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since KIM stores the potential parameters. Thus, you need to re-specify the \textit{pair\_style} and \textit{pair\_coeff} commands in an input script that reads a restart file.

This pair style can only be used via the \textit{pair} keyword of the \textit{run\_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

18.243.4 Restrictions

This pair style is part of the KIM package. See details on restrictions in \textit{kim\_commands}.

This current version of pair\_style kim is compatible with the kim-api package version 2.0.0 and higher.

18.243.5 Related commands

```

- `cutoff` = global cutoff (distance units)
- `tap_flag` = 0/1 to turn off/on the taper function

18.244.2 Examples

```plaintext
pair_style hybrid/overlay kolmogorov/crespi/full 20.0 0
pair_coeff * * none
pair_coeff * * kolmogorov/crespi/full CH.KC C C

pair_style hybrid/overlay rebo kolmogorov/crespi/full 16.0 1
pair_coeff * * rebo CH.rebo C H
pair_coeff * * kolmogorov/crespi/full CH_taper.KC C H
```

18.244.3 Description

The `kolmogorov/crespi/full` style computes the Kolmogorov-Crespi (KC) interaction potential as described in (Kolmogorov). No simplification is made,

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}
\]

\[
V_{ij} = e^{-\lambda(r_{ij} - z_0)} \left[ C + f(\rho_{ij}) + f(\rho_{ji}) - A \left( \frac{r_{ij}}{z_0} \right)^{-6} \right]
\]

\[
\rho_{ij}^2 = r_{ij}^2 - (r_{ij} \cdot n_i)^2
\]

\[
\rho_{ji}^2 = r_{ij}^2 - (r_{ij} \cdot n_j)^2
\]

\[
f(\rho) = e^{-\left(\rho/\delta\right)^2} \sum_{n=0}^{\infty} C_{2n}(\rho/\delta)^{2n}
\]

It is important to have a sufficiently large cutoff to ensure smooth forces and to include all the pairs to build the neighbor list for calculating the normals. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of \( V_{ij} \) (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for \( V_{ij} \) above. This is essential only when the taper function is turned off. The formula of taper function can be found in pair style `ilp/graphene/hbn`.

**Note:** This potential (ILP) is intended for interlayer interactions between two different layers of graphene. To perform a realistic simulation, this potential must be used in combination with intralayer potential, such as `AIREBO` or `Tersoff` potential. To keep the intralayer properties unaffected, the interlayer interaction within the same layers should be avoided. Hence, each atom has to have a layer identifier such that atoms residing on the same layer interact via the appropriate intralayer potential and atoms residing on different layers interact via the ILP. Here, the molecule id is chosen as the layer identifier, thus a data file with the “full” atom style is required to use this potential.
The parameter file (e.g. CH.KC), is intended for use with metal units, with energies in meV. Two additional parameters, $S$, and $rcut$ are included in the parameter file. $S$ is designed to facilitate scaling of energies. $rcut$ is designed to build the neighbor list for calculating the normals for each atom pair.

**Note:** Two new sets of parameters of KC potential for hydrocarbons, CH.KC (without the taper function) and CH_taper.KC (with the taper function) are presented in (Ouyang1). The energy for the KC potential with the taper function goes continuously to zero at the cutoff. The parameters in both CH.KC and CH_taper.KC provide a good description in both short- and long-range interaction regimes. While the original parameters (CC.KC) published in (Kolmogorov) are only suitable for long-range interaction regime. This feature is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance). The benchmark tests and comparison of these parameters can be found in (Ouyang1) and (Ouyang2).

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style none.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the `compute pair` command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1. $E_{vdW} = \text{vdW (attractive) energy}$
2. $E_{Rep} = \text{Repulsive energy}$

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```plaintext
compute 0 all pair kolmogorov/crespi/full
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

### 18.244.4 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair potential requires the newton setting to be on for pair interactions.

The CH.KC potential file provided with LAMMPS (see the potentials folder) are parameterized for metal units. You can use this potential with any LAMMPS units, but you would need to create your own custom CC.KC potential file with all coefficients converted to the appropriate units.

<td></td>
</tr>
<tr>
<td>pair_coeff 1 2 kolmogorov/crespi/z CC.KC C C</td>
<td></td>
</tr>
</tbody>
</table>

18.245.3 Description

The kolmogorov/crespi/z style computes the Kolmogorov-Crespi interaction potential as described in (Kolmogorov).

An important simplification is made, which is to take all normals along the z-axis.

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}
\]

\[
V_{ij} = e^{-\lambda (r_{ij} - z_0)} \left( C + f(\rho_{ij}) + f(\rho_{ji}) \right) - A \left( \frac{r_{ij}}{z_0} \right)^{-6} + A \left( \frac{\text{cutoff}}{z_0} \right)^{-6}
\]

\[
\rho_{ij}^2 = x_{ij}^2 + y_{ij}^2 \quad (n_i \equiv \hat{z})
\]

\[
f(\rho) = e^{-\left(\rho/\delta\right)^2} \sum_{n=0}^{2} C_{2n} \left( \rho/\delta \right)^{2n}
\]

It is important to have a sufficiently large cutoff to ensure smooth forces. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of \( V_{ij} \) (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for \( V_{ij} \) above.

This potential is intended for interactions between two layers of graphene. Therefore, to avoid interaction between layers in multi-layered materials, each layer should have a separate atom type and interactions should only be computed between atom types of neighboring layers.
The parameter file (e.g. CC.KC), is intended for use with metal units, with energies in meV. An additional parameter, $S$, is available to facilitate scaling of energies in accordance with (vanWijk). This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style none.

### 18.246 pair_style lcbop command

#### 18.246.1 Syntax

```
pair_style lcbop
```

#### 18.246.2 Examples

```
pair_style lcbop
pair_coeff * * ../potentials/C.lcbop C
```

#### 18.246.3 Description

The lcbop pair style computes the long-range bond-order potential for carbon (LCBOP) of (Los and Fasolino). See section II in that paper for the analytic equations associated with the potential.

Only a single pair_coeff command is used with the lcbop style which specifies an LCBOP potential file with parameters for specific elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of LCBOP elements to atom types
See the *pair_coeff* doc page for alternate ways to specify the path for the potential file.

As an example, if your LAMMPS simulation has 4 atom types and you want the first 3 to be C you would use the following *pair_coeff* command:

```
pair_coeff * * C.lcbop C C C NULL
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first C argument maps LAMMPS atom type 1 to the C element in the LCBOP file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *lcbop* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The parameters/coefficients for the LCBOP potential as applied to C are listed in the C.lcbop file to agree with the original (Los and Fasolino) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done carefully.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support the *pair_modify* mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the *pair_style* and *pair_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner, middle, outer* keywords.

### 18.246.4 Restrictions

This pair styles is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

This pair potential requires the *newton* setting to be “on” for pair interactions.

The C.lcbop potential file provided with LAMMPS (see the potentials directory) is parameterized for metal *units*. You can use the LCBOP potential with any LAMMPS units, but you would need to create your own LCBOP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

### 18.246.5 Related commands

*pair_airebo, pair_coeff*

```

18.247.2 Examples

```
pair_style hybrid/overlay lebedeva/z 20.0
pair_coeff * * none
pair_coeff 1 2 lebedeva/z CC.Lebedeva C C

pair_style hybrid/overlay rebo lebedeva/z 14.0
pair_coeff * * rebo CH.rebo C C
pair_coeff 1 2 lebedeva/z CC.Lebedeva C C
```

18.247.3 Description

The `lebedeva/z` style computes the Lebedeva interaction potential as described in (Lebedeva et al.). An important simplification is made, which is to take all normals along the z-axis.

\[
E = \frac{1}{2} \sum_i \sum_{i \neq j} V_{ij}
\]

\[
V_{ij} = Be^{-\alpha (r_{ij} - z_0)}
\]

\[
+ C(1 + D_1 \rho_{ij}^2 + D_2 \rho_{ij}^4 e^{-\lambda_1 \rho_{ij}^2} e^{-\lambda_2 (z_{ij}^2 - z_0^2)})
\]

\[
- A \left( \frac{z_0}{r_{ij}} \right)^6 + A \left( \frac{z_0}{r_c} \right)^6
\]

\[
\rho_{ij}^2 = x_{ij}^2 + y_{ij}^2 \quad (\mathbf{n}_i \equiv \hat{z})
\]

It is important to have a sufficiently large cutoff to ensure smooth forces. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of \(V_{ij}\) (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for \(V_{ij}\) above.

The parameter file (e.g. CC.Lebedeva), is intended for use with metal units, with energies in meV. An additional parameter, \(S\), is available to facilitate scaling of energies.

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style none.

18.247.4 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.248 pair_style line/lj command

18.248.1 Syntax

```
pair_style line/lj cutoff
```

cutoff = global cutoff for interactions (distance units)

18.248.2 Examples

```
pair_style line/lj 3.0
pair_coeff * * 1.0 1.0 0.8 1.12
pair_coeff 1 2 1.0 2.0 1.0 1.5 1.12 5.0
pair_coeff 1 2 1.0 2.0 1.0 2.5
```

18.248.3 Description

Style line/lj treats particles which are line segments as a set of small spherical particles that tile the line segment length as explained below. Interactions between two line segments, each with N1 and N2 spherical particles, are calculated as the pairwise sum of N1*N2 Lennard-Jones interactions. Interactions between a line segment with N spherical particles and a point particle are treated as the pairwise sum of N Lennard-Jones interactions. See the pair_style lj/cut doc page for the definition of Lennard-Jones interactions.

The set of non-overlapping spherical sub-particles that represent a line segment are generated in the following manner. Their size is a function of the line segment length and the specified sub-particle size for that particle type. If a line segment has a length L and is of type I, then the number of spheres N that represent the segment is calculated as N = L/sizeI, rounded up to an integer value. Thus if L is not evenly divisible by sizeI, N is incremented to include one extra sphere. The centers of the spheres are spaced equally along the line segment. Imagine N+1 equally-space points, which include the 2 end points of the segment. The sphere centers are halfway between each pair of points.

The LJ interaction between 2 spheres on different line segments (or a sphere on a line segment and a point particles) is computed with sub-particle \( \epsilon \), \( \sigma \), and cutoff values that are set by the pair_coeff command, as described below. If the distance between the 2 spheres is greater than the sub-particle cutoff, there is no interaction. This means that some pairs of sub-particles on 2 line segments may interact, but others may not.

For purposes of creating the neighbor list for pairs of interacting line segments or lines/point particles, a regular particle-particle cutoff is used, as defined by the cutoff setting above in the pair_style command or overridden with an optional argument in the pair_coeff command for a type pair as discussed below. The distance between the centers of 2 line segments, or the center of a line segment and a point particle, must be less than this distance (plus the neighbor skin; see the neighbor command), for the pair of particles to be included in the neighbor list.
Note: This means that a too-short value for the "cutoff" setting can exclude a pair of particles from the neighbor list even if pairs of their sub-particle spheres would interact, based on the sub-particle cutoff specified in the pair_coeff command. E.g. sub-particles at the ends of the line segments that are close to each other. Which may not be what you want, since it means the ends of 2 line segments could pass through each other. It is up to you to specify a "cutoff" setting that is consistent with the length of the line segments you are using and the sub-particle cutoff settings.

For style line/lj, the following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- sizeI (distance units)
- sizeJ (distance units)
- ε (energy units)
- σ (distance units)
- subcutoff (distance units)
- cutoff (distance units)

The sizeI and sizeJ coefficients are the sub-particle sizes for line particles of type I and type J. They are used to define the N sub-particles per segment as described above. These coefficients are actually stored on a per-type basis. Thus if there are multiple pair_coeff commands that involve type I, as either the first or second atom type, you should use consistent values for sizeI or sizeJ in all of them. If you do not do this, the last value specified for sizeI will apply to all segments of type I. If typel or typeJ refers to point particles, the corresponding sizeI or sizeJ is ignored; it can be set to 0.0.

The ε, σ, and subcutoff coefficients are used to compute an LJ interactions between a pair of sub-particles on 2 line segments (of type I and J), or between a sub particle/point particle pair. As discussed above, the subcutoff and cutoff params are different. The latter is only used for building the neighbor list when the distance between centers of two line segments or one segment and a point particle is calculated.

The cutoff coefficient is optional. If not specified, the global cutoff is used.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, coefficients must be specified. No default mixing rules are used.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.248.4 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Defining particles to be line segments so they participate in line/line or line/particle interactions requires the use the atom_style line command.
18.248.5 Related commands

pair_coeff, pair_style tri/lj

Default: none

18.249 pair_style list command

18.249.1 Syntax

\[
\text{pair_style list listfile cutoff keyword}
\]

- listfile = name of file with list of pairwise interactions
- cutoff = global cutoff (distance units)
- keyword = optional flag nocheck or check (default is check)

18.249.2 Examples

\[
\begin{align*}
\text{pair_style list restraints.txt 200.0} \\
\text{pair_coeff \ast \ast} \\
\text{pair_style hybrid/overlay lj/cut 1.1225 list pair_list.txt 300.0} \\
\text{pair_coeff \ast \ast lj/cut 1.0 1.0} \\
\text{pair_coeff 3* 3* list}
\end{align*}
\]

18.249.3 Description

Style list computes interactions between explicitly listed pairs of atoms with the option to select functional form and parameters for each individual pair. Because the parameters are set in the list file, the pair_coeff command has no parameters (but still needs to be provided). The check and nocheck keywords enable/disable a test that checks whether all listed bonds were present and computed.

This pair style can be thought of as a hybrid between bonded, non-bonded, and restraint interactions. It will typically be used as an additional interaction within the hybrid/overlay pair style. It currently supports three interaction styles: a 12-6 Lennard-Jones, a Morse and a harmonic potential.

The format of the list file is as follows:

- one line per pair of atoms
- empty lines will be ignored
- comment text starts with a ‘#’ character
- line syntax: ID1 ID2 style coeffs cutoff

<table>
<thead>
<tr>
<th>ID1</th>
<th>ID2</th>
<th>style</th>
<th>coeffs</th>
<th>cutoff</th>
</tr>
</thead>
<tbody>
<tr>
<td>atom ID of first atom</td>
<td>atom ID of second atom</td>
<td>style of interaction</td>
<td>list of coeffs</td>
<td>cutoff for interaction (optional)</td>
</tr>
</tbody>
</table>
The cutoff parameter is optional. If not specified, the global cutoff is used.

Here is an example file:

```plaintext
# this is a comment
15 259 lj126 1.0 1.0 50.0
15 603 morse 10.0 1.2 2.0 10.0 # and another comment
18 470 harmonic 50.0 1.2 5.0
```

The style *lj126* computes pairwise interactions with the formula

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \quad r < r_c \]

and the coefficients:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)

The style *morse* computes pairwise interactions with the formula

\[ E = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c \]

and the coefficients:

- \( D_0 \) (energy units)
- \( \alpha \) (1/distance units)
- \( r_0 \) (distance units)

The style *harmonic* computes pairwise interactions with the formula

\[ E = K(r - r_0)^2 \]

and the coefficients:

- \( K \) (energy units)
- \( r_0 \) (distance units)

Note that the usual 1/2 factor is included in \( K \).

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support mixing since all parameters are explicit for each pair.

The `pair_modify` shift option is supported by this pair style.

The `pair_modify` table and tail options are not relevant for this pair style.

This pair style does not write its information to binary restart files, so pair_style and pair_coeff commands need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.
18.249.4 Restrictions

This pair style does not use a neighbor list and instead identifies atoms by their IDs. This has two consequences: 1) The cutoff has to be chosen sufficiently large, so that the second atom of a pair has to be a ghost atom on the same node on which the first atom is local; otherwise the interaction will be skipped. You can use the check option to detect, if interactions are missing. 2) Unlike other pair styles in LAMMPS, an atom I will not interact with multiple images of atom J (assuming the images are within the cutoff distance), but only with the nearest image.

This style is part of the USER-MISC package. It is only enabled if LAMMPS is build with that package. See the Build package doc page on for more info.

### 18.284.3 Description

The `lj/cut` styles compute the standard 12/6 Lennard-Jones potential, given by

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c \]

\( r_c \) is the cutoff.

Style `lj/cut/coul/cut` adds a Coulombic pairwise interaction given by

\[ E = \frac{Cq_i q_j}{\epsilon r} \quad r < r_c \]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, and \( \epsilon \) is the dielectric constant which can be set by the `dielectric` command. If one cutoff is specified in the pair_style command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

Style `lj/cut/coul/debye` adds an additional \( \exp() \) damping factor to the Coulombic term, given by

\[ E = \frac{Cq_i q_j}{\epsilon r} \exp(-\kappa r) \quad r < r_c \]
where $\kappa$ is the inverse of the Debye length. This potential is another way to mimic the screening effect of a polar solvent.

Style $lj/cut/coul/dsf$ computes the Coulombic term via the damped shifted force model described in Fennell, given by:

$$E = q_i q_j \left[ \frac{\text{erfc}(\alpha r)}{r} - \frac{\text{erfc}(\alpha r_c)}{r_c} \right] + \frac{2\alpha \exp(-\alpha^2 r_c^2)}{\sqrt{\pi} r_c} \left( r - r_c \right) \quad r < r_c$$

where $\alpha$ is the damping parameter and erfc() is the complementary error-function. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise $1/r$ summation. The potential is based on Wolf summation, proposed as an alternative to Ewald summation for condensed phase systems where charge screening causes electrostatic interactions to become effectively short-ranged. In order for the electrostatic sum to be absolutely convergent, charge neutralization within the cutoff radius is enforced by shifting the potential through placement of image charges on the cutoff sphere. Convergence can often be improved by setting $\alpha$ to a small non-zero value.

Styles $lj/cut/coul/long$ and $lj/cut/coul/msm$ compute the same Coulombic interactions as style $lj/cut/coul/cut$ except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the $kspace_style$ command and its $ewald$ or $pppm$ option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

Style $coul/wolf$ adds a Coulombic pairwise interaction via the Wolf summation method, described in Wolf, given by:

$$E_i = \frac{1}{2} \sum_{j \neq i} q_i q_j \text{erfc}(\alpha r_{ij}) \frac{1}{r_{ij}} + \frac{1}{2} \sum_{j \neq i} q_i q_j \text{erfc}(\alpha r_{ij}) \frac{1}{r_{ij}} \quad r < r_c$$

where $\alpha$ is the damping parameter, and erfc() is the complementary error-function terms. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise $1/r$ summation. With a small enough damping parameter, the second term shrinks and the potential becomes a rapidly-converging real-space summation. With a long enough cutoff and small enough $\alpha$ parameter, the energy and forces calculated by the Wolf summation method approach those of the Ewald sum. So it is a means of getting effective long-range interactions with a short-range potential.

Styles $lj/cut/tip4p/cut$ and $lj/cut/tip4p/long$ implement the TIP4P water model of (Jorgensen), which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as $pair_style$ arguments. Style $lj/cut/tip4p/cut$ uses a cutoff for Coulomb interactions; style $lj/cut/tip4p/long$ is for use with a long-range Coulombic solver (Ewald or PPPM).

**Note:** For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

See the Howto tip4p doc page for more information on how to use the TIP4P pair styles and lists of parameters to set. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance $2qdist$ when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff $\geq$ Coulombic cutoff + $2qdist$, to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

For all of the $lj/cut$ pair styles, the following coefficients must be defined for each pair of atom types via the $pair_coeff$ command as in the examples above, or in the data file or restart files read by the $read_data$ or $read_restart$ commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
• cutoff1 (distance units)
• cutoff2 (distance units)

Note that $\sigma$ is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at $\frac{1}{\sqrt{2}} \sigma$.

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style $lj/cut$, since it has no Coulombic terms.

For $lj/cut/coul/long$ and $lj/cut/coul/msm$ and $lj/cut/tip4p/cut$ and $lj/cut/tip4p/long$ only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual IJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

A version of these styles with a soft core, $lj/cut/soft$, suitable for use in free energy calculations, is part of the USER-FEP package and is documented with the pair_style */soft styles. The version with soft core is only available if LAMMPS was built with that package. See the Build package doc page for more info.

Styles with a $gpu$, $intel$, $kk$, $omp$, or $opt$ suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the $-suffix$ command-line switch when you invoke LAMMPS, or you can use the $suffix$ command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I != J, the epsilon and sigma coefficients and cutoff distance for all of the $lj/cut$ pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

All of the $lj/cut$ pair styles support the $pair_modify$ shift option for the energy of the Lennard-Jones portion of the pair interaction.

The $lj/cut/coul/long$ and $lj/cut/tip4p/long$ pair styles support the $pair_modify$ table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the $lj/cut$ pair styles support the $pair_modify$ tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

All of the $lj/cut$ pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The $lj/cut$ and $lj/cut/coul/long$ pair styles support the use of the $inner$, $middle$, and $outer$ keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the $pair$ keyword of run_style respa. See the run_style command for details.
18.284.4 Restrictions

The \textit{lj/cut/coul/long} and \textit{lj/cut/tip4p/long} styles are part of the KSPACE package. The \textit{lj/cut/tip4p/cut} style is part of the MOLECULE package. These styles are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

18.287.1 Syntax

\begin{verbatim}
pair_style lj96/cut cutoff

\end{verbatim}

- \texttt{cutoff} = global cutoff for \textit{lj96/cut} interactions (distance units)

18.287.2 Examples

\begin{verbatim}
pair_style lj96/cut 2.5
pair_coeff * * 1.0 1.0 4.0
pair_coeff 1 1 1.0 1.0

\end{verbatim}

18.287.3 Description

The \textit{lj96/cut} style compute a 9/6 Lennard-Jones potential, instead of the standard 12/6 potential, given by

\[ E = 4\epsilon \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^6 \] \quad r < r_c

\( r_c \) is the cutoff.

The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands, or by mixing as described below:

- \( \epsilon \) (energy units)
• \( \sigma \) (distance units)
• cutoff (distance units)

The last coefficient is optional. If not specified, the global LJ cutoff specified in the pair_style command is used.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I \(!= J\), the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

This pair style supports the pair_modify shift option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the run_style command for details.

18.287.4 Restrictions

none

18.287.5 Related commands

pair_coeff

18.290.1 Syntax

```
pair_style lj/cubic
```

18.290.2 Examples

```
pair_style lj/cubic
pair_coeff * * 1.0 0.8908987
```

18.290.3 Description

The `lj/cubic` style computes a truncated LJ interaction potential whose energy and force are continuous everywhere. Inside the inflection point the interaction is identical to the standard 12/6 Lennard-Jones potential. The LJ function outside the inflection point is replaced with a cubic function of distance. The energy, force, and second derivative are continuous at the inflection point. The cubic coefficient $A_3$ is chosen so that both energy and force go to zero at the cutoff distance. Outside the cutoff distance the energy and force are zero.

$$
E = u_{LJ}(r) \quad r \leq r_s
$$
$$
= u_{LJ}(r_s) + (r - r_s)u'_{LJ}(r_s) - \frac{1}{6}A_3(r - r_s)^3 \quad r_s < r \leq r_c
$$
$$
= 0 \quad r > r_c
$$

The location of the inflection point $r_s$ is defined by the LJ diameter, $r_s/\sigma = (26/7)^{1/6}$. The cutoff distance is defined by $r_c/r_s = 67/48$ or $r_c/\sigma = 1.737...$. The analytic expression for the the cubic coefficient $A_3r_{min}^3/\epsilon = 27.93...$ is given in the paper by Holian and Ravelo (Holian).

This potential is commonly used to study the shock mechanics of FCC solids, as in Ravelo et al. (Ravelo).

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)

Note that $\sigma$ is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum, which is located at $r_{min} = 2^{1/6}\sigma$. In the above example, $\sigma = 0.8908987$, so $r_{min} = 1.0$.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

The lj/cubic pair style does not support the pair_modify shift option, since pair interaction is already smoothed to 0.0 at the cutoff.

The pair_modify table option is not relevant for this pair style.

The lj/cubic pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

The lj/cubic pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/cubic pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.290.4 Restrictions

18.294 pair_style lj/expand/omp command

18.295 pair_style lj/expand/coul/long command

18.296 pair_style lj/expand/coul/long/gpu command

18.296.1 Syntax

```
pair_style lj/expand cutoff
```

- cutoff = global cutoff for lj/expand interactions (distance units)

18.296.2 Examples

```
pair_style lj/expand 2.5
pair_coeff * * 1.0 1.0 0.5
pair_coeff 1 1 1.0 1.0 -0.2 2.0

pair_style lj/expand/coul/long 2.5
pair_style lj/expand/coul/long 2.5 4.0
pair_coeff * * 1.0 1.0 0.5
pair_coeff 1 1 1.0 1.0 -0.2 3.0
```

18.296.3 Description

Style lj/expand computes a LJ interaction with a distance shifted by delta which can be useful when particles are of different sizes, since it is different that using different sigma values in a standard LJ formula:

\[
E = 4\epsilon \left[ \left( \frac{\sigma}{r - \Delta} \right)^{12} - \left( \frac{\sigma}{r - \Delta} \right)^{6} \right] \quad r < r_c + \Delta
\]

\(r_c\) is the cutoff which does not include the \(\Delta\) distance. I.e. the actual force cutoff is the sum of \(r_c + \Delta\).

For all of the lj/expand pair styles, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- \(\epsilon\) (energy units)
- \(\sigma\) (distance units)
- \(\Delta\) (distance units)
- cutoff (distance units)

The $\Delta$ values can be positive or negative. The last coefficient is optional. If not specified, the global LJ cutoff is used.

For lj/expand/coul/long only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

For atom type pairs I,J and I ≠ J, the epsilon, sigma, and shift coefficients and cutoff distance for this pair style can be mixed. Shift is always mixed via an arithmetic rule. The other coefficients are mixed according to the pair_modify mix value. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style supports the pair_modify tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

```

18.302.3 Description

Style `lj/long/coul/long` computes the standard 12/6 Lennard-Jones potential:

\[ E = 4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \quad r < r_c \]

with \( \epsilon \) and \( \sigma \) being the usual Lennard-Jones potential parameters, plus the Coulomb potential, given by:

\[ E = \frac{C q_i q_j}{er} \quad r < r_c \]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, \( \epsilon \) is the dielectric constant which can be set by the `dielectric` command, and \( r_c \) is the cutoff. If one cutoff is specified in the pair_style command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

The purpose of this pair style is to capture long-range interactions resulting from both attractive 1/r^6 Lennard-Jones and Coulombic 1/r interactions. This is done by use of the `flag_lj` and `flag_coul` settings. The In ’t Veld paper has more details on when it is appropriate to include long-range 1/r^6 interactions, using this potential.

Style `lj/long/tip4p/long` implements the TIP4P water model of (Jorgensen), which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as pair_style arguments.

**Note:** For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

See the Howto tip4p doc page for more information on how to use the TIP4P pair style. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance 2*qdist when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff >= Coulombic cutoff + 2*qdist, to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

If `flag_lj` is set to `long`, no cutoff is used on the LJ 1/r^6 dispersion term. The long-range portion can be calculated by using the `kspace_style ewald/disp` or `pppm/disp` commands. The specified LJ cutoff then determines which portion of the LJ interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the KSpace style. If `flag_lj` is set to `cut`, the LJ interactions are simply cutoff, as with `pair_style lj/cut`.

If `flag_coul` is set to `long`, no cutoff is used on the Coulombic interactions. The long-range portion can be calculated by using any of several `kspace_style` command options such as `pppm` or `ewald`. Note that if `flag_lj` is also set to long, then
the ewald/disp or ppm/disp Kspace style needs to be used to perform the long-range calculations for both the LJ and Coulombic interactions. If flag_coul is set to off, Coulombic interactions are not computed.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

Note that sigma is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at $2^{1/6}$ sigma.

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

Note that if you are using flag_lj set to long, you cannot specify a LJ cutoff for an atom type pair, since only one global LJ cutoff is allowed. Similarly, if you are using flag_coul set to long, you cannot specify a Coulombic cutoff for an atom type pair, since only one global Coulombic cutoff is allowed.

For lj/long/tip4p/long only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

A version of these styles with a soft core, lj/cut/soft, suitable for use in free energy calculations, is part of the USER-FEP package and is documented with the pair_style */soft styles. The version with soft core is only available if LAMMPS was built with that package. See the Build package doc page for more info.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/long pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

These pair styles support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction, assuming flag_lj is cut.

These pair styles support the pair_modify table and table/disp options since they can tabulate the short-range portion of the long-range Coulombic and dispersion interactions.

These pair styles do not support the pair_modify tail option for adding a long-range tail correction to the Lennard-Jones portion of the energy and pressure.
These pair styles write their information to *binary restart files*, so *pair_style* and *pair_coeff* commands do not need to be specified in an input script that reads a restart file.

The pair lj/long/coul/long styles support the use of the *inner*, *middle*, and *outer* keywords of the *run_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the *run_style* command for details.

### 18.302.4 Restrictions

These styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

### 18.302.5 Related commands

*pair_coeff*

**Default:** none

### 18.303 pair_style lj/smooth command

### 18.304 pair_style lj/smooth/omp command

#### 18.304.1 Syntax

```
pair_style lj/smooth Rin Rc
```

- Rin = inner cutoff beyond which force smoothing will be applied (distance units)
- Rc = outer cutoff for lj/smooth interactions (distance units)

#### 18.304.2 Examples

```
pair_style lj/smooth 8.0 10.0
pair_coeff * * 10.0 1.5
pair_coeff 1 1 20.0 1.3 7.0 9.0
```
18.304.3 Description

Style *lj/smooth* computes a LJ interaction with a force smoothing applied between the inner and outer cutoff.

\[ E = 4\epsilon \left( \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right) \quad r < r_{in} \]
\[ F = C_1 + C_2(r - r_{in}) + C_3(r - r_{in})^2 + C_4(r - r_{in})^3 \quad r_{in} < r < r_c \]

The polynomial coefficients C1, C2, C3, C4 are computed by LAMMPS to cause the force to vary smoothly from the inner cutoff \( r_{in} \) to the outer cutoff \( r_c \).

At the inner cutoff the force and its first derivative will match the non-smoothed LJ formula. At the outer cutoff the force and its first derivative will be 0.0. The inner cutoff cannot be 0.0.

**Note:** this force smoothing causes the energy to be discontinuous both in its values and first derivative. This can lead to poor energy conservation and may require the use of a thermostat. Plot the energy and force resulting from this formula via the *pair_write* command to see the effect.

The following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- \( r_{in} \) (distance units)
- \( r_c \) (distance units)

The last 2 coefficients are optional inner and outer cutoffs. If not specified, the global values for \( r_{in} \) and \( r_c \) are used.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* command-line switch when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

For atom type pairs I,J and I \(!= J\), the epsilon, sigma, Rin coefficients and the cutoff distance for this pair style can be mixed. Rin is a cutoff value and is mixed like the cutoff. The other coefficients are mixed according to the *pair_modify* mix option. The default mix value is *geometric*. See the “pair_modify” command for details.

This pair style supports the *pair_modify* shift option for the energy of the pair interaction.

The *pair_modify* table option is not relevant for this pair style.

This pair style does not support the *pair_modify* tail option for adding long-range tail corrections to energy and pressure, since the energy of the pair interaction is smoothed to 0.0 at the cutoff.
This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

pair_style lj/smooth/linear cutoff
```

- cutoff = global cutoff for Lennard-Jones interactions (distance units)

18.306.2 Examples

```plaintext
pair_style lj/smooth/linear 2.5
pair_coeff * * 1.0 1.0
pair_coeff 1 1 0.3 3.0 9.0
```

18.306.3 Description

Style lj/smooth/linear computes a truncated and force-shifted LJ interaction (aka Shifted Force Lennard-Jones) that combines the standard 12/6 Lennard-Jones function and subtracts a linear term based on the cutoff distance, so that both, the potential and the force, go continuously to zero at the cutoff Rc (Toxvaerd):

\[
\phi (r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right]
\]

\[
E (r) = \phi (r) - \phi (R_c) - \left( r - R_c \right) \frac{d\phi}{dr} \bigg|_{r=R_c}
\]

r < Rc

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:
• $\epsilon$ (energy units)
• $\sigma$ (distance units)
• cutoff (distance units)

The last coefficient is optional. If not specified, the global LJ cutoff specified in the pair_style command is used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I ≠ J, the epsilon and sigma coefficients and cutoff distance can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the `pair_modify` shift option for the energy of the pair interaction, since it goes to 0.0 at the cutoff by construction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure, since the energy of the pair interaction is smoothed to 0.0 at the cutoff.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

`pair_coeff`, `pair lj/smooth`

Default: none

18.307  pair_style lj/switch3/coulgauss/long command

18.307.1 Syntax

```
pair_style style args
```

- style = lj/switch3/coulgauss/long
- args = list of arguments for a particular style

```
lj/switch3/coulgauss/long args = cutoff (cutoff2) width
  cutoff = global cutoff for LJ (and Coulombic if only 1 arg) (distance units)
  cutoff2 = global cutoff for Coulombic (optional) (distance units)
  width = width parameter of the smoothing function (distance units)
```

18.307.2 Examples

```
pair_style lj/switch3/coulgauss/long 12.0 3.0
pair_coeff 1 0.2 2.5 1.2
pair_style lj/switch3/coulgauss/long 12.0 10.0 3.0
pair_coeff 1 0.2 2.5 1.2
```

18.307.3 Description

The **lj/switch3/coulgauss** style evaluates the LJ vdW potential

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \]

which goes smoothly to zero at the cutoff \( r_c \) as defined by the switching function

\[ S_3(r) = \begin{cases} 
1 & \text{if } r < r_c - w \\
3x^2 - 2x^3 & \text{if } r < r_c \text{ with } x = \frac{r - r_c}{w} \\
0 & \text{if } r \geq r_c
\end{cases} \]

where \( w \) is the width defined in the arguments. This potential is combined with Coulomb interaction between Gaussian charge densities:

\[ E = \frac{q_i q_j \text{erf} \left( r / \sqrt{\gamma_1^2 + \gamma_2^2} \right)}{\epsilon r_{ij}} \]

where \( q_i \) and \( q_j \) are the charges on the 2 atoms, \( \epsilon \) is the dielectric constant which can be set by the **dielectric** command, \( \gamma_1 \) and \( \gamma_2 \) are the widths of the Gaussian charge distribution and \( \text{erf}() \) is the error-function. This style has to be used in conjunction with the **kspace_style** command.

If one cutoff is specified it is used for both the vdW and Coulomb terms. If two cutoffs are specified, the first is used as the cutoff for the vdW terms, and the second is the cutoff for the Coulombic term.

The following coefficients must be defined for each pair of atoms types via the **pair_coeff** command as in the examples above, or in the data file or restart files read by the **read_data** or **read_restart** commands:

- \( \epsilon \) (energy)
• $\sigma$ (distance)
• $\gamma$ (distance)

Mixing, shift, table, tail correction, restart, rRESPA info:
Shifting the potential energy is not necessary because the switching function ensures that the potential is zero at the cut-off.

18.307.4 Restrictions
These styles are part of the USER-YAFF package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.307.5 Related commands
pair_coeff
Default: none

18.308 pair_style local/density command

18.308.1 Syntax
pair_style style arg

• style = local/density
• arg = name of file containing tabulated values of local density and the potential

18.308.2 Examples
pair_style local/density benzene_water.localdensity.table
pair_style hybrid/overlay table spline 500 local/density
pair_coeff * * local/density benzene_water.localdensity.table

18.308.3 Description
The local density (LD) potential is a mean-field manybody potential, and, in some sense, a generalization of embedded atom models (EAM). The name “local density potential” arises from the fact that it assigns an energy to an atom depending on the number of neighboring atoms of given type around it within a predefined spherical volume (i.e., within a cutoff). The bottom-up coarse-graining (CG) literature suggests that such potentials can be widely useful in capturing effective multibody forces in a computationally efficient manner so as to improve the quality of CG models of implicit solvation:ref:(Sanyal1) <Sanyal1> and phase-segregation in liquid mixtures:ref:(Sanyal2) <Sanyal2>, and provide guidelines to determine the extent of manybody correlations present in a CG model:ref:(Rosenberger) <Rosenberger> The LD potential in LAMMPS is primarily intended to be used as a corrective potential over traditional pair potentials in bottom-up CG models, i.e., as a hybrid pair style with other explicit pair interaction terms (e.g.,
table spline, Lennard Jones, etc.). Because the LD potential is not a pair potential per se, it is implemented simply as a single auxiliary file with all specifications that will be read upon initialization.

**Note:** Thus when used as the only interaction in the system, there is no corresponding pair_coeff command and when used with other pair styles using the hybrid/overlay option, the corresponding pair_coeff command must be supplied as placeholders for the atom types.

### System with a single CG atom type:

A system of a single atom type (e.g., LJ argon) with a single local density (LD) potential would have an energy given by:

\[ U_{LD} = \sum_i F(\rho_i) \]

where \( \rho_i \) is the LD at atom \( i \) and \( F(\rho) \) is similar in spirit to the embedding function used in EAM potentials. The LD at atom \( i \) is given by the sum

\[ \rho_i = \sum_{j \neq i} \varphi(r_{ij}) \]

where \( \varphi \) is an indicator function that is one at \( r=0 \) and zero beyond a cutoff distance \( R_2 \). The choice of the functional form of \( \varphi \) is somewhat arbitrary, but the following piecewise cubic function has proven sufficiently general: \[(Sanyal1), (Sanyal2) (Rosenberger)\]

\[ \varphi(r) = \begin{cases} 
1 & r \leq R_1, \\
 c_0 + c_2 r^2 + c_4 r^4 + c_6 r^6 & r \in (R_1, R_2), \\
0 & r \geq R_2 
\end{cases} \]

The constants \( c \) are chosen so that the indicator function smoothly interpolates between 1 and 0 between the distances \( R_1 \) and \( R_2 \), which are called the inner and outer cutoffs, respectively. Thus \( \varphi \) satisfies \( \varphi(R_1) = 1 \), \( \varphi(R_2) = \varphi'(R_1) = \varphi'(R_2) = 0 \). The embedding function \( F(\rho) \) may or may not have a closed-form expression. To maintain generality, it is practically represented with a spline-interpolated table over a predetermined range of \( \rho \). Outside of that range it simply adopts zero values at the endpoints.

It can be shown that the total force between two atoms due to the LD potential takes the form of a pair force, which motivates its designation as a LAMMPS pair style. Please see \( (Sanyal1) \) for details of the derivation.

### Systems with arbitrary numbers of atom types:

The potential is easily generalized to systems involving multiple atom types:

\[ U_{LD} = \sum_i a_\alpha F(\rho_i) \]

with the LD expressed as

\[ \rho_i = \sum_{j \neq i} b_\beta \varphi(r_{ij}) \]

where \( \alpha \) gives the type of atom \( i \), \( \beta \) the type of atom \( j \), and the coefficients \( a \) and \( b \) filter for atom types as specified by the user. \( a \) is called the central atom filter as it determines to which atoms the potential applies; \( a_\alpha = 1 \) if the LD potential applies to atom type \( \alpha \) else zero. On the other hand, \( b \) is called the neighbor atom filter because it specifies which atom types to use in the calculation of the LD; \( b_\beta = 1 \) if atom type \( \beta \) contributes to the LD and zero otherwise.
Note: Note that the potentials need not be symmetric with respect to atom types, which is the reason for two distinct sets of coefficients $a$ and $b$. An atom type may contribute to the LD but not the potential, or to the potential but not the LD. Such decisions are made by the user and should (ideally) be motivated on physical grounds for the problem at hand.

General form for implementation in LAMMPS:

Of course, a system with many atom types may have many different possible LD potentials, each with their own atom type filters, cutoffs, and embedding functions. The most general form of this potential as implemented in the pair_style local/density is:

$$ U_{\text{LD}} = \sum_{k} u_{\text{LD}}^{(k)} = \sum_{i} \left[ \sum_{k} a_{\alpha}^{(k)} F^{(k)} \left( \rho_{i}^{(k)} \right) \right] $$

where, $k$ is an index that spans the (arbitrary) number of applied LD potentials $N_{\text{LD}}$. Each LD is calculated as before with:

$$ \rho_{i}^{(k)} = \sum_{j} b_{\beta}^{(k)} \varphi^{(k)}(r_{ij}) $$

The superscript on the indicator function $\varphi$ simply indicates that it is associated with specific values of the cutoff distances $R_{1}(k)$ and $R_{2}(k)$. In summary, there may be $N_{\text{LD}}$ distinct LD potentials. With each potential type $(k)$, one must specify:

- the inner and outer cutoffs as $R_{1}$ and $R_{2}$
- the central type filter $a(k)$, where $k = 1,2,\ldots N_{\text{LD}}$
- the neighbor type filter $b(k)$, where $k = 1,2,\ldots N_{\text{LD}}$
- the LD potential function $F(k)(\rho)$, typically as a table that is later spline-interpolated

Tabulated input file format:

| Line 1: | comment or blank (ignored) |
| Line 2: | comment or blank (ignored) |
| Line 3: | $N_{\text{LD}}$ $N_{\text{rho}}$ (# of LD potentials and # of tabulated values, single space separated) |
| Line 4: | blank (ignored) |
| Line 5: | $R_{1}(k)$ $R_{2}(k)$ (lower and upper cutoffs, single space separated) |
| Line 6: | central-types (central atom types, single space separated) |
| Line 7: | neighbor-types (neighbor atom types single space separated) |
| Line 8: | $\rho_{\min}$ $\rho_{\max}$ $\text{drho}$ (min, max and diff. in tabulated rho values, single space separated) |
| Line 9: | $F(k)(\rho_{\min} + 0.\text{drho})$ |
| Line 10: | $F(k)(\rho_{\min} + 1.\text{drho})$ |
| Line 11: | $F(k)(\rho_{\min} + 2.\text{drho})$ |
| ... | |
| Line $9+N_{\text{rho}}$: | $F(k)(\rho_{\min} + N_{\text{rho}} \cdot \text{drho})$ |
| Line $10+N_{\text{rho}}$: | blank (ignored) |

Block 2

Block 3

Block $N_{\text{LD}}$
Lines 5 to 9+N_rhoe constitute the first block. Thus the input file is separated (by blank lines) into N_LD blocks each representing a separate LD potential and each specifying its own upper and lower cutoffs, central and neighbor atoms, and potential. In general, blank lines anywhere are ignored.

**Mixing, shift, table, tail correction, restart, info:** This pair style does not support automatic mixing. For atom type pairs $\alpha$, $\beta$ and $\alpha \neq \beta$, even if LD potentials of type $(\alpha, \alpha)$ and $(\beta, \beta)$ are provided, you will need to explicitly provide LD potential types $(\alpha, \beta)$ and $(\beta, \alpha)$ if need be (Here, the notation $(\alpha, \beta)$ means that $\alpha$ is the central atom to which the LD potential is applied and $\beta$ is the neighbor atom which contributes to the LD potential on $\alpha$).

This pair style does not support the `pair_modify` shift, table, and tail options.

The local/density pair style does not write its information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

### 18.308.4 Restrictions

The local/density pair style is a part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

### 18.311 pair_style lubricate/poly command

### 18.312 pair_style lubricate/poly/omp command

#### 18.312.1 Syntax

```
pair_style style mu flaglog flagfld cutinner cutoff flagHI flagVF
```

- `style = lubricate` or `lubricate/poly`
- `mu =` dynamic viscosity (dynamic viscosity units)
• flaglog = 0/1 to exclude/include log terms in the lubrication approximation
• flagfld = 0/1 to exclude/include Fast Lubrication Dynamics (FLD) effects
• cutinner = inner cutoff distance (distance units)
• cutoff = outer cutoff for interactions (distance units)
• flagHI (optional) = 0/1 to exclude/include 1/r hydrodynamic interactions
• flagVF (optional) = 0/1 to exclude/include volume fraction corrections in the long-range isotropic terms

18.312.2 Examples

(all assume radius = 1)

```plaintext
pair_style lubricate 1.5 1 1 2.01 2.5
pair_coeff 1 1 2.05 2.8
pair_coeff * *

pair_style lubricate 1.5 1 1 2.01 2.5
pair_coeff * *
variable mu equal ramp(1,2)
fix 1 all adapt 1 pair lubricate mu * * v_mu
```

18.312.3 Description

Styles `lubricate` and `lubricate/poly` compute hydrodynamic interactions between mono-disperse finite-size spherical particles in a pairwise fashion. The interactions have 2 components. The first is Ball-Melrose lubrication terms via the formulas in *(Ball and Melrose)*

\[
W = -a_{sq}(v_1 - v_2) \cdot mm^2 - a_{sh}(\omega_1 + \omega_2) \cdot (I - mm) - 2\Omega_N|\omega_1 - \omega_2|^2 \\
\Omega_N = n \times (v_1 - v_2)/r
\]

which represents the dissipation W between two nearby particles due to their relative velocities in the presence of a background solvent with viscosity \(\mu\). Note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity.

The Asq (squeeze) term is the strongest and is included if `flagHI` is set to 1 (default). It scales as 1/gap where gap is the separation between the surfaces of the 2 particles. The Ash (shear) and Apu (pump) terms are only included if `flaglog` is set to 1. They are the next strongest interactions, and the only other singular interaction, and scale as log(gap). Note that `flaglog` = 1 and `flagHI` = 0 is invalid, and will result in a warning message, after which `flagHI` will be set to 1. The Atw (twist) term is currently not included. It is typically a very small contribution to the lubrication forces.

The `flagHI` and `flagVF` settings are optional. Neither should be used, or both must be defined.

`Cutinner` sets the minimum center-to-center separation that will be used in calculations irrespective of the actual separation. `Cutoff` is the maximum center-to-center separation at which an interaction is computed. Using a `cutoff` less than 3 radii is recommended if `flaglog` is set to 1.

The other component is due to the Fast Lubrication Dynamics (FLD) approximation, described in *(Kumar)*, which can be represented by the following equation

\[
F^H = -R_{FU}(U - U^\infty) + R_{FE}E^\infty
\]
where \( U \) represents the velocities and angular velocities of the particles, \( U^\infty \) represents the velocity and the angular velocity of the undisturbed fluid, and \( E^\infty \) represents the rate of strain tensor of the undisturbed fluid with viscosity \( \mu \). Again, note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity. Volume fraction corrections to \( R_{FU} \) are included as long as \( flagVF \) is set to 1 (default).

**Note:** When using the FLD terms, these pair styles are designed to be used with explicit time integration and a correspondingly small timestep. Thus either `fix nve/sphere` or `fix nve/asphere` should be used for time integration. To perform implicit FLD, see the `pair_style lubricateU` command.

Style `lubricate` requires monodisperse spherical particles; style `lubricate/poly` allows for polydisperse spherical particles.

The viscosity \( \mu \) can be varied in a time-dependent manner over the course of a simulation, in which case the `pair_style` setting for \( \mu \) will be overridden. See the `fix adapt` command for details.

If the suspension is sheared via the `fix deform` command then the pair style uses the shear rate to adjust the hydrodynamic interactions accordingly. Volume changes due to fix deform are accounted for when computing the volume fraction corrections to \( R_{FU} \).

When computing the volume fraction corrections to \( R_{FU} \), the presence of walls (whether moving or stationary) will affect the volume fraction available to colloidal particles. This is currently accounted for with the following types of walls: `wall/lj93`, `wall/lj126`, `wall/collloid`, and `wall/harmonic`. For these wall styles, the correct volume fraction will be used when walls do not coincide with the box boundary, as well as when walls move and thereby cause a change in the volume fraction. Other wall styles will still work, but they will result in the volume fraction being computed based on the box boundaries.

Since lubrication forces are dissipative, it is usually desirable to thermostat the system at a constant temperature. If Brownian motion (at a constant temperature) is desired, it can be set using the `pair_style brownian` command. These pair styles and the brownian style should use consistent parameters for \( \mu \), `flaglog`, `flagfld`, `cutinner`, `cutoff`, `flagHI` and `flagVF`.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- `cutinner` (distance units)
- `cutoff` (distance units)

The two coefficients are optional. If neither is specified, the two cutoffs specified in the `pair_style` command are used. Otherwise both must be specified.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed in this section of the manual. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See this section of the manual for more instructions on how to use the accelerated styles effectively.
Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, the two cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.312.4 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Only spherical monodisperse particles are allowed for pair_style lubricate.

Only spherical particles are allowed for pair_style lubricate/poly.

These pair styles will not restart exactly when using the read_restart command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the read_restart command for more details.

18.312.5 Related commands

pair_coeff, pair_style lubricateU

18.312.6 Default

The default settings for the optional args are flagHI = 1 and flagVF = 1.

(Ball) Ball and Melrose, Physica A, 247, 444-472 (1997).

18.313 pair_style lubricateU command

18.314 pair_style lubricateU/poly command

18.314.1 Syntax

```
pair_style style mu flaglog cutinner cutoff gdot flagHI flagVF
```

- `style = lubricateU` or `lubricateU/poly`
- `mu =` dynamic viscosity (dynamic viscosity units)
- `flaglog =` 0/1 to exclude/include log terms in the lubrication approximation
- `cutinner =` inner cut off distance (distance units)
- `cutoff =` outer cutoff for interactions (distance units)
- `gdot =` shear rate (1/time units)
- `flagHI (optional) =` 0/1 to exclude/include 1/r hydrodynamic interactions
- `flagVF (optional) =` 0/1 to exclude/include volume fraction corrections in the long-range isotropic terms

18.314.2 Examples

(all assume radius = 1)

```
pair_style lubricateU 1.5 1 2.01 2.5 0.01 1 1
pair_coeff 1 1 2.05 2.8
pair_coeff * *
```

18.314.3 Description

Styles `lubricateU` and `lubricateU/poly` compute velocities and angular velocities for finite-size spherical particles such that the hydrodynamic interaction balances the force and torque due to all other types of interactions.

The interactions have 2 components. The first is Ball-Melrose lubrication terms via the formulas in (Ball and Melrose)

\[
W = -a_{sq}(|v_1 - v_2| \cdot nn)^2 - a_{sh}|(\omega_1 + \omega_2) \cdot (I - nn) - 2\Omega_N|^2 -
\]

\[
a_{pu}|(\omega_1 - \omega_2) \cdot (I - nn)|^2 - a_{tw}|(\omega_1 - \omega_2) \cdot nn|^2 \quad r < r_c
\]

\[
\Omega_N = n \times (v_1 - v_2)/r
\]

which represents the dissipation \( W \) between two nearby particles due to their relative velocities in the presence of a background solvent with viscosity \( \mu \). Note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity.

The Asq (squeeze) term is the strongest and is included as long as `flagHI` is set to 1 (default). It scales as 1/gap where gap is the separation between the surfaces of the 2 particles. The Ash (shear) and Apu (pump) terms are only included if `flaglog` is set to 1. They are the next strongest interactions, and the only other singular interaction, and scale as \( \log(\text{gap}) \). Note that `flaglog = 1` and `flagHI = 0` is invalid, and will result in a warning message, after which `flagHI` will be set to 1. The Atw (twist) term is currently not included. It is typically a very small contribution to the lubrication forces.
The `flagHI` and `flagVF` settings are optional. Neither should be used, or both must be defined. `Cutinner` sets the minimum center-to-center separation that will be used in calculations irrespective of the actual separation. `Cutoff` is the maximum center-to-center separation at which an interaction is computed. Using a `cutoff` less than 3 radii is recommended if `flaglog` is set to 1.

The other component is due to the Fast Lubrication Dynamics (FLD) approximation, described in (Kumar). The equation being solved to balance the forces and torques is

\[
-R_{FU}(U - U^\infty) = -R_{FE}E^\infty - F_{rest}
\]

where \( U \) represents the velocities and angular velocities of the particles, \( U^\infty \) represents the velocities and the angular velocities of the undisturbed fluid, and \( E^\infty \) represents the rate of strain tensor of the undisturbed fluid flow with viscosity \( \mu \). Again, note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity. Volume fraction corrections to \( R_{FU} \) are included if `flagVF` is set to 1 (default).

`F_{rest}` represents the forces and torques due to all other types of interactions, e.g. Brownian, electrostatic etc. Note that this algorithm neglects the inertial terms, thereby removing the restriction of resolving the small interial time scale, which may not be of interest for colloidal particles. This pair style solves for the velocity such that the hydrodynamic force balances all other types of forces, thereby resulting in a net zero force (zero inertia limit). When defining this pair style, it must be defined last so that when this style is invoked all other types of forces have already been computed. For the same reason, it won’t work if additional non-pair styles are defined (such as bond or Kspace forces) as they are calculated in LAMMPS after the pairwise interactions have been computed.

**Note:** When using these styles, the these pair styles are designed to be used with implicit time integration and a correspondingly larger timestep. Thus either `fix nve/noforce` should be used for spherical particles defined via `atom_style sphere` or `fix nve/asphere/noforce` should be used for spherical particles defined via `atom_style ellipsoid`. This is because the velocity and angular momentum of each particle is set by the pair style, and should not be reset by the time integration fix.

Style `lubricateU` requires monodisperse spherical particles; style `lubricateU/poly` allows for polydisperse spherical particles.

If the suspension is sheared via the `fix deform` command then the pair style uses the shear rate to adjust the hydrodynamic interactions accordingly. Volume changes due to `fix deform` are accounted for when computing the volume fraction corrections to \( R_{FU} \).

When computing the volume fraction corrections to \( R_{FU} \), the presence of walls (whether moving or stationary) will affect the volume fraction available to colloidal particles. This is currently accounted for with the following types of walls: `wall/lj93`, `wall/lj126`, `wall/colloid`, and `wall/harmonic`. For these wall styles, the correct volume fraction will be used when walls do not coincide with the box boundary, as well as when walls move and thereby cause a change in the volume fraction. To use these wall styles with `pair_style lubricateU` or `lubricateU/poly`, the `fld yes` option must be specified in the fix wall command.

Since lubrication forces are dissipative, it is usually desirable to thermostat the system at a constant temperature. If Brownian motion (at a constant temperature) is desired, it can be set using the `pair_style brownian` command. These pair styles and the brownian style should use consistent parameters for \( \mu, \text{flaglog}, \text{flagfld}, \text{cutinner}, \text{cutoff}, \text{flagHI} \) and `flagVF`.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- cutinner (distance units)
- cutoff (distance units)
The two coefficients are optional. If neither is specified, the two cutoffs specified in the pair_style command are used. Otherwise both must be specified.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

For atom type pairs IJ and I \(!= J\), the two cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the `pair_modify` shift option for the energy of the pair interaction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 18.314.4 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

Currently, these pair styles assume that all other types of forces/torques on the particles have been already been computed when it is invoked. This requires this style to be defined as the last of the pair styles, and that no fixes apply additional constraint forces. One exception is the `fix wall/colloid` commands, which has an “fld” option to apply their wall forces correctly.

Only spherical monodisperse particles are allowed for pair_style lubricateU.

Only spherical particles are allowed for pair_style lubricateU/poly.

For sheared suspensions, it is assumed that the shearing is done in the xy plane, with x being the velocity direction and y being the velocity-gradient direction. In this case, one must use `fix deform` with the same rate of shear (erate).

18.317.3 Description

The lj/mdf, buck/mdf and lennard/mdf compute the standard 12-6 Lennard-Jones and Buckingham potential with the addition of a taper function that ramps the energy and force smoothly to zero between an inner and outer cutoff.

\[ E_{\text{smooth}}(r) = E(r) \times f(r) \]

The tapering, \( f(r) \), is done by using the Mei, Davenport, Fernando function (Mei).

\[
\begin{align*}
    f(r) &= 1.0 & \text{for } & r < r_m \\
    f(r) &= (1 - x)^3 \ast (1 + 3x + 6x^2) & \text{for } & r_m < r < r_{\text{cut}} \\
    f(r) &= 0.0 & \text{for } & r \geq r_{\text{cut}}
\end{align*}
\]
where

\[ x = \frac{(r - r_m)}{(r_{cut} - r_m)} \]

Here \( r_m \) is the inner cutoff radius and \( r_{cut} \) is the outer cutoff radius.

For the \textit{lj/mdf} pair\_style, the potential energy, \( E(r) \), is the standard 12-6 Lennard-Jones written in the epsilon/sigma form:

\[ E(r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \]

Either the first two or all of the following coefficients must be defined for each pair of atoms types via the pair\_coeff command as in the examples above, or in the data file read by the \textit{read\_data}. The two cutoffs default to the global values and \( \epsilon \) and \( \sigma \) can also be determined by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- \( r_m \) (distance units)
- \( r_{cut} \) (distance units)

For the \textit{buck/mdf} pair\_style, the potential energy, \( E(r) \), is the standard Buckingham potential with three required coefficients. The two cutoffs can be omitted and default to the corresponding global values:

\[ E(r) = Ae^{(-r/\rho)} - \frac{C}{r^6} \]

- \( A \) (energy units)
- \( \rho \) (distance units)
- \( C \) (energy-distance\(^6\) units)
- \( r_m \) (distance units)
- \( r_{cut} \) (distance units)

For the \textit{lennard/mdf} pair\_style, the potential energy, \( E(r) \), is the standard 12-6 Lennard-Jones written in the A/B form:

\[ E(r) = \frac{A}{r^{12}} - \frac{B}{r^6} \]

The following coefficients must be defined for each pair of atoms types via the pair\_coeff command as in the examples above, or in the data file read by the \textit{read\_data} commands, or by mixing as described below. The two cutoffs default to their global values and must be either both given or both left out:

- \( A \) (energy-distance\(^12\) units)
- \( B \) (energy-distance\(^6\) units)
- \( r_m \) (distance units)
- \( r_{cut} \) (distance units)
Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, the $\epsilon$ and $\sigma$ coefficients and cutoff distances for the lj/mdf pair style can be mixed. The default mix value is geometric. See the "pair_modify" command for details. The other two pair styles buck/mdf and lennard/mdf do not support mixing, so all I,J pairs of coefficients must be specified explicitly.

None of the lj/mdf, buck/mdf, or lennard/mdf pair styles supports the pair_modify shift option or long-range tail corrections to pressure and energy.

These styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

18.317.4 Restrictions

These pair styles can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

18.319.3 Description

The `meam/spline` style computes pairwise interactions for metals using a variant of modified embedded-atom method (MEAM) potentials (Lenosky). For a single species (“old-style”) MEAM, the total energy $E$ is given by

$$E = \sum_{i<j} \phi(r_{ij}) + \sum_{i} U(n_i)$$

$$n_i = \sum_{j} \rho(r_{ij}) + \sum_{j<k, j,k \neq i} f(r_{ij}) f(r_{ik}) g[\cos(\theta_{jik})]$$

where $\rho_i$ is the density at atom $i$, $\theta_{jik}$ is the angle between atoms $J$, $I$, and $K$ centered on atom $I$. The five functions $\phi, U, \rho, f,$ and $g$ are represented by cubic splines.

The `meam/spline` style also supports a new style multicomponent modified embedded-atom method (MEAM) potential (Zhang), where the total energy $E$ is given by

$$E = \sum_{i<j} \phi_{ij}(r_{ij}) + \sum_{i} U_i(n_i)$$

$$n_i = \sum_{j \neq i} \rho_j(r_{ij}) + \sum_{j<k, j,k \neq i} f_{ij}(r_{ij}) f_{ik}(r_{ik}) g_{jk}[\cos(\theta_{jik})]$$

where the five functions $\phi, U, \rho, f,$ and $g$ depend on the chemistry of the atoms in the interaction. In particular, if there are $N$ different chemistries, there are $N$ different $U, \rho,$ and $f$ functions, while there are $N(N+1)/2$ different $\phi$ and $g$ functions. The new style multicomponent MEAM potential files are indicated by the second line in the file starts with “meam/spline” followed by the number of elements and the name of each element.

The cutoffs and the coefficients for these spline functions are listed in a parameter file which is specified by the `pair_coeff` command. Parameter files for different elements are included in the “potentials” directory of the LAMMPS distribution and have a “.meam.spline” file suffix. All of these files are parameterized in terms of LAMMPS metal units.

Note that unlike for other potentials, cutoffs for spline-based MEAM potentials are not set in the `pair_style` or `pair_coeff` command; they are specified in the potential files themselves.

Unlike the EAM pair style, which retrieves the atomic mass from the potential file, the spline-based MEAM potentials do not include mass information; thus you need to use the `mass` command to specify it.

Only a single `pair_coeff` command is used with the `meam/spline` style which specifies a potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying $N$ additional arguments after the filename in the `pair_coeff` command, where $N$ is the number of LAMMPS atom types:

- `filename`
- `N element names = mapping of spline-based MEAM elements to atom types`

See the `pair_coeff` doc page for alternate ways to specify the path for the potential file.

As an example, imagine the Ti.meam.spline file has values for Ti (old style). If your LAMMPS simulation has 3 atoms types and they are all to be treated with this potentials, you would use the following `pair_coeff` command:

```
pair_coeff * * Ti.meam.spline Ti Ti Ti
```

The first 2 arguments must be `* *` so as to span all LAMMPS atom types. The three Ti arguments map LAMMPS atom types 1,2,3 to the Ti element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a `meam/spline` potential is used as part of the `hybrid` pair style. The NULL values are placeholders for atom types that will be used with other potentials. The old-style potential maps any non-NULL species named on the command line to that single type.

An example with a two component spline (new style) is TiO.meam.spline, where the command
**pair_coeff** * * TiO.meam.spline Ti O

will map the first atom type to Ti and the second atom type to O. Note in this case that the species names need to match exactly with the names of the elements in the TiO.meam.spline file; otherwise an error will be raised. This behavior is different than the old style MEAM files.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support the `pair_modify` shift, table, and tail options.

The `meam/spline` pair style does not write its information to binary restart files, since it is stored in an external potential parameter file. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

The `meam/spline` pair style can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.

**18.319.4 Restrictions**

This pair style requires the `newton` setting to be “on” for pair interactions.

This pair style is only enabled if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

**18.319.5 Related commands**

`pair_coeff`, `pair_style meam/c`

### 18.320 pair_style meam/sw/spline command

#### 18.320.1 Syntax

```
pair_style meam/sw/spline
```

#### 18.320.2 Examples

```
pair_style meam/sw/spline
pair_coeff * * Ti.meam.sw.spline Ti
pair_coeff * * Ti.meam.sw.spline Ti Ti Ti
```

#### 18.320.3 Description

The `meam/sw/spline` style computes pairwise interactions for metals using a variant of modified embedded-atom method (MEAM) potentials (Lenosky) with an additional Stillinger-Weber (SW) term (Stillinger) in the energy. This form of the potential was first proposed by Nicklas, Fellinger, and Park (Nicklas). We refer to it as MEAM+SW. The total energy $E$ is given by

\[
E = E_{MEAM} + E_{SW}
\]

\[
E_{MEAM} = \sum_{IJ} \phi(r_{IJ}) + \sum_{I} U(\rho_I)
\]

\[
E_{SW} = \sum_{I} \sum_{JK} F(r_{IJ}) F(r_{IK}) G(\cos(\theta_{JIK}))
\]

\[
\rho_I = \sum_{J} \rho(r_{IJ}) + \sum_{JK} f(r_{IJ}) f(r_{IK}) g(\cos(\theta_{JIK}))
\]

where $\rho_I$ is the density at atom I, $\theta_{JIK}$ is the angle between atoms J, I, and K centered on atom I. The seven functions $\phi, F, G, U, \rho, f,$ and $g$ are represented by cubic splines.

The cutoffs and the coefficients for these spline functions are listed in a parameter file which is specified by the `pair_coeff` command. Parameter files for different elements are included in the “potentials” directory of the LAMMPS distribution and have a “.meam.sw.spline” file suffix. All of these files are parameterized in terms of LAMMPS metal units.

Note that unlike for other potentials, cutoffs for spline-based MEAM+SW potentials are not set in the pair_style or pair_coeff command; they are specified in the potential files themselves.

Unlike the EAM pair style, which retrieves the atomic mass from the potential file, the spline-based MEAM+SW potentials do not include mass information; thus you need to use the `mass` command to specify it.

Only a single `pair_coeff` command is used with the `meam/sw/spline` style which specifies a potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- `filename`
- N element names = mapping of spline-based MEAM+SW elements to atom types

See the `pair_coeff` doc page for alternate ways to specify the path for the potential file.

As an example, imagine the `Ti.meam.sw.spline` file has values for Ti. If your LAMMPS simulation has 3 atoms types and they are all to be treated with this potential, you would use the following `pair_coeff` command:
**pair_coeff** * * Ti.meam.sw.spline Ti Ti Ti

The first 2 arguments must be * * so as to span all LAMMPS atom types. The three Ti arguments map LAMMPS atom types 1,2,3 to the Ti element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a meam/sw/spline potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

**Note:** The meam/sw/spline style currently supports only single-element MEAM+SW potentials. It may be extended for alloy systems in the future.

Example input scripts that use this pair style are provided in the examples/USER/misc/meam_sw_spline directory.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

The pair style does not support multiple element types or mixing. It has been designed for pure elements only.

This pair style does not support the pair_modify shift, table, and tail options.

The meam/sw/spline pair style does not write its information to binary restart files, since it is stored in an external potential parameter file. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

The meam/sw/spline pair style can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

18.320.4 Restrictions

This pair style requires the newton setting to be “on” for pair interactions.

This pair style is only enabled if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

```

18.321.3 Description

**Note:** The behavior of the MEAM potential for alloy systems has changed as of November 2010; see description below of the mixture_ref_t parameter.

Style `meam/c` computes pairwise interactions for a variety of materials using modified embedded-atom method (MEAM) potentials (Baskes). Conceptually, it is an extension to the original EAM potentials which adds angular forces. It is thus suitable for modeling metals and alloys with fcc, bcc, hcp and diamond cubic structures, as well as covalently bonded materials like silicon and carbon. Style `meam/c` is a translation of the (now obsolete) `meam` code from Fortran to C++. It is functionally equivalent to `meam` but more efficient, and thus `meam` has been removed from LAMMPS after the 12 December 2018 release.

In the MEAM formulation, the total energy $E$ of a system of atoms is given by:

$$
E = \sum_i \left\{ F_i(\bar{\rho}_i) + \frac{1}{2} \sum_{i \neq j} \phi_{ij}(r_{ij}) \right\}
$$

where $F$ is the embedding energy which is a function of the atomic electron density $\rho$, and $\phi$ is a pair potential interaction. The pair interaction is summed over all neighbors $J$ of atom $I$ within the cutoff distance. As with EAM, the multi-body nature of the MEAM potential is a result of the embedding energy term. Details of the computation of the embedding and pair energies, as implemented in LAMMPS, are given in (Gullet) and references therein.

The various parameters in the MEAM formulas are listed in two files which are specified by the `pair_coeff` command. These are ASCII text files in a format consistent with other MD codes that implement MEAM potentials, such as the serial DYNAMO code and Warp. Several MEAM potential files with parameters for different materials are included in the "potentials" directory of the LAMMPS distribution with a "meam" suffix. All of these are parameterized in terms of LAMMPS metal units.

Note that unlike for other potentials, cutoffs for MEAM potentials are not set in the pair_style or pair_coeff command; they are specified in the MEAM potential files themselves.

Only a single `pair_coeff` command is used with the `meam` style which specifies two MEAM files and the element(s) to extract information for. The MEAM elements are mapped to LAMMPS atom types by specifying $N$ additional arguments after the second filename in the `pair_coeff` command, where $N$ is the number of LAMMPS atom types:

- MEAM library file
- Elem1, Elem2, ...
- MEAM parameter file
• N element names = mapping of MEAM elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential files.

As an example, the potentials/library.meam file has generic MEAM settings for a variety of elements. The potentials/SiC.meam file has specific parameter settings for a Si and C alloy system. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * library.meam Si C sic.meam Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first filename is the element library file. The list of elements following it extracts lines from the library file and assigns numeric indices to these elements. The second filename is the alloy parameter file, which refers to elements using the numeric indices assigned before. The arguments after the parameter file map LAMMPS atom types to elements, i.e. LAMMPS atom types 1,2,3 to the MEAM Si element. The final C argument maps LAMMPS atom type 4 to the MEAM C element.

If the second filename is specified as NULL, no parameter file is read, which simply means the generic parameters in the library file are used. Use of the NULL specification for the parameter file is discouraged for systems with more than a single element type (e.g. alloys), since the parameter file is expected to set element interaction terms that are not captured by the information in the library file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when a meam potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

**Note:** If the second filename is NULL, the element names between the two filenames can appear in any order, e.g. “Si C” or “C Si” in the example above. However, if the second filename is not NULL (as in the example above), it contains settings that are Fortran-indexed for the elements that precede it. Thus you need to insure you list the elements between the filenames in an order consistent with how the values in the second filename are indexed. See details below on the syntax for settings in the second file.

The MEAM library file provided with LAMMPS has the name potentials/library.meam. It is the “meamf” file used by other MD codes. Aside from blank and comment lines (start with #) which can appear anywhere, it is formatted as a series of entries, each of which has 19 parameters and can span multiple lines:

```
elt, lat, z, ielement, atwt, alpha, b0, b1, b2, b3, alat, esub, asub, t0, t1, t2, t3, rozero, ibar
```

The “elt” and “lat” parameters are text strings, such as elt = Si or Cu and lat = dia or fcc. Because the library file is used by Fortran MD codes, these strings may be enclosed in single quotes, but this is not required. The other numeric parameters match values in the formulas above. The value of the “elt” string is what is used in the pair_coeff command to identify which settings from the library file you wish to read in. There can be multiple entries in the library file with the same “elt” value; LAMMPS reads the first matching entry it finds and ignores the rest.

Other parameters in the MEAM library file correspond to single-element potential parameters:

```
lat = lattice structure of reference configuration
z = number of nearest neighbors in the reference structure
ielement = atomic number
atwt = atomic weight
alat = lattice constant of reference structure
esub = energy per atom (eV) in the reference structure at equilibrium
asub = "A" parameter for MEAM (see e.g. (Baskes))
```

The alpha, b0, b1, b2, b3, t0, t1, t2, t3 parameters correspond to the standard MEAM parameters in the literature (Baskes) (the b parameters are the standard beta parameters). Note that only parameters normalized to t0 = 1.0 are supported. The rozero parameter is an element-dependent density scaling that weights the reference background density (see e.g. equation 4.5 in (Gullet)) and is typically 1.0 for single-element systems. The ibar parameter selects the form of the function G(Gamma) used to compute the electron density; options are 18.321. pair_style meam/c command
0 => \( G = \sqrt{1+\Gamma} \)
1 => \( G = \exp(\Gamma/2) \)
2 => not implemented
3 => \( G = 2/(1+\exp(-\Gamma)) \)
4 => \( G = \sqrt{1+\Gamma} \)
-5 => \( G = \pm \sqrt{\text{abs}(1+\Gamma)} \)

If used, the MEAM parameter file contains settings that override or complement the library file settings. Examples of such parameter files are in the potentials directory with a “.meam” suffix. Their format is the same as is read by other Fortran MD codes. Aside from blank and comment lines (start with #) which can appear anywhere, each line has one of the following forms. Each line can also have a trailing comment (starting with #) which is ignored.

- keyword = value
- keyword(I) = value
- keyword(I,J) = value
- keyword(I,J,K) = value

The indices I, J, K correspond to the elements selected from the MEAM library file numbered in the order of how those elements were selected starting from 1. Thus for the example given before:

```
pair_coeff * * library.meam Si C sic.meam Si Si Si C
```

an index of 1 would refer to Si and an index of 2 to C.

The recognized keywords for the parameter file are as follows:

- \( \text{rc} \) = cutoff radius for cutoff function; default = 4.0
- \( \text{delr} \) = length of smoothing distance for cutoff function; default = 0.1
- \( \text{rho0(I)} \) = relative density for element I (overwrites value read from meamf file)
- \( \text{Ec(I,J)} \) = cohesive energy of reference structure for I-J mixture
- \( \text{delta(I,J)} \) = heat of formation for I-J alloy; if \( \text{Ec}_{IJ} \) is input as zero, then LAMMPS sets \( \text{Ec}_{IJ} = (\text{Ec}_{II} + \text{Ec}_{JJ})/2 - \text{delta}_{IJ} \)
- \( \text{alpha(I,J)} \) = alpha parameter for pair potential between I and J (can be computed from bulk modulus of reference structure
- \( \text{re(I,J)} \) = equilibrium distance between I and J in the reference structure
- \( \text{Cmax(I,J,K)} \) = Cmax screening parameter when I-J pair is screened by K \((I<=J); \text{default} = 2.8\)
- \( \text{Cmin(I,J,K)} \) = Cmin screening parameter when I-J pair is screened by K \((I<=J); \text{default} = 2.0\)
- \( \text{lattice(I,J)} \) = lattice structure of I-J reference structure:
  - fcc = face centered cubic
  - bcc = body centered cubic
  - hcp = hexagonal close-packed
  - dim = dimer
  - dia = diamond (interlaced fcc for alloy)
  - dia3 = diamond structure with primary 1NN and secondary 3NN
  - interaction
    - b1 = rock salt (NaCl structure)
    - c11 = MoSi2 structure
    - li2 = Cu3Au structure (lower case I, followed by 12)
    - b2 = CsCl structure (interpenetrating simple cubic)
    - ch4 = methane-like structure, only for binary system
    - lin = linear structure (180 degree angle)
    - zig = zigzag structure with a uniform angle
tri = H2O-like structure that has an angle

\[ \text{nn2}(I,J) = \text{turn on second-nearest neighbor MEAM formulation for I-J pair (see for example (Lee)).} \]
0 = second-nearest neighbor formulation off
1 = second-nearest neighbor formulation on
default = 0

\[ \text{attrac}(I,J) = \text{additional cubic attraction term in Rose energy I-J pair} \]
default = 0

\[ \text{repuls}(I,J) = \text{additional cubic repulsive term in Rose energy I-J pair} \]
default = 0

\[ \text{zbl}(I,J) = \text{blend the MEAM I-J pair potential with the ZBL potential for small atom separations (ZBL)} \]
default = 1

\[ \text{theta}(I,J) = \text{angle between three atoms in line, zigzag, and trimer reference structures in degrees} \]
default = 180

\[ \text{gsmooth_factor} = \text{factor determining the length of the G-function smoothing region; only significant for ibar=0 or ibar=4.} \]
99.0 = short smoothing region, sharp step
0.5 = long smoothing region, smooth step
default = 99.0

\[ \text{augt1} = \text{integer flag for whether to augment t1 parameter by 3/5*t3 to account for old vs. new meam formulations;} \]
0 = don't augment t1
1 = augment t1
default = 1

\[ \text{i} = \text{integer flag to use alternative averaging rule for t parameters, for comparison with the DYNAMO MEAM code} \]
0 = standard averaging (matches i=0 in DYNAMO)
1 = alternative averaging (matches i=1 in DYNAMO)
2 = no averaging of t (use single-element values)
default = 0

\[ \text{mixture_ref_t} = \text{integer flag to use mixture average of t to compute the background reference density for alloys, instead of the single-element values} \]
(see description and warning elsewhere in this doc page)
0 = do not use mixture averaging for t in the reference density
1 = use mixture averaging for t in the reference density
default = 0

\[ \text{erose_form} = \text{integer value to select the form of the Rose energy function} \]
(see description below)
default = 0

\[ \text{emb_lin_neg} = \text{integer value to select embedding function for negative densities} \]
0 = F(rho)=0
1 = F(rho) = -asub*esub*rho (linear in rho, matches DYNAMO)
default = 0
The augt1 parameter is related to modifications in the MEAM formulation of the partial electron density function. In recent literature, an extra term is included in the expression for the third-order density in order to make the densities orthogonal (see for example *(Wang)*, equation 3d); this term is included in the MEAM implementation in lammps. However, in earlier published work this term was not included when deriving parameters, including most of those provided in the library.meam file included with lammps, and to account for this difference the parameter t must be augmented by 3/5*t3. If augt1=1, the default, this augmentation is done automatically. When parameter values are fit using the modified density function, as in more recent literature, augt1 should be set to 0.

The mixture_ref_t parameter is available to match results with those of previous versions of lammps (before January 2011). Newer versions of lammps, by default, use the single-element values of the t parameters to compute the background reference density. This is the proper way to compute these parameters. Earlier versions of lammps used an alloy mixture averaged value of t to compute the background reference density. Setting mixture_ref_t=1 gives the old behavior. WARNING: using mixture_ref_t=1 will give results that are demonstrably incorrect for second-neighbor MEAM, and non-standard for first-neighbor MEAM; this option is included only for matching with previous versions of lammps and should be avoided if possible.

The parameters attrac and repuls, along with the integer selection parameter erose_form, can be used to modify the Rose energy function used to compute the pair potential. This function gives the energy of the reference state as a function of interatomic spacing. The form of this function is:

\[ \astar = \alpha * (r/re - 1.0) \]

\[ \text{if } \text{eros_form} = 0: \text{eros} = -Ec*(1+\astar+a3*(\astar**3)/(r/re))*exp(-\astar) \]

\[ \text{if } \text{eros_form} = 1: \text{eros} = -Ec*(1+\astar+(-\text{attrac}+\text{repuls}/r)\astar**3))*exp(-\astar) \]

\[ \text{if } \text{eros_form} = 2: \text{eros} = -Ec*(1 +\astar + a3*(\astar**3))*exp(-\astar) \]

a3 = repuls, \astar < 0
a3 = attrac, \astar >= 0

Most published MEAM parameter sets use the default values attrac=repulse=0. Setting repuls=attrac=delta corresponds to the form used in several recent published MEAM parameter sets, such as *(Valone)*

**Note:** The default form of the erose expression in LAMMPS was corrected in March 2009. The current version is correct, but may show different behavior compared with earlier versions of lammps with the attrac and/or repuls parameters are non-zero. To obtain the previous default form, use erose_form = 1 (this form does not seem to appear in the literature). An alternative form (see e.g. *(Lee)*) is available using erose_form = 2.
Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs \( I, J \) and \( I \neq J \), where types \( I \) and \( J \) correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a pair_coeff command with \( I \neq J \) arguments for this style.

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

18.321.4 Restrictions

The `meam/c` style is provided in the USER-MEAMC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The maximum number of elements, that can be read from the MEAM library file, is determined at compile time. The default is 5. If you need support for more elements, you have to change the define for the constant ‘maxelt’ at the beginning of the file `src/USER-MEAMC/meam.h` and update/recompile LAMMPS. There is no limit on the number of atoms types.

18.322 pair_style mesocnt command

18.322.1 Syntax

```
pair_style mesocnt
```
18.322.2 Examples

```
pair_style mesocnt
pair_coeff * * 10_10.cnt
```

18.322.3 Description

Style `mesocnt` implements a mesoscopic potential for the interaction of carbon nanotubes (CNTs). In this potential, CNTs are modelled as chains of cylindrical segments in which each infinitesimal surface element interacts with all other CNT surface elements with the Lennard-Jones (LJ) term adopted from the `airebo` style. The interaction energy is then computed by integrating over the surfaces of all interacting CNTs.

The potential is based on interactions between one cylindrical segment and infinitely or semi-infinitely long CNTs as described in (Volkov1). Chains of segments are converted to these (semi-)infinite CNTs bases on an approximate chain approach outlined in (Volkov2). This allows to simplify the computation of the interactions significantly and reduces the computational times to the same order of magnitude as for regular bead spring models where beads interact with the standard `pair_lj/cut` potential.

In LAMMPS, cylindrical segments are represented by bonds. Each segment is defined by its two end points (“nodes”) which correspond to atoms in LAMMPS. For the exact functional form of the potential and implementation details, the reader is referred to the original papers (Volkov1) and (Volkov2).

The potential requires tabulated data provided in a single ASCII text file specified in the `pair_coeff` command. The first line of the file provides a time stamp and general information. The second line lists four integers giving the number of data points provided in the subsequent four data tables. The third line lists four floating point numbers: the CNT radius $R$, the LJ parameter $\sigma$ and two numerical parameters $\delta_1$ and $\delta_2$. These four parameters are given in Angstroms. This is followed by four data tables each separated by a single empty line. The first two tables have two columns and list the parameters $u_{\text{InfParallel}}$ and $\Gamma$ respectively. The last two tables have three columns giving data on a quadratic array and list the parameters $\Phi$ and $u_{\text{SemiParallel}}$ respectively. $u_{\text{InfParallel}}$ and $u_{\text{SemiParallel}}$ are given in eV/Angstrom, $\Phi$ is given in eV and $\Gamma$ is unitless.

Potential files for CNTs can be readily generated using the freely available code provided on https://github.com/phankl/cntpot

Using the same approach, it should also be possible to generate potential files for other 1D systems such as boron nitride nanotubes.

**Note:** LAMMPS comes with one `mesocnt` style potential file where the default number of data points per table is 1001. This is sufficient for NVT simulations. For proper energy conservation, we recommend using a potential file where the resolution for $\Phi$ is at least 2001 data points.

**Note:** The `mesocnt` style requires CNTs to be represented as a chain of atoms connected by bonds. Atoms need to be numbered consecutively within one chain. Atoms belonging to different CNTs need to be assigned different molecule IDs.

A full summary of the method and LAMMPS implementation details is expected to soon become available in Computer Physics Communications.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support mixing.
This pair style does not support the `pair_modify` shift, table, and tail options.

The `mesocnt` pair style do not write their information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.

---

### 18.322.4 Restrictions

This style is part of the USER-MESONT package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair potential requires the `newton` setting to be “on” for pair interactions.

18.326.3 Description

The edpd style computes the pairwise interactions and heat fluxes for eDPD particles following the formulations in (Li2014_JCP) and Li2015_CC. The time evolution of an eDPD particle is governed by the conservation of momentum and energy given by

$$\frac{d^2\mathbf{r}_i}{dt^2} = \frac{d\mathbf{v}_i}{dt} = \mathbf{F}_i = \sum_{i\neq j} (\mathbf{F}^C_{ij} + \mathbf{F}^D_{ij} + \mathbf{F}^R_{ij})$$

$$C_v \frac{dT_i}{dt} = q_i = \sum_{i\neq j} (q^C_{ij} + q^V_{ij} + q^R_{ij})$$

where the three components of $F_i$ including the conservative force $F^C_{ij}$, dissipative force $F^D_{ij}$ and random force $F^R_{ij}$ are expressed as

$$\mathbf{F}^C_{ij} = \alpha_{ij}\omega_C(r_{ij})\mathbf{e}_{ij}$$
$$\mathbf{F}^D_{ij} = -\gamma \omega_D(r_{ij})(\mathbf{e}_{ij} \cdot \mathbf{v}_{ij})\mathbf{e}_{ij}$$
$$\mathbf{F}^R_{ij} = \sigma \omega_R(r_{ij})\xi_{ij}\Delta t^{-1/2}\mathbf{e}_{ij}$$

$$\omega_C(r) = 1 - r/r_c$$
$$\alpha_{ij} = A \cdot k_B(T_i + T_j)/2$$
$$\omega_D(r) = \omega^a_D(r) = (1 - r/r_c)^a$$
$$\sigma^2_{ij} = 4\gamma k_B T_i T_j / (T_i + T_j)$$

in which the exponent of the weighting function $s$ can be defined as a temperature-dependent variable. The heat flux between particles accounting for the collisional heat flux $q^C$, viscous heat flux $q^V$, and random heat flux $q^R$ are given
by

\[ q_i^C = \sum_{j \neq i} k_{ij} \omega_{CT}(r_{ij}) \left( \frac{1}{T_i} - \frac{1}{T_j} \right) \]

\[ q_i^V = \frac{1}{2C_v} \sum_{j \neq i} \left\{ \omega_D(r_{ij}) \left[ \gamma_{ij} (e_{ij} \cdot v_{ij})^2 - \frac{(\sigma_{ij})^2}{m} \right] - \sigma_{ij} \omega_R(r_{ij}) (e_{ij} \cdot v_{ij}) \xi_{ij} \right\} \]

\[ q_i^R = \sum_{j \neq i} \beta_{ij} \omega_{RT}(r_{ij}) dt^{-1/2} \xi_{ij}^e \]

\[ \omega_{CT}(r) = \omega_{RT}(r) = (1 - r/r_c)^s_T \]

\[ k_{ij} = C_v^2 \kappa(T_i + T_j)^2 / 4k_B \]

\[ \beta_{ij}^2 = 2k_B k_{ij} \]

where the mesoscopic heat friction \( \kappa \) is given by

\[ \kappa = \frac{315k_B\nu}{2\pi\rho C_v r_c^5 / Pr} \]

with \( \nu \) being the kinematic viscosity. For more details, see Eq.(15) in \( (Li2014_JCP) \).

The following coefficients must be defined in eDPD system for each pair of atom types via the \textit{pair_coeff} command as in the examples above.

- A (force units)
- \( \gamma \) (force/velocity units)
- \textit{power}_f (positive real)
- cutoff (distance units)
- kappa (thermal conductivity units)
- \textit{power}_T (positive real)
- cutoff_T (distance units)
- optional keyword = power or kappa

The keyword \textit{power} or \textit{kappa} is optional. Both “power” and “kappa” require 4 parameters \( c_1, c_2, c_3, c_4 \) showing the temperature dependence of the exponent \( s(T) = \text{power}_f (1 + c_1(T - 1) + c_2(T - 1)^2 + c_3(T - 1)^3 + c_4(T - 1)^4) \) and of the mesoscopic heat friction \( s_T(T) = \kappa(1 + c_1(T - 1) + c_2(T - 1)^2 + c_3(T - 1)^3 + c_4(T - 1)^4). \) If the keyword \textit{power} or \textit{kappa} is not specified, the eDPD system will use constant \textit{power}_f and \( \kappa \), which is independent to temperature changes.

The \textit{mdpd/rhosum} style computes the local particle mass density \( \rho \) for mDPD particles by kernel function interpolation.

The following coefficients must be defined for each pair of atom types via the \textit{pair_coeff} command as in the examples above.

- cutoff (distance units)

The \textit{mdpd} style computes the many-body interactions between mDPD particles following the formulations in \( (Li2013_POF) \). The dissipative and random forces are in the form same as the classical DPD, but the conservative force is local density dependent, which are given by

\[ F_{ij}^C = Aw_c(r_{ij})e_{ij} + B(\rho_i + \rho_j)w_d(r_{ij})e_{ij} \]

\[ F_{ij}^D = -\gamma \omega_D(r_{ij})(e_{ij} \cdot v_{ij})e_{ij} \]

\[ F_{ij}^R = \sigma \omega_R(r_{ij})\xi_{ij} \Delta t^{-1/2} e_{ij} \]
where the first term in $F_C$ with a negative coefficient $A < 0$ stands for an attractive force within an interaction range $r_c$, and the second term with $B > 0$ is the density-dependent repulsive force within an interaction range $r_d$.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above.

- A (force units)
- B (force units)
- $\gamma$ (force/velocity units)
- cutoff_c (distance units)
- cutoff_d (distance units)

The `tdpd` style computes the pairwise interactions and chemical concentration fluxes for tDPD particles following the formulations in \cite{Li2015_JCP}. The time evolution of a tDPD particle is governed by the conservation of momentum and concentration given by

$$\frac{d^2 r_i}{dt^2} = F_i = \sum_{i \neq j} (F^C_{ij} + F^D_{ij} + F^R_{ij})$$

$$\frac{dC_i}{dt} = Q_i = \sum_{i \neq j} (Q^D_{ij} + Q^R_{ij}) + Q^S_i$$

where the three components of $F_i$ including the conservative force $F^C_{ij}$, dissipative force $F^D_{ij}$ and random force $F^R_{ij}$ are expressed as

$$F^C_{ij} = A \omega_C(r_{ij}) e_{ij}$$

$$F^D_{ij} = -\gamma \omega_D(r_{ij}) (e_{ij} \cdot v_{ij}) e_{ij}$$

$$F^R_{ij} = \sigma \omega_R(r_{ij}) \xi_{ij} \Delta t^{-1/2} e_{ij}$$

$$\omega_C(r) = 1 - r/r_c$$

$$\omega_D(r) = \omega_D^2(r) = (1 - r/r_c)^{power_f}$$

$$\sigma^2 = 2\gamma k_B T$$

The concentration flux between two tDPD particles includes the Fickian flux $Q^D_{ij}$ and random flux $Q^R_{ij}$, which are given by

$$Q^D_{ij} = -\kappa_{ij} w_{DC}(r_{ij})(C_i - C_j)$$

$$Q^R_{ij} = \epsilon_{ij} (C_i + C_j) w_{RC}(r_{ij}) \xi_{ij}$$

$$w_{DC}(r_{ij}) = w_{DC}^2(r_{ij}) = (1 - r/r_{cc})^{power_{cc}}$$

$$\epsilon_{ij}^2 = m_s^2 \kappa_{ij} \rho$$

where the parameters kappa and epsilon determine the strength of the Fickian and random fluxes. $m_s$ is the mass of a single solute molecule. In general, $m_s$ is much smaller than the mass of a tDPD particle $m$. For more details, see \cite{Li2015_JCP}.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above.

- A (force units)
- $\gamma$ (force/velocity units)
- power_f (positive real)
- cutoff (distance units)
- cutoff_CC (distance units)
- $\kappa_i$ (diffusivity units)
- $\epsilon_i$ (diffusivity units)
- power_cc_i (positive real)

The last 3 values must be repeated $N_{species}$ times, so that values for each of the $N_{species}$ chemical species are specified, as indicated by the “I” suffix. In the first pair_coeff example above for pair_style tdpd, $N_{species} = 1$. In the second example, $N_{species} = 2$, so 3 additional coeffs are specified (for species 2).

**Example scripts**

There are example scripts for using all these pair styles in examples/USER/meso. The example for an eDPD simulation models heat conduction with source terms analog of periodic Poiseuille flow problem. The setup follows Fig.12 in (Li2014_JCP). The output of the short eDPD simulation (about 2 minutes on a single core) gives a temperature and density profiles as

![Graphs showing temperature and density profiles](image)

The example for a mDPD simulation models the oscillations of a liquid droplet started from a liquid film. The mDPD parameters are adopted from (Li2013_POF). The short mDPD run (about 2 minutes on a single core) generates a particle trajectory which can be visualized as follows.

![Particle trajectory](image)
The first image is the initial state of the simulation. If you click it a GIF movie should play in your browser. The second image is the final state of the simulation.

The example for a tDPD simulation computes the effective diffusion coefficient of a tDPD system using a method analogous to the periodic Poiseuille flow. The tDPD system is specified with two chemical species, and the setup follows Fig.1 in (Li2015_JCP). The output of the short tDPD simulation (about one and a half minutes on a single core) gives the concentration profiles of the two chemical species as

![Concentration Profiles](image)

**Mixing, shift, table, tail correction, restart, rRESPA info:**

The styles edpd, mdpd, mdpd/rhosum and tdpd do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

The styles edpd, mdpd, mdpd/rhosum and tdpd do not support the `pair_modify` shift, table, and tail options.

The styles edpd, mdpd, mdpd/rhosum and tdpd do not write information to binary restart files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.
18.326.4 Restrictions

The pair styles \textit{edpd}, \textit{mdpd}, \textit{mdpd/rhosum} and \textit{tdpd} are part of the USER-MESODPD package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

18.326.5 Related commands

Default: none

\begin{itemize}
\item \textit{cut} = the cutoff distance
\item \textit{table\_path} = the path to the potential table
\item \textit{BendingMode} = the parameter defining the type of the bending potential for nanotubes: 0 - harmonic bending (Srivastava), 1 - anharmonic potential of bending and bending-buckling (Zhigilei1)
\item \textit{TPMType} = the parameter determining the type of the inter-tube interaction term: 0 - segment-segment approach, 1 - segment-chain approach (Zhigilei2, Zhigilei3)
\end{itemize}

The segment-segment approach is approximately 5 times slower than segment-chain approximation. The parameter BendingMode also affects the calculation of the inter-tube interaction term when TPMType = 1. In this case, when BendingMode = 1, each continuous chain of segments is additionally replaced by a number of sub-chains divided by bending buckling kinks.

18.327.2 Examples

\begin{verbatim}
pair\_style mesont/tpm 30.0 MESONT-TABTP_10_10.xrs 0 0
\end{verbatim}
18.327.3 Description

The tubular potential model (TPM) force field is designed for mesoscopic simulations of interacting flexible nanotubes. The force field is based on the mesoscopic computational model suggested in Ref. (Srivastava). In this model, each nanotube is represented by a chain of mesoscopic elements in the form of stretchable cylindrical segments, where each segment consists of multiple atoms. Each nanotube is divided into segments by a sequence of nodes placed on the nanotube centerline. This sequence of nodes determines the spatial position of the cylindrical segments and defines the configuration of the entire tube.

The potential force field that controls the dynamic behavior of a system of interacting nanotubes is given by the following equation defining the potential energy of the system:

\[
U = U_{str} + U_{bnd} + U_{vdW}
\]

where \(U_{str}\) is the harmonic potential describing the stretching of nanotube (Srivastava), \(U_{bnd}\) is the potential for nanotube bending (Srivastava) and bending-buckling (Zhigilei1), and \(U_{vdW}\) is the potential describing van-der Waals interaction between nanotubes (Zhigilei2, Zhigilei3). The stretching energy, \(U_{str}\), is given by the sum of stretching energies of individual nanotube segments. The bending energy, \(U_{bnd}\), is given by the sum of bending energies in all internal nanotube nodes. The tube-tube interaction energy, \(U_{vdW}\), is calculated based on the tubular potential method suggested in Ref. (Zhigilei2). The tubular potential method is briefly described below.

The interaction between two straight nanotubes of arbitrary length and orientation is described by the approximate tubular potential developed in (Zhigilei3). This potential approximates the results of direct integration of carbon-carbon interatomic potential over the surfaces of the interacting nanotubes, with the force sources homogeneously distributed over the nanotube surfaces. The input data for calculation of tubular potentials are partially tabulated. For single-walled CNTs of arbitrary chirality, the tabulated potential data can be generated in the form of ASCII files TPSSTP.xrs and TPMA.xrs by the stand-alone code TMDPotGen included in the tool directory of LAMMPS release. The potential provided with LAMMPS release, MESONT-TABTP_10_10.xrs, is tabulated for (10,10) nanotubes.

Calculations of the interaction between curved or bent nanotubes are performed on either segment-segment or segment-chain basis. In the first case, activated when parameter TPMType is equal to 0, the tubular potential is calculated for each pair of interacting mesoscopic segments. In this case, however, small potential barriers for inter-tube sliding are introduced. While relatively small, these barriers are still larger than the ones that originate from the atomic-scale corrugation in atomistic modeling of inter-tube interaction. The latter are too weak to prevent room-temperature rearrangements of defect-free CNT, while the artificial mesoscopic barriers due to the segment-segment interaction can impede sliding of nanotubes with respect to each other and affect the kinetics of structural rearrangements in a system of nanotubes at moderate mesoscopic temperatures. In the second case, activated when parameter TPMType is equal to 1, the inter-tube interaction term is calculated based on the segment-chain approach. In this case, for each NT segment, the list of its neighboring segments is divided into short continuous chains of segments belonging to individual nanotubes. For each pair of a segment and a chain, the curved chain is approximated by a straight equivalent nanotube based on the weighted approach suggested in Ref. (Zhigilei2). Finally, the interaction between the segment and straight equivalent chain is calculated based on the tubular potential. In this case, and in the absence of bending buckling (i.e., when parameter BendingMode is equal to 0), the tubular potential method ensures the absence of corrugation of the effective inter-tube interaction potential for curved nanotubes and eliminates any barriers for the inter-tube sliding. As a result, the tubular potential method can describe the spontaneous self-assembly of nanotubes into continuous networks of bundles (Zhigilei1, Zhigilei3).

The TMD force field has been used for generation of nanotube films, fibers, and vertically aligned forests of nanotubes. Mesoscopic dynamic simulations were used to prepare realistic structures of continuous networks of nanotube bundles and to study their structural and mechanical properties (Zhigilei1, Zhigilei3, Zhigilei4, Zhigilei5, Zhigilei6). With additional models for heat transfer, this force filed was also used to study the thermal transport properties of carbon nanotube films (Zhigilei7, Zhigilei8, Zhigilei8). The methods for modeling of the mechanical energy dissipation into heat (energy exchange between the dynamic degrees of freedom of the mesoscopic model and the energy of atomic
vibrations that are not explicitly represented in the model) (Zhigilei10) and mesoscopic description of covalent cross-links between nanotubes (Banna) have also been developed but are not included in this first release of the LAMMPS implementation of the force field. Further details can be found in references provided below.

The MESONT package also provides TMDGen code designed to generate initial samples composed of straight and dispersed nanotubes of given chirality and length at a given material density, which is available in tools directory. In the generated samples, nanotubes are distributed with random positions and orientations. Both periodic and free boundary conditions are available along each axis of the system of coordinates. All parameters in the sample files generated with TMDGen are given in metal units.

18.327.4 Restrictions

This pair style is a part of the USER-MSEONT package, and it is only enabled if LAMMPS is built with that package. See the Build package doc page for more information.

This pair potential requires use of mesont atomic style.

This pair potential requires the newton setting to be “on” for pair interactions.

The cutoff distance should be set to be at least \( \max \left[ 2L, \sqrt{L^2/2 + (2R + T_{cut})^2} \right] \), where \( L \) is the maximum segment length, \( R \) is the maximum tube radius, and \( T_{cut} = 10.2 \) Å is the maximum distance between the surfaces of interacting segments. Because of the use of extended chain concept at CNT ends, the recommended cutoff is 3L.

The MESONT-TABTP_10_10.xrs potential file provided with LAMMPS (see the potentials directory) is parameterized for metal units. You can use the carbon nanotube mesoscopic force field with any LAMMPS units, but you would need to create your own TPMSSTP.xrs and TPMA.xrs potential files with coefficients listed in appropriate units, if your simulation does not use “metal” units.

The chirality parameters set during system generation must match the values specified during generation of the potential tables.

18.328.3 Description

Within DFT quantum mechanics, generalized pseudopotential theory (GPT) (Moriarty) provides a first-principles approach to multi-ion interatomic potentials in d-band transition metals, with a volume-dependent, real-space total-energy functional for the N-ion elemental bulk material in the form

\[
E_{tot}(\mathbf{R}_1 \ldots \mathbf{R}_N) = NE_{\text{vol}}(\Omega) + \frac{1}{2} \sum_{i,j} \, v_2(ij; \Omega) + \frac{1}{6} \sum_{i,j,k} \, v_3(ijk; \Omega) + \frac{1}{24} \sum_{i,j,k,l} \, v_4(ijkl; \Omega)
\]

where the prime on each summation sign indicates the exclusion of all self-interaction terms from the summation. The leading volume term \(E_{\text{vol}}\) as well as the two-ion central-force pair potential \(v_2\) and the three- and four-ion angular-force potentials, \(v_3\) and \(v_4\), depend explicitly on the atomic volume \(\Omega\), but are structure independent and transferable to all bulk ion configurations, either ordered or disordered, and with or without the presence of point and line defects. The simplified model GPT or MGPT (Moriarty2, Moriarty3), which retains the form of \(E_{tot}\) and permits more efficient large-scale atomistic simulations, derives from the GPT through a series of systematic approximations applied to \(E_{\text{vol}}\) and the potentials \(v_n\) that are valid for mid-period transition metals with nearly half-filled d bands.

Both analytic (Moriarty2) and matrix (Moriarty3) representations of MGPT have been developed. In the more general matrix representation, which can also be applied to f-band actinide metals and permits both canonical and non-canonical d/f bands, the multi-ion potentials are evaluated on the fly during a simulation through d- or f-state matrix multiplication, and the forces that move the ions are determined analytically. Fast matrix-MGPT algorithms have been developed independently by Gosli (Gosli, Moriarty3) and by Oppelstrup (Oppelstrup).

The `mgpt` pair style calculates forces, energies, and the total energy per atom, \(E_{tot}/N\), using the Oppelstrup matrix-MGPT algorithm. Input potential and control data are entered through the `pair_coeff` command. Each material treated requires input parmin and potin potential files, as shown in the above examples, as well as specification by the user of the initial atomic volume \(\Omega\) through `pair_coeff`. At the beginning of a time step in any simulation, the total volume of the simulation cell \(V\) should always be equal to \(\Omega \times N\), where \(N\) is the number of metal ions present, taking into account the presence of any vacancies and/or interstitials in the case of a solid. In a constant-volume simulation, which is the normal mode of operation for the `mgpt` pair style, \(\Omega\) and \(N\) all remain constant throughout the simulation and thus are equal to their initial values. In a constant-stress simulation, the cell volume \(V\) will change (slowly) as the simulation proceeds. After each time step, the atomic volume should be updated by the code as \(\Omega = V/N\). In addition, the volume term \(E_{\text{vol}}\) and the potentials \(v_2, v_3\) and \(v_4\) have to be removed at the end of the time step, and then respecified at the new value of \(\Omega\). In all simulations, \(\Omega\) must remain within the defined volume range for \(E_{\text{vol}}\) and the potentials for the given material.

The default option `volpress yes` in the `pair_coeff` command includes all volume derivatives of \(E_{tot}\) required to calculate the stress tensor and pressure correctly. The option `volpress no` disregards the pressure contribution resulting from
the volume term E_vol, and can be used for testing and analysis purposes. The additional optional variable nbody controls the specific terms in E_tot that are calculated. The default option and the normal option for mid-period transition and actinide metals is nbody 1234 for which all four terms in E_tot are retained. The option nbody 12, for example, retains only the volume term and the two-ion pair potential term and can be used for GPT series-end transition metals that can be well described without v_3 and v_4. The nbody option can also be used to test or analyze the contribution of any of the four terms in E_tot to a given calculated property.

The mgpt pair style makes extensive use of matrix algebra and includes optimized kernels for the BlueGene/Q architecture and the Intel/AMD (x86) architectures. When compiled with the appropriate compiler and compiler switches (-msse3 on x86, and using the IBM XL compiler on BG/Q), these optimized routines are used automatically. For BG/Q machines, building with the default Makefile for that architecture (e.g., “make bgq”) should enable the optimized algebra routines. For x-86 machines, there is a provided Makefile.mgptfast which enables the fast algebra routines, i.e. build LAMMPS with “make mgptfast”. The user will be informed in the output files of the matrix kernels in use. To further improve speed, on x86 the option precision single can be added to the pair_coeff command line, which improves speed (up to a factor of two) at the cost of doing matrix calculations with 7 digit precision instead of the default 16. For consistency the default option can be specified explicitly by the option precision double.

All remaining potential and control data are contained with the parmin and potin files, including cutoffs, atomic mass, and other basic MGPT variables. Specific MGPT potential data for the transition metals tantalum (Ta4 and Ta6.8x potentials), molybdenum (Mo5.2 potentials), and vanadium (V6.1 potentials) are contained in the LAMMPS potentials directory. The stored files are, respectively, Ta4.mgpt.parmin, Ta4.mgpt.potin, Ta6.8x.mgpt.parmin, Ta6.8x.mgpt.potin, Mo5.2.mgpt.parmin, Mo5.2.mgpt.potin, V6.1.mgpt.parmin, and V6.1.mgpt.potin. Useful corresponding informational “README” files on the Ta4, Ta6.8x, Mo5.2 and V6.1 potentials are also included in the potentials directory. These latter files indicate the volume mesh and range for each potential and give appropriate references for the potentials. It is expected that MGPT potentials for additional materials will be added over time.

Useful example MGPT scripts are given in the examples/USER/mgpt directory. These scripts show the necessary steps to perform constant-volume calculations and simulations. It is strongly recommended that the user work through and understand these examples before proceeding to more complex simulations.

Note: For good performance, LAMMPS should be built with the compiler flags “-O3 -msse3 -funroll-loops” when including this pair style. The src/MAKE/OPTIONS/Makefile.mgptfast is an example machine Makefile with these options included as part of a standard MPI build. Note that it as provided, it will build with whatever low-level compiler (g++, icc, etc) is the default for your MPI installation.

Mixing, shift, table tail correction, restart:

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.
18.328.4 Restrictions

This pair style is part of the USER-MGPT package and is only enabled if LAMMPS is built with that package. See the build package doc page for more info.

The MGPT potentials require the newton setting to be “on” for pair style interactions.

The stored parmin and potin potential files provided with LAMMPS in the “potentials” directory are written in Rydberg atomic units, with energies in Rydbergs and distances in Bohr radii. The mgpt pair style converts Rydbergs to Hartrees to make the potential files compatible with LAMMPS electron units.

The form of E_tot used in the mgpt pair style is only appropriate for elemental bulk solids and liquids. This includes solids with point and extended defects such as vacancies, interstitials, grain boundaries and dislocations. Alloys and free surfaces, however, require significant modifications, which are not included in the mgpt pair style. Likewise, the hybrid pair style is not allowed, where MGPT would be used for some atoms but not for others.

Electron-thermal effects are not included in the standard MGPT potentials provided in the “potentials” directory, where the potentials have been constructed at zero electron temperature. Physically, electron-thermal effects may be important in 3d (e.g., V) and 4d (e.g., Mo) transition metals at high temperatures near melt and above. It is expected that temperature-dependent MGPT potentials for such cases will be added over time.

18.328.5 Related commands

pair_coeff

18.328.6 Default

The options defaults for the pair_coeff command are volpress yes, nbody 1234, and precision double.

18.329 pair_style mie/cut command

18.330 pair_style mie/cut/gpu command

18.330.1 Syntax

pair_style mie/cut cutoff

- cutoff = global cutoff for mie/cut interactions (distance units)
18.330.2 Examples

```
pair_style mie/cut 10.0
pair_coeff 1 1 0.72 3.40 23.00 6.66
pair_coeff 2 2 0.30 3.55 12.65 6.00
pair_coeff 1 2 0.46 3.32 16.90 6.31
```

18.330.3 Description

The `mie/cut` style computes the Mie potential, given by

\[
E = C \epsilon \left( \left( \frac{\sigma}{r} \right)^{\gamma_{\text{rep}}} - \left( \frac{\sigma}{r} \right)^{\gamma_{\text{att}}} \right) \quad r < r_c
\]

Rc is the cutoff and C is a function that depends on the repulsive and attractive exponents, given by:

\[
C = \left( \frac{\gamma_{\text{rep}}}{\gamma_{\text{rep}} - \gamma_{\text{att}}} \right) \left( \frac{\gamma_{\text{rep}}}{\gamma_{\text{att}}} \right)^{\gamma_{\text{att}}(\frac{\gamma_{\text{rep}}}{\gamma_{\text{att}}})}
\]

Note that for 12/6 exponents, C is equal to 4 and the formula is the same as the standard Lennard-Jones potential.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- epsilon (energy units)
- sigma (distance units)
- gammaR
- gammaA
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I != J, the epsilon and sigma coefficients and cutoff distance for all of the mie/cut pair styles can be mixed. If not explicitly defined, both the repulsive and attractive gamma exponents for different atoms will be calculated following the same mixing rule defined for distances. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the `pair_modify` shift option for the energy of the pair interaction.

This pair style supports the `pair_modify` tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to `binary restart files`, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the `inner`, `middle`, and `outer` keywords of the `run_style respa` command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the `run_style` command for details.
18.330.4 Restrictions

(Mie) G. Mie, Ann Phys, 316, 657 (1903).

18.331 pair_style mliap command

18.331.1 Syntax

pair_style mliap

18.331.2 Examples

pair_style mliap model linear InP.mliap.model descriptor sna InP.mliap.descriptor
pair_style mliap model quadratic W.mliap.model descriptor sna W.mliap.descriptor
pair_coeff * * In P

18.331.3 Description

Pair style mliap provides a general interface to families of machine-learning interatomic potentials. It provides separate definitions of the interatomic potential functional form (model) and the geometric quantities that characterize the atomic positions (descriptor). By defining model and descriptor separately, it is possible to use many different models with a given descriptor, or many different descriptors with a given model. Currently, the pair_style supports just two models, linear and quadratic, and one descriptor, sna, the SNAP descriptor used by pair_style snap, including the linear, quadratic, and chem variants. Work is currently underway to extend the interface to handle neural network energy models, and it is also straightforward to add new descriptor styles.

The pair_style mliap command must be followed by two keywords model and descriptor in either order. A single pair_coeff command is also required. The first 2 arguments must be ** so as to span all LAMMPS atom types. This is followed by a list of N arguments that specify the mapping of MLIAP element names to LAMMPS atom types, where N is the number of LAMMPS atom types.

The model keyword is followed by a model style, currently limited to either linear or quadratic. In both cases, this is followed by a single argument specifying the model filename containing the linear or quadratic coefficients for a set of elements. The model filename usually ends in the .mliap.model extension. It may contain coefficients for many elements. The only requirement is that it contain at least those element names appearing in the pair_coeff command.

The top of the model file can contain any number of blank and comment lines (start with #), but follows a strict format after that. The first non-blank non-comment line must contain two integers:
• nelems = Number of elements
• ncoeff = Number of coefficients

This is followed by one block for each of the nelem elements. Each block consists of ncoeff coefficients, one per line. Note that this format is similar, but not identical to that used for the pair_style snap coefficient file. Specifically, the line containing the element weight and radius is omitted, since these are handled by the descriptor.

The descriptor keyword is followed by a descriptor style, and additional arguments. Currently the only descriptor style is sna, indicating the bispectrum component descriptors used by the Spectral Neighbor Analysis Potential (SNAP) potentials of pair_style snap. The 'p' in SNAP is dropped, because keywords that match pair_styles are silently stripped out by the LAMMPS command parser. A single additional argument specifies the descriptor filename containing the parameters and settings used by the SNAP descriptor. The descriptor filename usually ends in the .mliap.descriptor extension.

The SNAP descriptor file closely follows the format of the pair_style snap parameter file. The file can contain blank and comment lines (start with #) anywhere. Each non-blank non-comment line must contain one keyword/value pair. The required keywords are rcutfac and twojmax. There are many optional keywords that are described on the pair_style snap doc page. In addition, the SNAP descriptor file must contain the nelems, elems, radelems, and welems keywords. The nelems keyword specifies the number of elements provided in the other three keywords. The elems keyword is followed by a list of nelems element names that must include the element names appearing in the pair_coeff command, but can contain other names too. Similarly, the radelems and welems keywords are followed by lists of nelems numbers giving the element radius and element weight of each element. Obviously, the order in which the elements are listed must be consistent for all three keywords.

See the pair_coeff doc page for alternate ways to specify the path for these model and descriptor files.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a pair_coeff command with I != J arguments for this style.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.331.4 Restrictions

This style is part of the MLIAP package. It is only enabled if LAMMPS was built with that package. In addition, building LAMMPS with the MLIAP package requires building LAMMPS with the SNAP package. See the Build package doc page for more info.
18.331.5 Related commands

pair_style snap.

Default: none

18.332 pair_style mm3/switch3/coulgauss/long command

18.332.1 Syntax

```
pair_style style args
```

- **style** = mm3/switch3/coulgauss/long
- **args** = list of arguments for a particular style

```
mm3/switch3/coulgauss/long args = cutoff (cutoff2) width
  cutoff = global cutoff for MM3 (and Coulombic if only 1 arg) (distance units)
  cutoff2 = global cutoff for Coulombic (optional) (distance units)
  width = width parameter of the smoothing function (distance units)
```

18.332.2 Examples

```
pair_style mm3/switch3/coulgauss/long 12.0 3.0
pair_coeff 1 0.2 2.5 1.2

pair_style mm3/switch3/coulgauss/long 12.0 10.0 3.0
pair_coeff 1 0.2 2.5 1.2
```

18.332.3 Description

The `mm3/switch3/coulgauss/long` style evaluates the MM3 vdW potential (Allinger)

\[
E = \epsilon_{ij} \left[ -2.25 \left( \frac{r_{v,ij}}{r_{ij}} \right)^6 + 1.84(10)^3 \exp\left[-12.0r_{ij}/r_{v,ij}\right] \right] S_3(r_{ij})
\]

\[
r_{v,ij} = r_{v,i} + r_{v,j}
\]

\[
\epsilon_{ij} = \sqrt{\epsilon_i \epsilon_j}
\]

, which goes smoothly to zero at the cutoff \( r_c \) as defined by the switching function

\[
S_3(r) = \begin{cases} 
1 & \text{if } r < r_c - w \\
3x^2 - 2x^3 & \text{if } r < r_c \text{ with } x = \frac{r - r_c}{w} \\
0 & \text{if } r \geq r_c
\end{cases}
\]

where \( w \) is the width defined in the arguments. This potential is combined with Coulomb interaction between Gaussian charge densities:

\[
E = \frac{q_i q_j \text{erf} \left( r/\sqrt{\gamma_1^2 + \gamma_2^2} \right)}{\epsilon r_{ij}}
\]
where $q_i$ and $q_j$ are the charges on the 2 atoms, epsilon is the dielectric constant which can be set by the *dielectric* command. \( \gamma_i \) and \( \gamma_j \) are the widths of the Gaussian charge distribution and erf() is the error-function. This style has to be used in conjunction with the *kspace_style* command.

If one cutoff is specified it is used for both the vdW and Coulomb terms. If two cutoffs are specified, the first is used as the cutoff for the vdW terms, and the second is the cutoff for the Coulombic term.

The following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( \epsilon \) (energy)
- \( r_v \) (distance)
- \( \gamma \) (distance)

Mixing, shift, table, tail correction, restart, rRESPA info:

Mixing rules are fixed for this style as defined above.

Shifting the potential energy is not necessary because the switching function ensures that the potential is zero at the cut-off.

### 18.332.4 Restrictions

These styles are part of the USER-YAFF package. They are only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

### 18.332.5 Related commands

**pair_coeff**

Default: none

### 18.333 pair_style momb command

#### 18.333.1 Syntax

```
pair_style momb cutoff s6 d
```

- cutoff = global cutoff (distance units)
- s6 = global scaling factor of the exchange-correlation functional used (unitless)
- d = damping scaling factor of Grimme’s method (unitless)
18.333.2 Examples

```plaintext
pair_style momb 12.0 0.75 20.0
pair_style hybrid/overlay eam/fs lj/charmm/coul/long 10.0 12.0 momb 12.0 0.75 20.0
  → morse 5.5
pair_coeff 1 2 momb 0.0 1.0 1.0 10.2847 2.361
```

18.333.3 Description

Style *momb* computes pairwise van der Waals (vdW) and short-range interactions using the Morse potential and (Grimme) method implemented in the Many-Body Metal-Organic (MOMB) force field described comprehensively in (Fichthorn) and (Zhou). Grimme’s method is widely used to correct for dispersion in density functional theory calculations.

\[ E = D_0 \left[ \exp^{-2\alpha(r-r_0)} - 2 \exp^{-\alpha(r-r_0)} \right] - s_6 \frac{C_6}{r_0^6} f_{damp}(r, R_r) \]

\[ f_{damp}(r, R_r) = \frac{1}{1 + \exp^{-d(r/R_r - 1)}} \]

For the *momb* pair style, the following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* as described below:

- \( D_0 \) (energy units)
- \( \alpha \) (1/distance units)
- \( r_0 \) (distance units)
- \( C_6 \) (energy*distance^6 units)
- \( R_r \) (distance units, typically sum of atomic vdW radii)

18.333.4 Restrictions

This style is part of the USER-MISC package. It is only enabled if LAMMPS is built with that package. See the Build package doc page on for more info.

18.333.5 Related commands

*pair_coeff*, *pair_style* morse

18.335 pair_style morse/gpu command

18.336 pair_style morse/omp command

18.337 pair_style morse/opt command

18.338 pair_style morse/smooth/linear command

18.339 pair_style morse/smooth/linear/omp command

18.340 pair_style morse/kk command

18.340.1 Syntax

\texttt{pair\_style} style args

- style = morse or morse/smooth/linear or morse/soft
- args = list of arguments for a particular style

\texttt{morse} args = cutoff
  - cutoff = global cutoff for Morse interactions (distance units)

\texttt{morse/smooth/linear} args = cutoff
  - cutoff = global cutoff for Morse interactions (distance units)

18.340.2 Examples

\begin{verbatim}
pair_style morse 2.5
pair_style morse/smooth/linear 2.5
pair_coeff * * 100.0 2.0 1.5
pair_coeff 1 1 100.0 2.0 1.5 3.0
\end{verbatim}

18.340.3 Description

Style \textit{morse} computes pairwise interactions with the formula

\[ E = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c \]

Rc is the cutoff.

The following coefficients must be defined for each pair of atoms types via the \texttt{pair\_coeff} command as in the examples above, or in the data file or restart files read by the \texttt{read\_data} or \texttt{read\_restart} commands:

- \( D_0 \) (energy units)
- \( \alpha \) (1/distance units)
LAMMPS Documentation

- \( r_0 \) (distance units)
- \( \text{cutoff} \) (distance units)

The last coefficient is optional. If not specified, the global morse cutoff is used.

The \textit{morse/smooth/linear} variant is similar to the \textit{lj/smooth/linear} variant in that it adds to the potential a shift and a linear term so that both, potential energy and force, go to zero at the cut-off:

\[
\phi(r) = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c
\]

\[
E(r) = \phi(r) - \phi(R_c) - (r - R_c) \left. \frac{d\phi}{dr} \right|_{r=R_c} \quad r < R_c
\]

The syntax of the \texttt{pair_style} and \texttt{pair_coeff} commands are the same for the \textit{morse} and \textit{morse/smooth/linear} styles.

A version of the \textit{morse} style with a soft core, \textit{morse/soft}, suitable for use in free energy calculations, is part of the USER-FEP package and is documented with the \texttt{pair_style */soft} styles. The version with soft core is only available if LAMMPS was built with that package. See the \texttt{Build package} doc page for more info.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \texttt{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

\textbf{Mixing, shift, table, tail correction, restart, rRESPA info:}

None of these pair styles support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

All of these pair styles support the \texttt{pair_modify} shift option for the energy of the pair interaction.

The \texttt{pair_modify} table options is not relevant for the Morse pair styles.

None of these pair styles support the \texttt{pair_modify} tail option for adding long-range tail corrections to energy and pressure.

All of these pair styles write their information to \texttt{binary restart files}, so \texttt{pair_style} and \texttt{pair_coeff} commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the \texttt{pair} keyword of the \texttt{run_style respa} command. They do not support the \texttt{inner}, \texttt{middle}, \texttt{outer} keywords.
18.340.4 Restrictions

The \textit{morse/smooth/linear} pair style is only enabled if LAMMPS was built with the USER-MISC package. See the \textit{Build package} doc page for more info.

18.340.5 Related commands

\texttt{pair_coeff}, \texttt{pair_style */soft}

\textbf{Default:} none

18.341 \texttt{pair_style multi/lucy} command

18.341.1 Syntax

\begin{verbatim}
pair_style multi/lucy style N keyword ...

- style = \textit{lookup} or \textit{linear} = method of interpolation
- N = use N values in \textit{lookup}, \textit{linear} tables
\end{verbatim}

18.341.2 Examples

\begin{verbatim}
pair_style multi/lucy linear 1000
pair_coeff * * multibody.table ENTRY1 7.0
\end{verbatim}

18.341.3 Description

Style \textit{multi/lucy} computes a density-dependent force following from the many-body form described in \textit{(Moore)} and \textit{(Warren)} as

\[ F_{i}^{DD}(\rho_{i}, \rho_{j}, r_{ij}) = \frac{1}{2} \omega_{DD}(r_{ij}) [A(\rho_{i}) + A(\rho_{j})] e_{ij} \]

which consists of a density-dependent function, \(A(\rho)\), and a radial-dependent weight function, \(\omega_{DD}(r_{ij})\). The radial-dependent weight function, \(\omega_{DD}(r_{ij})\), is taken as the Lucy function:

\[ \omega_{DD}(r_{ij}) = \left(1 + \frac{3r_{ij}}{r_{cut}}\right) \left(1 + \frac{r_{ij}}{r_{cut}}\right)^{3} \]

The density-dependent energy for a given particle is given by:

\[ u_{i}^{DD}(\rho_{i}) = \frac{\pi r_{cut}^{4}}{84} \int_{\rho_{i}}^{\rho_{i}} A(\rho') d\rho' \]

See the supporting information of \textit{(Brennan)} or the publication by \textit{(Moore)} for more details on the functional form.

An interpolation table is used to evaluate the density-dependent energy (\(\int A(\rho') d\rho'\)) and force (\(A(\rho')\)). Note that the pre-factor to the energy is computed after the interpolation, thus the \(\int A(\rho') d\rho'\) will have units of energy / length^4.

The interpolation table is created as a pre-computation by fitting cubic splines to the file values and interpolating the density-dependent energy and force at each of \(N\) densities. During a simulation, the tables are used to interpolate the
density-dependent energy and force as needed for each pair of particles separated by a distance $R$. The interpolation is done in one of 2 styles: \textit{lookup} and \textit{linear}.

For the \textit{lookup} style, the density is used to find the nearest table entry, which is the density-dependent energy and force.

For the \textit{linear} style, the density is used to find the 2 surrounding table values from which the density-dependent energy and force are computed by linear interpolation.

The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above.

- filename
- keyword
- cutoff (distance units)

The filename specifies a file containing the tabulated density-dependent energy and force. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

\begin{verbatim}
# Density-dependent function (one or more comment or blank lines)
DD-FUNCTION (keyword is first text on line)
N 500 R 1.0 10.0 (N, R, RSQ parameters)
(blank)
1 1.0 25.5 102.34 (index, density, energy/$r^4$, force)
2 1.02 23.4 98.5
...
500 10.0 0.001 0.003
\end{verbatim}

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the \textit{pair_coeff} command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the $N$ specified in the \textit{pair_style multi/lucy} command. Let $N_{\text{table}} = N$ in the \textit{pair_style} command, and $N_{\text{file}} = \text{“N”}$ in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the $N_{\text{file}}$ tabulated values as nodal points. It uses these to interpolate the density-dependent energy and force at $N_{\text{table}}$ different points. The resulting tables of length $N_{\text{table}}$ are then used as described above, when computing the density-dependent energy and force. This means that if you want the interpolation tables of length $N_{\text{table}}$ to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set $N_{\text{table}} = N_{\text{file}}$, and use the “RSQ” parameter. This is because the internal table abscissa is always $RSQ$ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in \textit{density} uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values $rlo$ and $rhi$. If specified, the density associated with each density-dependent energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The density values in the tabulated file are ignored in this case. For
“R”, distances uniformly spaced between \( rlo \) and \( rhi \) are computed; for “RSQ”, squared distances uniformly spaced between \( rlo*rlo \) and \( rhi*rhi \) are computed.

**Note:** If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the density value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning density-dependent energy and force values to a different density, which is probably not what you want. LAMMPS will warn if this is occurring.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in density units), the third value is the density-dependent function value (in energy units / length^4), and the fourth is the force (in force units). The density values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The `pair_modify` shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair_style multi/lucy” command to binary restart files, so a pair_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, pair_coeff commands do need to be specified in the restart input script.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

**18.341.4 Restrictions**

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

pair_coeff * * multibody.table ENTRY1 h2o 1fluid 7.0
```

18.343.3 Description

Style `multi/lucy/rx` is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of \( m \) species whose reaction rate kinetics are determined from a set of \( n \) reaction rate equations through the `fix rx` command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. Style `multi/lucy/rx` computes the site-site density-dependent force following from the many-body form described in (Moore) and (Warren) as

\[
F_{DD}^i(\rho_i, \rho_j, r_{ij}) = \frac{1}{2} \omega_{DD}(r_{ij}) [A(\rho_i) + A(\rho_j)] e_{ij}
\]

which consists of a density-dependent function, \( A(\rho) \), and a radial-dependent weight function, \( \omega_{DD}(r_{ij}) \). The radial-dependent weight function, \( \omega_{DD}(r_{ij}) \), is taken as the Lucy function:

\[
\omega_{DD}(r_{ij}) = \left(1 + \frac{3r_{ij}}{r_{cut}}\right) \left(1 + \frac{r_{ij}}{r_{cut}}\right)^3
\]

The density-dependent energy for a given particle is given by:

\[
u_{DD}^i(\rho_i) = \frac{\pi r_{cut}^4}{84} \int_{\rho_0}^{\rho_i} A(\rho') d\rho'
\]

See the supporting information of (Brennan) or the publication by (Moore) for more details on the functional form.

An interpolation table is used to evaluate the density-dependent energy (\( \int A(\rho')d\rho' \) and force (\( A(\rho') \)). Note that the pre-factor to the energy is computed after the interpolation, thus the \( \int A(\rho')d\rho' \) will have units of energy / length^4.

The interpolation table is created as a pre-computation by fitting cubic splines to the file values and interpolating the density-dependent energy and force at each of \( N \) densities. During a simulation, the tables are used to interpolate the density-dependent energy and force as needed for each pair of particles separated by a distance \( R \). The interpolation is done in one of 2 styles: `lookup` and `linear`. 
For the **lookup** style, the density is used to find the nearest table entry, which is the density-dependent energy and force.

For the **linear** style, the density is used to find the 2 surrounding table values from which the density-dependent energy and force are computed by linear interpolation.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above.

- filename
- keyword
- species1
- species2
- cutoff (distance units)

The filename specifies a file containing the tabulated density-dependent energy and force. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The species tags define the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the `fix rx` command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the `fractional` or `molecular` weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

```
# Density-dependent function (one or more comment or blank lines)

DD-FUNCTION (keyword is first text on line)
N 500 R 1.0 10.0 (N, R, RSQ parameters)
(blank)
1 1.0 25.5 102.34 (index, density, energy/r^4, force)
2 1.02 23.4 98.5
...
500 10.0 0.001 0.003
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the `pair_coeff` command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the $N$ specified in the `pair_style multi/lucy/rx` command. Let $N_{table}$ = $N$ in the pair_style command, and $N_{file}$ = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the $N_{file}$ tabulated values as nodal points. It uses these to interpolate the density-dependent energy and force at $N_{table}$ different points. The resulting tables of length $N_{table}$ are then used as described above, when computing the density-dependent energy and force. This means that if you want the interpolation tables of length $N_{table}$ to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set $N_{table}$ = $N_{file}$, and use the “RSQ” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.
All other parameters are optional. If “R” or “RSQ” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in density uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values rlo and rhi. If specified, the density associated with each density-dependent energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The density values in the table file are ignored in this case. For “R”, distances uniformly spaced between rlo and rhi are computed; for “RSQ”, squared distances uniformly spaced between rlo*rlo and rhi*rhi are computed.

**Note:** If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the density value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning density-dependent energy and force values to a different density, which is probably not what you want. LAMMPS will warn if this is occurring.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in density units), the third value is the density-dependent function value (in energy units / length^4), and the fourth is the force (in force units). The density values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The *pair_modify* shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair_style multi/lucy/rx” command to binary restart files, so a *pair_style* command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, *pair_coeff* commands do need to be specified in the restart input script.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner, middle, outer* keywords.

Styles with a *gpu, intel, kk, omp, or opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.
18.343.4 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.343.5 Related commands

pair_coeff

Default: fractional weighting

18.344 pair_style nb3b/harmonic command

18.344.1 Syntax

```
pair_style nb3b/harmonic
```

18.344.2 Examples

```
pair_style nb3b/harmonic
pair_coeff * * MgOH.nb3bharmonic Mg O H
```

18.344.3 Description

This pair style computes a non-bonded 3-body harmonic potential for the energy \( E \) of a system of atoms as

\[
E = K(\theta - \theta_0)^2
\]

where \( \theta_0 \) is the equilibrium value of the angle and \( K \) is a prefactor. Note that the usual \( 1/2 \) factor is included in \( K \). The form of the potential is identical to that used in angle_style harmonic, but in this case, the atoms do not need to be explicitly bonded.

Only a single pair_coeff command is used with this style which specifies a potential file with parameters for specified elements. These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:

- filename
- \( N \) element names = mapping of elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.nb3b.harmonic has potential values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:
The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the potential file. The final C argument maps LAMMPS atom type 4 to the C element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when the potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials. An example of a pair_coeff command for use with the hybrid pair style is:

```
pair_coeff * * nb3b/harmonic MgOH.nb3b.harmonic Mg O H
```

Three-body non-bonded harmonic files in the potentials directory of the LAMMPS distribution have a “.nb3b.harmonic” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements.

Each entry has six arguments. The first three are atom types as referenced in the LAMMPS input file. The first argument specifies the central atom. The fourth argument indicates the $K$ parameter. The fifth argument indicates $\theta_0$. The sixth argument indicates a separation cutoff in Angstroms.

For a given entry, if the second and third arguments are identical, then the entry is for a cutoff for the distance between types 1 and 2 (values for $K$ and $\theta_0$ are irrelevant in this case).

For a given entry, if the first three arguments are all different, then the entry is for the $K$ and $\theta_0$ parameters (the cutoff in this case is irrelevant).

It is required that the potential file contains entries for all permutations of the elements listed in the pair_coeff command. If certain combinations are not parameterized the corresponding parameters should be set to zero. The potential file can also contain entries for additional elements which are not used in a particular simulation; LAMMPS ignores those entries.

### 18.344.4 Restrictions

This pair style can only be used if LAMMPS was built with the MANYBODY package. See the Build package doc page for more info.

pair_style nm/cut/coul/long 12.0 15.0
pair_coeff * * 0.01 5.4 8.0 7.0
pair_coeff 1 1 0.01 4.4 7.0 6.0
```
18.350.3 Description

Style *nm* computes site-site interactions based on the N-M potential by Clarke, mainly used for ionic liquids. A site can represent a single atom or a united-atom site. The energy of an interaction has the following form:

\[ E = \frac{E_0}{(n - m)} \left[ m \left( \frac{r_0}{r} \right)^n - n \left( \frac{r_0}{r} \right)^m \right] \quad r < r_c \]

where \( r_c \) is the cutoff.

Style *nm/cut/coul/cut* adds a Coulombic pairwise interaction given by

\[ E = \frac{C q_i q_j}{\epsilon r} \quad r < r_c \]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, and \( \epsilon \) is the dielectric constant which can be set by the *dielectric* command. If one cutoff is specified in the pair_style command, it is used for both the N-M and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the N-M and Coulombic terms respectively.

Styles *nm/cut/coul/long* compute the same Coulombic interactions as style *nm/cut/coul/cut* except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the *kspace_style* command and its *ewald* or *pppm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

For all of the *nm* pair styles, the following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands.

- \( E_0 \) (energy units)
- \( r_0 \) (distance units)
- \( n \) (unitless)
- \( m \) (unitless)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global N-M and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both N-M and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the N-M and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style *nm*, since it has no Coulombic terms.

For *nm/cut/coul/long* only the N-M cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

These pair styles do not support mixing. Thus, coefficients for all LJ pairs must be specified explicitly.

All of the *nm* pair styles supports the *pair_modify* shift option for the energy of the pair interaction.

The *nm/cut/coul/long* pair styles support the *pair_modify* table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the *nm* pair styles support the *pair_modify* tail option for adding a long-range tail correction to the energy and pressure for the N-M portion of the pair interaction.

All of the *nm* pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.
All of the \textit{nm} pair styles can only be used via the \textit{pair} keyword of the \textit{run_style respa} command. They do not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix command-line switch} when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

### 18.350.4 Restrictions

These pair styles are part of the MISC package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

### 18.350.5 Related commands

\textit{pair_coeff}

\textbf{Default: none}

### 18.351 \textit{pair_style none} command

#### 18.351.1 Syntax

\begin{verbatim}
pair_style none
\end{verbatim}

#### 18.351.2 Examples

\begin{verbatim}
pair_style none
\end{verbatim}
18.351.3 Description

Using a pair style of none means pair forces and energies are not computed. With this choice, the force cutoff is 0.0, which means that only atoms within the neighbor skin distance (see the neighbor command) are communicated between processors. You must insure the skin distance is large enough to acquire atoms needed for computing bonds, angles, etc.

A pair style of none will also prevent pairwise neighbor lists from being built. However if the neighbor style is bin, data structures for binning are still allocated. If the neighbor skin distance is small, then these data structures can consume a large amount of memory. So you should either set the neighbor style to nsq or set the skin distance to a larger value.

See the pair_style zero for a way to trigger the building of a neighbor lists, but compute no pairwise interactions.

\begin{verbatim}
18.356.3 Description

The \texttt{oxdna} pair styles compute the pairwise-additive parts of the oxDNA force field for coarse-grained modelling of DNA. The effective interaction between the nucleotides consists of potentials for the excluded volume interaction \texttt{oxdna/excv}, the stacking \texttt{oxdna/stk}, cross-stacking \texttt{oxdna/xstk} and coaxial stacking interaction \texttt{oxdna/coaxstk} as well as the hydrogen-bonding interaction \texttt{oxdna/hbond} between complementary pairs of nucleotides on opposite strands. Average sequence or sequence-dependent stacking and base-pairing strengths are supported (Sulc). Quasi-unique base-pairing between nucleotides can be achieved by using more complementary pairs of atom types like 5-8 and 6-7, 9-12 and 10-11, 13-16 and 14-15, etc. This prevents the hybridization of in principle complementary bases within Ntypes/4 bases up and down along the backbone.

The exact functional form of the pair styles is rather complex. The individual potentials consist of products of modulation factors, which themselves are constructed from a number of more basic potentials (Morse, Lennard-Jones, harmonic angle and distance) as well as quadratic smoothing and modulation terms. We refer to (Ouldridge-DPhil) and (Ouldridge) for a detailed description of the oxDNA force field.

\textit{Note}: These pair styles have to be used together with the related oxDNA bond style \texttt{oxdna/fene} for the connectivity of the phosphate backbone (see also documentation of \texttt{bond_style oxdna/fene}). Most of the coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model. Exceptions are the first four coefficients after \texttt{oxdna/stk} (seq=seqdep, T=0.1, xi=1.3448 and kappa=2.6568 in the above example) and

18.356. \texttt{pair_style oxdna/coaxstk command}
the first coefficient after oxdna/hbond (seq=seqdep in the above example). When using a Langevin thermostat, e.g. through `fix langevin` or `fix nve/dotc/langevin` the temperature coefficients have to be matched to the one used in the fix.

Example input and data files for DNA duplexes can be found in examples/USER/cgdna/examples/oxDNA/ and /oxDNA2/. A simple python setup tool which creates single straight or helical DNA strands, DNA duplexes or arrays of DNA duplexes can be found in examples/USER/cgdna/util/.

Please cite (Henrich) in any publication that uses this implementation. The article contains general information on the model, its implementation and performance as well as the structure of the data and input file. The preprint version of the article can be found here. Please cite also the relevant oxDNA publications (Ouldridge), (Ouldridge-DPhil) and (Sulc).

### 18.356.4 Restrictions

These pair styles can only be used if LAMMPS was built with the USER-CGDNA package and the MOLECULE and ASPHERE package. See the Build package doc page for more info.

18.362.3 Description

The `oxdna2` pair styles compute the pairwise-additive parts of the oxDNA force field for coarse-grained modelling of DNA. The effective interaction between the nucleotides consists of potentials for the excluded volume interaction `oxdna2/excv`, the stacking `oxdna2/stk`, cross-stacking `oxdna2/xstk` and coaxial stacking interaction `oxdna2/coaxstk`, electrostatic Debye-Hueckel interaction `oxdna2/dh` as well as the hydrogen-bonding interaction `oxdna2/hbond` between complementary pairs of nucleotides on opposite strands. Average sequence or sequence-dependent stacking and base-pairing strengths are supported (Sulc). Quasi-unique base-pairing between nucleotides can be achieved by using more complementary pairs of atom types like 5-8 and 6-7, 9-12 and 10-11, 13-16 and 14-15, etc. This prevents the hybridization of in principle complementary bases within Ntypes/4 bases up and down along the backbone.

The exact functional form of the pair styles is rather complex. The individual potentials consist of products of modulation factors, which themselves are constructed from a number of more basic potentials (Morse, Lennard-Jones, harmonic angle and distance) as well as quadratic smoothing and modulation terms. We refer to (Snodin) and the original oxDNA publications (Ouldridge-DPhil) and (Ouldridge) for a detailed description of the oxDNA2 force field.

Note: These pair styles have to be used together with the related oxDNA2 bond style `oxdna2/fene` for the connectivity of the phosphate backbone (see also documentation of `bond_style oxdna2/fene`). Most of the coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model. Exceptions are the first four coefficients after `oxdna2/stk` (seq=seqdep, T=0.1, xi=1.3523 and kappa=2.6717 in the above example), the first coefficient after `oxdna2/hbond` (seq=seqdep in the above example) and the three coefficients after `oxdna2/dh` (T=0.1, rhos=0.5, qeff=0.815 in the above example). When using a Langevin thermostat e.g. through `fix langevin` or `fix nve/dotc/langevin` the temperature coefficients have to be matched to the one used in the fix.

Example input and data files for DNA duplexes can be found in examples/USER/cgdna/examples/oxDNA/ and /oxDNA2/. A simple python setup tool which creates single straight or helical DNA strands, DNA duplexes or arrays of DNA duplexes can be found in examples/USER/cgdna/util/.

Please cite (Henrich) in any publication that uses this implementation. The article contains general information on the model, its implementation and performance as well as the structure of the data and input file. The preprint version of the article can be found here. Please cite also the relevant oxDNA2 publications (Snodin) and (Sulc).
18.362.4 Restrictions

These pair styles can only be used if LAMMPS was built with the USER-CGDNA package and the MOLECULE and ASPHERE package. See the Build package doc page for more info.

1802  Chapter 18. Pair Styles
18.368.3 Description

The oxrna2 pair styles compute the pairwise-additive parts of the oxDNA force field for coarse-grained modelling of DNA. The effective interaction between the nucleotides consists of potentials for the excluded volume interaction oxrna2/excv, the stacking oxrna2/stk, cross-stacking oxrna2/xstk and coaxial stacking interaction oxrna2/coaxstk, electrostatic Debye-Hueckel interaction oxrna2/dh as well as the hydrogen-bonding interaction oxrna2/hbond between complementary pairs of nucleotides on opposite strands. Average sequence or sequence-dependent stacking and base-pairing strengths are supported (Sulc2). Quasi-unique base-pairing between nucleotides can be achieved by using more complementary pairs of atom types like 5-8 and 6-7, 9-12 and 10-11, 13-16 and 14-15, etc. This prevents the hybridization of in principle complementary bases within Ntypes/4 bases up and down along the backbone.

The exact functional form of the pair styles is rather complex. The individual potentials consist of products of modulation factors, which themselves are constructed from a number of more basic potentials (Morse, Lennard-Jones, harmonic angle and distance) as well as quadratic smoothing and modulation terms. We refer to (Sulc1) and the original oxDNA publications (Ouldridge-DPhil) and (Ouldridge) for a detailed description of the oxRNA2 force field.

Note: These pair styles have to be used together with the related oxDNA2 bond style oxrna2/fene for the connectivity of the phosphate backbone (see also documentation of bond_style oxrna2/fene). Most of the coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model. Exceptions are the first four coefficients after oxrna2/stk (seq=seqdep, T=0.1, xi=1.40206 and kappa=2.77 in the above example), the first coefficient after oxrna2/hbond (seq=seqdep in the above example) and the three coefficients after oxrna2/dh (T=0.1, rhos=0.5, qeff=1.02455 in the above example). When using a Langevin thermostat e.g. through fix langevin or fix nve/dotc/langevin the temperature coefficients have to be matched to the one used in the fix.

Example input and data files for DNA duplexes can be found in examples/USER/cgDNA/examples/oxDNA/ and /oxDNA2/. A simple python setup tool which creates single straight or helical DNA strands, DNA duplexes or arrays of DNA duplexes can be found in examples/USER/cgDNA/util/.

Please cite (Henrich) in any publication that uses this implementation. The article contains general information on the model, its implementation and performance as well as the structure of the data and input file. The preprint version of the article can be found here. Please cite also the relevant oxRNA2 publications (Sulc1) and (Sulc2).

18.368.4 Restrictions

These pair styles can only be used if LAMMPS was built with the USER-CGDN package and the MOLECULE and ASPHERE package. See the Build package doc page for more info.

18.374.3 Description

The peridynamic pair styles implement material models that can be used at the mesoscopic and macroscopic scales. See this document for an overview of LAMMPS commands for Peridynamics modeling.

Style `peri/pmb` implements the Peridynamic bond-based prototype microelastic brittle (PMB) model.

Style `peri/lps` implements the Peridynamic state-based linear peridynamic solid (LPS) model.

Style `peri/ves` implements the Peridynamic state-based linear peridynamic viscoelastic solid (VES) model.

Style `peri/eps` implements the Peridynamic state-based elastic-plastic solid (EPS) model.
The canonical papers on Peridynamics are (Silling 2000) and (Silling 2007). The implementation of Peridynamics in LAMMPS is described in (Parks). Also see the PDLAMMPS user guide for more details about its implementation.

The peridynamic VES and EPS models in PDLAMMPS were implemented by R. Rahman and J. T. Foster at University of Texas at San Antonio. The original VES formulation is described in “(Mitchell2011)” and the original EPS formulation is in “(Mitchell2011a)”. Additional PDF docs that describe the VES and EPS implementations are include in the LAMMPS distribution in doc/PDF/PDLammps_VES.pdf and doc/PDF/PDLammps_EPS.pdf. For questions regarding the VES and EPS models in LAMMPS you can contact R. Rahman (rezwanur.rahman at utsa.edu).

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below.

For the peri/pmb style:
- c (energy/distance/volume^2 units)
- horizon (distance units)
- s00 (unitless)
- α (unitless)

C is the effectively a spring constant for Peridynamic bonds, the horizon is a cutoff distance for truncating interactions, and s00 and α are used as a bond breaking criteria. The units of c are such that c/distance = stiffness/volume^2, where stiffness is energy/distance^2 and volume is distance^3. See the users guide for more details.

For the peri/lps style:
- K (force/area units)
- G (force/area units)
- horizon (distance units)
- s00 (unitless)
- α (unitless)

K is the bulk modulus and G is the shear modulus. The horizon is a cutoff distance for truncating interactions, and s00 and α are used as a bond breaking criteria. See the users guide for more details.

For the peri/ves style:
- K (force/area units)
- G (force/area units)
- horizon (distance units)
- s00 (unitless)
- α (unitless)
- m_lambdai (unitless)
- m_taubi (unitless)

K is the bulk modulus and G is the shear modulus. The horizon is a cutoff distance for truncating interactions, and s00 and α are used as a bond breaking criteria. m_lambdai and m_taubi are the viscoelastic relaxation parameter and time constant, respectively. m_lambdai varies within zero to one. For very small values of m_lambdai the viscoelastic model responds very similar to a linear elastic model. For details please see the description in “(Mtchell2011)”.

For the peri/eps style:
- K (force/area units)

18.374. pair_style peri/eps command
• G (force/area units)
• horizon (distance units)
• s00 (unitless)
• α (unitless)
• m_yield_stress (force/area units)

K is the bulk modulus and G is the shear modulus. The horizon is a cutoff distance and s00 and α are used as a bond breaking criteria. m_yield_stress is the yield stress of the material. For details please see the description in “(Mtchell2011a)”.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These pair styles do not support the pair_modify shift option.

The pair_modify table and tail options are not relevant for these pair styles.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

18.374.4 Restrictions

All of these styles are part of the PERI package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.374.5 Related commands

pair_coeff * * CuTa_eam.poly Cu Ta
pair_coeff * * GaN_tersoff.poly Ga N
pair_coeff * * GaN_sw.poly Ga N
```

18.375.3 Description

The polymorphic pair style computes a 3-body free-form potential (Zhou3) for the energy E of a system of atoms as

\[
E = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} \sum_{k=i, k \neq j} \left[ (1 - \delta_{ij}) \cdot U_{IJ}(r_{ij}) - (1 - \eta_{ij}) \cdot F_{IJ}(X_{ij}) \cdot V_{IJ}(r_{ij}) \right]
\]

\[
X_{ij} = \sum_{k=i, k \neq j}^{i_N} W_{IK}(r_{ik}) \cdot G_{JIK}(\cos \theta_{jik}) \cdot P_{JIK}(\Delta r_{jik})
\]

\[
\Delta r_{jik} = r_{ij} - \xi_{IJ} \cdot r_{ik}
\]

where I, J, K represent species of atoms i, j, and k, \(i_1, \ldots, i_N\) represents a list of i’s neighbors, \(\delta_{ij}\) is a Dirac constant (i.e., \(\delta_{ij} = 1\) when \(i = j\), and \(\delta_{ij} = 0\) otherwise), \(\eta_{ij}\) is similar constant that can be set either to \(\eta_{ij} = \delta_{ij}\) or \(\eta_{ij} = 1 - \delta_{ij}\) depending on the potential type, \(U_{IJ}(r_{ij})\), \(V_{IJ}(r_{ij})\), \(W_{IK}(r_{ik})\) are pair functions, \(G_{JIK}(\cos \theta_{jik})\) is an angular function, \(P_{JIK}(\Delta r_{jik})\) is a function of atomic spacing differential \(\Delta r_{jik} = r_{ij} - \xi_{IJ} \cdot r_{ik}\) with \(\xi_{IJ}\) being a pair-dependent parameter, and \(F_{IJ}(X_{ij})\) is a function of the local environment variable \(X_{ij}\). This generic potential is fully defined once the constants \(\eta_{ij}\) and \(\xi_{IJ}\), and the six functions \(U_{IJ}(r_{ij})\), \(V_{IJ}(r_{ij})\), \(W_{IK}(r_{ik})\), \(G_{JIK}(\cos \theta_{jik})\), \(P_{JIK}(\Delta r_{jik})\), and \(F_{IJ}(X_{ij})\) are given. Here LAMMPS uses a global parameter \(\eta\) to represent \(\eta_{ij}\). When \(\eta = 1\), \(\eta_{ij} = 1 - \delta_{ij}\), otherwise \(\eta_{ij} = \delta_{ij}\). Additionally, \(\eta = 3\) indicates that the function \(P_{JIK}(\Delta r)\) depends on species I, J and K, otherwise \(P_{JIK}(\Delta r) = P_{IK}(\Delta r)\) only depends on species I and K. Note that these six functions are all one dimensional, and hence can be provided in a tabular form. This allows users to design different potentials solely based
on a manipulation of these functions. For instance, the potential reduces to a Stillinger-Weber potential \((SW)\) if we set 

\[
\eta_{ij} = \delta_{ij} (\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 0
\]

\[
U_{IJ} (r) = A_{IJ} \cdot \epsilon_{IJ} \cdot \left( \frac{\sigma_{IJ}}{r} \right)^q \cdot \left[ B_{IJ} \cdot \left( \frac{\sigma_{IJ}}{r} \right)^{p-q} - 1 \right] \cdot \exp \left( \frac{\sigma_{IJ}}{r - a_{IJ} \cdot \sigma_{IJ}} \right)
\]

\[
V_{IJ} (r) = \sqrt{\lambda_{IJ} \cdot \epsilon_{IJ} \cdot \exp \left( \frac{\gamma_{IJ} \cdot \sigma_{IJ}}{r - a_{IJ} \cdot \sigma_{IJ}} \right)}
\]

\[
F_{IJ} (X) = -X
\]

\[
P_{JIK} (\Delta r) = P_{IK} (\Delta r) = 1
\]

\[
W_{IJ} (r) = \sqrt{\lambda_{IJ} \cdot \epsilon_{IJ} \cdot \exp \left( \frac{\gamma_{IJ} \cdot \sigma_{IJ}}{r - a_{IJ} \cdot \sigma_{IJ}} \right)}
\]

\[
G_{JIK} (\cos \theta) = \left( \cos \theta + \frac{1}{3} \right)^2
\]

The potential reduces to a Tersoff potential \((Tersoff \text{ or } Albe)\) if we set

\[
\eta_{ij} = \delta_{ij} (\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 1
\]

\[
U_{IJ} (r) = \varphi_{R,ij} (r - \varphi_{A,ij} (r))
\]

\[
V_{IJ} (r) = u_{IJ} (r)
\]

\[
F_{IJ} (X) = -X
\]

\[
P_{JIK} (\Delta r) = P_{IK} (\Delta r) = \exp (2 \mu_{IK} \cdot \Delta r)
\]

\[
W_{IJ} (r) = u_{IJ} (r)
\]

\[
G_{JIK} (\cos \theta) = g_{JIK} (\cos \theta)
\]

where

\[
f_{c,ij} (r) = \begin{cases} 
1, & r \leq R_{ij} - D_{ij} \\
\frac{1}{2} + \frac{1}{2} \cos \left[ \frac{\pi (r - D_{ij} - R_{ij})}{2D_{ij}} \right], & R_{ij} - D_{ij} < r < R_{ij} + D_{ij} \\
0, & r \geq R_{ij} + D_{ij}
\end{cases}
\]

The potential reduces to a modified Stillinger-Weber potential \((Zhou3)\) if we set

\[
\eta_{ij} = \delta_{ij} (\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 0
\]

\[
U_{IJ} (r) = \varphi_{R,ij} (r) - \varphi_{A,ij} (r)
\]

\[
V_{IJ} (r) = u_{IJ} (r)
\]

\[
F_{IJ} (X) = -X
\]

\[
P_{JIK} (\Delta r) = P_{IK} (\Delta r) = 1
\]

\[
W_{IJ} (r) = u_{IJ} (r)
\]

\[
G_{JIK} (\cos \theta) = g_{JIK} (\cos \theta)
\]
The potential reduces to a Rockett-Tersoff potential ([Wang3] if we set
\[
\eta_{ij} = \delta_{ij}(\eta = 2) \text{ or } \eta_{ij} = 0, \quad \xi_{IJ} = 1
\]
\[
U_{IJ} (r) = A_{IJ} \exp \left( -\lambda_{1, IJ} \cdot r \right) f_{c, IJ} (r) f_{ca, IJ} (r)
\]
\[
V_{IJ} (r) = \left\{ \frac{B_{IJ} \exp \left( -\lambda_{2, IJ} \cdot r \right) f_{c, IJ} (r) + A_{IJ} \exp \left( -\lambda_{1, IJ} \cdot r \right) f_{c, IJ} (r) \left[ 1 - f_{ca, IJ} (r) \right] }{f_{ca, IJ} (r)} \right\}
\]
\[
F_{IJ} (X) = \left[ 1 + (\beta_{IJ} X)^{n_{IJ}} \right]^{-\frac{1}{n_{IJ}}}
\]
\[
P_{JIK} (\Delta r) = P_{IK} (\Delta r) = \exp \left( \lambda_{3, IK} \cdot \Delta r^3 \right)
\]
\[
W_{IJ} (r) = f_{c, IJ} (r)
\]
\[
G_{JJK} (\cos \theta) = 1 + \frac{c_{JK}^2}{d_{JK}^2} - \frac{c_{JK}^2}{d_{JK}^2 + (h_{JK} + \cos \theta)^2}
\]
where \( f_{ca, IJ} (r) \) is similar to the \( f_{c, IJ} (r) \) defined above:
\[
f_{ca, IJ} (r) = \begin{cases} 1, r \leq R_{a, IJ} - D_{a, IJ} \\ \frac{1}{2} + \frac{1}{2} \cos \left[ \frac{\pi (r + D_{a, IJ} - R_{a, IJ})}{2D_{a, IJ}} \right], R_{a, IJ} - D_{a, IJ} < r < R_{a, IJ} + D_{a, IJ} \\ 0, r \geq R_{a, IJ} + D_{a, IJ} \end{cases}
\]
The potential becomes the embedded atom method ([Daw] if we set
\[
\eta_{ij} = 1 - \delta_{ij}(\eta = 1), \quad \xi_{IJ} = 0
\]
\[
U_{IJ} (r) = \phi_{IJ} (r)
\]
\[
V_{IJ} (r) = 1
\]
\[
F_{IJ} (X) = -2F_{I} (X)
\]
\[
P_{JIK} (\Delta r) = P_{IK} (\Delta r) = 1
\]
\[
W_{IJ} (r) = f_{J} (r)
\]
\[
G_{JJK} (\cos \theta) = 1
\]
In the embedded atom method case, \( \phi_{IJ} (r) \) is the pair energy, \( F_{I} (X) \) is the embedding energy, \( X \) is the local electron density, and \( f_{J} (r) \) is the atomic electron density function.

The potential reduces to another type of Tersoff potential ([Zhou4] if we set
\[
\eta_{ij} = \delta_{ij}(\eta = 3), \quad \xi_{IJ} = 1
\]
\[
U_{IJ} (r) = \frac{D_{IJ}}{S_{IJ} - 1} \cdot \exp \left[ -\beta_{IJ} \sqrt{2S_{IJ}} \left( r - r_{e, IJ} \right) \right] \cdot f_{c, IJ} (r) \cdot T_{IJ} (r) + V_{ZBLIJ} (r) \left[ 1 - T_{IJ} (r) \right]
\]
\[
V_{IJ} (r) = \frac{S_{IJ} \cdot D_{IJ}}{S_{IJ} - 1} \cdot \exp \left[ -\beta_{IJ} \sqrt{2S_{IJ}} \left( r - r_{e, IJ} \right) \right] \cdot f_{c, IJ} (r) \cdot T_{IJ} (r)
\]
\[
F_{IJ} (X) = (1 + X)^{-\frac{1}{2}}
\]
\[
P_{JIK} (\Delta r) = \omega_{JIK} \cdot \exp \left( \alpha_{JIK} \cdot \Delta r \right)
\]
\[
W_{IJ} (r) = f_{c, IJ} (r)
\]
\[
G_{JJK} (\cos \theta) = \gamma_{JJK} \left[ 1 + \frac{c_{JK}^2}{d_{JK}^2} - \frac{c_{JK}^2}{d_{JK}^2 + (h_{JK} + \cos \theta)^2} \right]
\]
\[
T_{IJ} (r) = \frac{1}{1 + \exp \left[ -b_{f, IJ} (r - r_{f, IJ}) \right]}
\]
\[
V_{ZBLIJ} (r) = 14.4 \cdot \frac{Z_{I} \cdot Z_{J}}{r} \sum_{k=1}^{4} \mu_{k} \cdot \exp \left[ -v_{k} \left( Z_{I}^{0.23} + Z_{J}^{0.23} \right) r \right]
\]
where \( f_{c, IJ} (r) \) is the same as defined above. This Tersoff potential differs from the one above because the \( P_{JIK} (\Delta r) \) function is now dependent on all three species I, J, and K.
If the tabulated functions are created using the parameters of Stillinger-Weber, Tersoff, and EAM potentials, the polymorphic pair style will produce the same global properties (energies and stresses) and the same forces as the *sw*, *tersoff*, and *eam* pair styles. The polymorphic pair style also produces the same per-atom properties (energies and stresses) as the corresponding *tersoff* and *eam* pair styles. However, due to a different partitioning of global properties to per-atom properties, the polymorphic pair style will produce different per-atom properties (energies and stresses) as the *sw* pair style. This does not mean that polymorphic pair style is different from the *sw* pair style. It just means that the definitions of the atom energies and atom stresses are different.

Only a single pair_coeff command is used with the polymorphic pair style which specifies a potential file for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of polymorphic potential elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file. Several files for polymorphic potentials are included in the potentials directory of the LAMMPS distribution. They have a “poly” suffix.

As an example, imagine the GaN_tersoff.poly file has tabulated functions for Ga-N tersoff potential. If your LAMMPS simulation has 4 atom types and you want the first 3 to be Ga, and the fourth to be N, you would use the following pair_coeff command:

```
pair_coeff * * GaN_tersoff.poly Ga Ga Ga N
```

The first two arguments must be * * to span all pairs of LAMMPS atom types. The first three Ga arguments map LAMMPS atom types 1,2,3 to the Ga element in the polymorphic file. The final N argument maps LAMMPS atom type 4 to the N element in the polymorphic file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when an polymorphic potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Potential files in the potentials directory of the LAMMPS distribution have a “.poly” suffix. At the beginning of the files, an unlimited number of lines starting with ‘#’ are used to describe the potential and are ignored by LAMMPS. The next line lists two numbers:

```
ntypes eta
```

Here ntypes represent total number of species defined in the potential file, η = 1 reduces to embedded atom method, η = 3 assumes a three species dependent \( P_{JK}(\Delta r) \) function, and all other values of η assume a two species dependent \( P_{JK}(\Delta r) \) function. The value of ntypes must equal the total number of different species defined in the pair_coeff command. The next ntypes lines each lists two numbers and a character string representing atomic number, atomic mass, and name of the species of the ntypes elements:

```
atomic-number atomic-mass element-name(1)
atomic-number atomic-mass element-name(2)
... 
atomic-number atomic-mass element-name(ntypes)
```

The next line contains four numbers:

```
r ntheta nx xmax
```

Here nr is total number of tabular points for radial functions U, V, W, P, ntheta is total number of tabular points for the angular function G, nx is total number of tabular points for the function F, xmax is a maximum value of the argument of function F. Note that the pair functions \( U_{IJ}(r) \), \( V_{IJ}(r) \), \( W_{IJ}(r) \) are uniformly tabulated between 0 and cutoff distance of the IJ pair, \( G_{JK}(\cos \theta) \) is uniformly tabulated between -1 and 1, \( P_{JK}(\Delta r) \) is uniformly tabulated between -rcmax and rcmax where rcmax is the maximum cutoff distance of all pairs, and \( F_{IJ}(X) \) is uniformly tabulated between 0 and xmax. Linear extrapolation is assumed if actual simulations exceed these ranges.
The next $ntypes*(ntypes+1)/2$ lines contain two numbers:

```plaintext
cut xi(1)
cut xi(2)
...
cut xi(ntypes*(ntypes+1)/2)
```

Here cut means the cutoff distance of the pair functions, “xi” is $\xi$ as defined in the potential functions above. The $ntypes*(ntypes+1)/2$ lines are related to the pairs according to the sequence of first ii (self) pairs, $i = 1, 2, \ldots, ntypes$, and then ij (cross) pairs, $i = 1, 2, \ldots, ntypes-1$, and $j = i+1, i+2, \ldots, ntypes$ (i.e., the sequence of the ij pairs follows $11, 22, \ldots, 12, 13, 14, \ldots, 23, 24, \ldots$).

In the final blocks of the potential file, $U$, $V$, $W$, $P$, $G$, and $F$ functions are listed sequentially. First, $U$ functions are given for each of the $ntypes*(ntypes+1)/2$ pairs according to the sequence described above. For each of the pairs, $nr$ values are listed. Next, similar arrays are given for $V$ and $W$ functions. If $P$ functions depend only on pair species, i.e., $\eta \neq 3$, then $P$ functions are also listed the same way the next. If $P$ functions depend on three species, i.e., $\eta = 3$, then $P$ functions are listed for all the $ntypes*ntypes*ntypes$ IJK triplets in a natural sequence I from 1 to $ntypes$, J from 1 to $ntypes$, and K from 1 to $ntypes$ (i.e., IJK = 111, 112, 113, ..., 121, 122, 123 ..., 211, 212, ...). Next, $G$ functions are listed for all the $ntypes*ntypes*ntypes$ IJK triplets similarly. For each of the $G$ functions, $ntheta$ values are listed. Finally, $F$ functions are listed for all the $ntypes*(ntypes+1)/2$ pairs in the same sequence as described above. For each of the $F$ functions, $nx$ values are listed.

**Mixing, shift, table tail correction, restart:**

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

## 18.375.4 Restrictions

If using `create_atoms` command, atomic masses must be defined in the input script. If using `read_data`, atomic masses must be defined in the atomic structure data file.

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

This pair potential requires the `newton` setting to be “on” for pair interactions.

The potential files provided with LAMMPS (see the potentials directory) are parameterized for metal `units`. You can use any LAMMPS units, but you would need to create your own potential files.

## 18.375.5 Related commands

`pair_coeff`

18.376 pair_style python command

18.376.1 Syntax

```
pair_style python cutoff
```

cutoff = global cutoff for interactions in python potential classes

18.376.2 Examples

```
pair_style python 2.5
pair_coeff * * py_pot.LJCutMelt lj

pair_style hybrid/overlay coul/long 12.0 python 12.0
pair_coeff * * coul/long
pair_coeff * * python py_pot.LJCutSPCE OW NULL
```

18.376.3 Description

The *python* pair style provides a way to define pairwise additive potential functions as python script code that is loaded into LAMMPS from a python file which must contain specific python class definitions. This allows to rapidly evaluate different potential functions without having to modify and re-compile LAMMPS. Due to python being an interpreted language, however, the performance of this pair style is going to be significantly slower (often between 20x and 100x) than corresponding compiled code. This penalty can be significantly reduced through generating tabulations from the python code through the `pair_write` command, which is supported by this style.

Only a single pair_coeff command is used with the `python` pair style which specifies a python class inside a python module or file that LAMMPS will look up in the current directory, the folder pointed to by the LAMMPS_POTENTIALS environment variable or somewhere in your python path. A single python module can hold multiple python pair class definitions. The class definitions itself have to follow specific rules that are explained below.

Atom types in the python class are specified through symbolic constants, typically strings. These are mapped to LAMMPS atom types by specifying N additional arguments after the class name in the pair_coeff command, where N must be the number of currently defined atom types:

As an example, imagine a file `py_pot.py` has a python potential class names `LJCutMelt` with parameters and potential functions for a two Lennard-Jones atom types labeled as ‘LJ1’ and ‘LJ2’. In your LAMMPS input and you would have defined 3 atom types, out of which the first two are supposed to be using the ‘LJ1’ parameters and the third the ‘LJ2’ parameters, then you would use the following pair_coeff command:

```
pair_coeff * * py_pot.LJCutMelt LJ1 LJ1 LJ2
```

The first two arguments **must** be * * so as to span all LAMMPS atom types. The first two LJ1 arguments map LAMMPS atom types 1 and 2 to the LJ1 atom type in the LJCutMelt class of the `py_pot.py` file. The final LJ2 argument maps LAMMPS atom type 3 to the LJ2 atom type the python file. If a mapping value is specified as NULL, the mapping is not performed, any pair interaction with this atom type will be skipped. This can be used when a *python*
potential is used as part of the hybrid or hybrid/overlay pair style. The NULL values are then placeholders for atom types that will be used with other potentials.

The python potential file has to start with the following code:

```python
from __future__ import print_function

class LAMMSPairPotential(object):
    def __init__(self):
        self.pmap = dict()
        self.units = 'lj'
    def map_coeff(self, name, ltype):
        self.pmap[ltype] = name
    def check_units(self, units):
        if (units != self.units):
            raise Exception("Conflicting units: %s vs. %s" % (self.units, units))
```

Any classes with definitions of specific potentials have to be derived from this class and should be initialize in a similar fashion to the example given below.

**Note:** The class constructor has to set up a data structure containing the potential parameters supported by this class. It should also define a variable `self.units` containing a string matching one of the options of LAMMPS’ `units` command, which is used to verify, that the potential definition in the python class and in the LAMMPS input match.

Here is an example for a single type Lennard-Jones potential class *LJCutMelt* in reduced units, which defines an atom type *lj* for which the parameters epsilon and sigma are both 1.0:

```python
class LJCutMelt(LAMMSPairPotential):
    def __init__(self):
        super(LJCutMelt, self).__init__()
        self.units = 'lj'
        self.coeff = {'lj' : {'lj' : (48.0, 24.0, 4.0, 4.0)}}
```

The class also has to provide two methods for the computation of the potential energy and forces, which have been named *compute_force*, and *compute_energy*, which both take 3 numerical arguments:

• `rsq` = the square of the distance between a pair of atoms (float)

• `itype` = the (numerical) type of the first atom

• `jtype` = the (numerical) type of the second atom

This functions need to compute the force and the energy, respectively, and use the result as return value. The functions need to use the `pmap` dictionary to convert the LAMMPS atom type number to the symbolic value of the internal potential parameter data structure. Following the *LJCutMelt* example, here are the two functions:

```python
def compute_force(self, rsq, itype, jtype):
    coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
    r2inv = 1.0/rsq
    r6inv = r2inv*r2inv*r2inv
    lj1 = coeff[0]
    lj2 = coeff[1]
    return (r6inv * (lj1*r6inv - lj2))*r2inv
```

(continues on next page)
```python
def compute_energy(self, rsq, itype, jtype):
    coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
    r2inv = 1.0 / rsq
    r6inv = r2inv * r2inv * r2inv
    lj3 = coeff[2]
    lj4 = coeff[3]
    return (r6inv * (lj3 * r6inv - lj4))
```

**Note:** for consistency with the C++ pair styles in LAMMPS, the `compute_force` function follows the conventions of the Pair::single() methods and does not return the full force, but the force scaled by the distance between the two atoms, so this value only needs to be multiplied by delta x, delta y, and delta z to conveniently obtain the three components of the force vector between these two atoms.

**Note:** The evaluation of scripted python code will slow down the computation pair-wise interactions quite significantly. However, this can be largely worked around through using the python pair style not for the actual simulation, but to generate tabulated potentials on the fly using the `pair_write` command. Please see below for an example LAMMPS input of how to build a table file:

```
pair_style python 2.5
pair_coeff * * py_pot.LJCutMelt lj
shell rm -f melt.table
pair_write 1 1 2000 rsq 0.01 2.5 lj1_lj2.table lj
```

Note that it is strongly recommended to try to delete the potential table file before generating it. Since the `pair_write` command will always append to a table file, while pair style table will use the first match. Thus when changing the potential function in the python class, the table pair style will still read the old variant unless the table file is first deleted.

After switching the pair style to `table`, the potential tables need to be assigned to the LAMMPS atom types like this:

```
pair_style       table linear 2000
pair_coeff     1 1 melt.table lj
```

This can also be done for more complex systems. Please see the `examples/python` folders for a few more examples.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

Mixing of potential parameters has to be handled inside the provided python module. The python pair style simply assumes that force and energy computation can be correctly performed for all pairs of atom types as they are mapped to the atom type labels inside the python potential class.

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.
18.376.4 Restrictions

This pair style is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the 
Build package doc page for more info.

18.376.5 Related commands

pair_coeff, pair_write, pair style table

Default: none

18.377 pair_style quip command

18.377.1 Syntax

```
pair_style quip
```

18.377.2 Examples

```
pair_style quip
pair_coeff  * * gap_example.xml "Potential xml_label=GAP_2014_5_8_60_17_10_38_466 =" 14
pair_coeff  * * sw_example.xml "IP SW" 14
```

18.377.3 Description

Style quip provides an interface for calling potential routines from the QUIP package. QUIP is built separately, and 
then linked to LAMMPS. The most recent version of the QUIP package can be downloaded from GitHub: 
https://github.com/libAtoms/QUIP. The interface is chiefly intended to be used to run Gaussian Approximation 
Potentials (GAP), which are described in the following publications: (Bartok et al) and (PhD thesis of Bartok).

Only a single pair_coeff command is used with the quip style that specifies a QUIP potential file containing the 
parameters of the potential for all needed elements in XML format. This is followed by a QUIP initialization string. 
Finally, the QUIP elements are mapped to LAMMPS atom types by specifying N atomic numbers, where N is the 
type of LAMMPS atom types:

- QUIP filename
- QUIP initialization string
- N atomic numbers = mapping of QUIP elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

A QUIP potential is fully specified by the filename which contains the parameters of the potential in XML format, the 
initialization string, and the map of atomic numbers.

GAP potentials can be obtained from the Data repository section of http://www.libatoms.org, where the appropriate 
initialization strings are also advised. The list of atomic numbers must be matched to the LAMMPS atom types 
specified in the LAMMPS data file or elsewhere.

Two examples input scripts are provided in the examples/USER/quip directory.
Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.377.4 Restrictions

This pair style is part of the USER-QUIP package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

QUIP potentials are parameterized in electron-volts and Angstroms and therefore should be used with LAMMPS metal units.

QUIP potentials are generally not designed to work with the scaling factors set by the special_bonds command. The recommended setting in molecular systems is to include all interactions, i.e. to use special_bonds lj/coul 1.0 1.0 1.0. Scaling factors > 0.0 will be ignored and treated as 1.0. The only exception to this rule is if you know that your QUIP potential needs to exclude bonded, 1-3, or 1-4 interactions and does not already do this exclusion within QUIP. Then a factor 0.0 needs to be used which will remove such pairs from the neighbor list. This needs to be very carefully tested, because it may remove pairs from the neighbor list that are still required.

pair_style reax/c NULL safezone 1.6 mincap 100
pair_coeff * * ffield.reax C H O N
```

18.380.3 Description

Style `reax/c` computes the ReaxFF potential of van Duin, Goddard and co-workers. ReaxFF uses distance-dependent bond-order functions to represent the contributions of chemical bonding to the potential energy. There is more than one version of ReaxFF. The version implemented in LAMMPS uses the functional forms documented in the supplemental information of the following paper: (Chenoweth et al., 2008). The version integrated into LAMMPS matches the most up-to-date version of ReaxFF as of summer 2010. For more technical details about the pair reax/c implementation of ReaxFF, see the (Aktulga) paper. The `reax/c` style was initially implemented as a stand-alone C code and is now integrated into LAMMPS as a package.

The `reax/c/kk` style is a Kokkos version of the ReaxFF potential that is derived from the `reax/c` style. The Kokkos version can run on GPUs and can also use OpenMP multithreading. For more information about the Kokkos package, see Packages details and Speed kokkos doc pages. One important consideration when using the `reax/c/kk` style is the choice of either half or full neighbor lists. This setting can be changed using the Kokkos package command.

The `reax/c` style differs from the (obsolete) “pair_style reax” command in the implementation details. The `reax` style was a Fortran library, linked to LAMMPS. The `reax` style has been removed from LAMMPS after the 12 December 2018 version.

LAMMPS provides several different versions of ffield.reax in its potentials dir, each called potentials/ffield.reax.label. These are documented in potentials/README.reax. The default ffield.reax contains parameterizations for the following elements: C, H, O, N.

The format of these files is identical to that used originally by van Duin. We have tested the accuracy of `pair_style reax/c` potential against the original ReaxFF code for the systems mentioned above. You can use other ffield files for specific chemical systems that may be available elsewhere (but note that their accuracy may not have been tested).

Note: We do not distribute a wide variety of ReaxFF force field files with LAMMPS. Adri van Duin’s group at PSU is the central repository for this kind of data as they are continuously deriving and updating parameterizations for different classes of materials. You can submit a contact request at the Materials Computation Center (MCC) website https://www.mri.psu.edu/materials-computation-center/connect-mcc, describing the material(s) you are interested in modeling with ReaxFF. They can tell you what is currently available or what it would take to create a suitable ReaxFF parameterization.

The `cfile` setting can be specified as NULL, in which case default settings are used. A control file can be specified which defines values of control variables. Some control variables are global parameters for the ReaxFF potential. Others define certain performance and output settings. Each line in the control file specifies the value for a control variable. The format of the control file is described below.

18.380. pair_style reax/c/omp command

---

```
lgvdw value = yes or no = whether or not to use a low gradient vdw correction
safezone = factor used for array allocation
mincap = minimum size for array allocation
minhbonds = minimum size use for storing hydrogen bonds
```

---

1817
Note: The LAMMPS default values for the ReaxFF global parameters correspond to those used by Adri van Duin’s stand-alone serial code. If these are changed by setting control variables in the control file, the results from LAMMPS and the serial code will not agree.

Examples using pair_style reax/c are provided in the examples/reax sub-directory.

Use of this pair style requires that a charge be defined for every atom. See the atom_style and read_data commands for details on how to specify charges.

The ReaxFF parameter files provided were created using a charge equilibration (QEq) model for handling the electrostatic interactions. Therefore, by default, LAMMPS requires that the fix qeq/reax command be used with pair_style reax/c when simulating a ReaxFF model, to equilibrate charge each timestep. Using the keyword checkqeq with the value no turns off the check for fix qeq/reax, allowing a simulation to be run without charge equilibration. In this case, the static charges you assign to each atom will be used for computing the electrostatic interactions in the system. See the fix qeq/reax command for details.

Using the optional keyword lgvdw with the value yes turns on the low-gradient correction of the ReaxFF/C for long-range London Dispersion, as described in the (Liu) paper. Force field file ffield.reax.lg is designed for this correction, and is trained for several energetic materials (see “Liu”). When using lg-correction, recommended value for parameter thb is 0.01, which can be set in the control file. Note: Force field files are different for the original or lg corrected pair styles, using wrong ffield file generates an error message.

Using the optional keyword enobonds with the value yes, the energy of atoms with no bonds (i.e. isolated atoms) is included in the total potential energy and the per-atom energy of that atom. If the value no is specified then the energy of atoms with no bonds is set to zero. The latter behavior is usual not desired, as it causes discontinuities in the potential energy when the bonding of an atom drops to zero.

Optional keywords safezone, mincap, and minhbonds are used for allocating reax/c arrays. Increasing these values can avoid memory problems, such as segmentation faults and bondchk failed errors, that could occur under certain conditions. These keywords are not used by the Kokkos version, which instead uses a more robust memory allocation scheme that checks if the sizes of the arrays have been exceeded and automatically allocates more memory.

The thermo variable evdwl stores the sum of all the ReaxFF potential energy contributions, with the exception of the Coulombic and charge equilibration contributions which are stored in the thermo variable ecoul. The output of these quantities is controlled by the thermo command.

This pair style tallies a breakdown of the total ReaxFF potential energy into sub-categories, which can be accessed via the compute pair command as a vector of values of length 14. The 14 values correspond to the following sub-categories (the variable names in italics match those used in the original FORTRAN ReaxFF code):

1. \( eb = \) bond energy
2. \( ea = \) atom energy
3. \( elp = \) lone-pair energy
4. \( emol = \) molecule energy (always 0.0)
5. \( ev = \) valence angle energy
6. \( open = \) double-bond valence angle penalty
7. \( ecoa = \) valence angle conjugation energy
8. \( ebh = \) hydrogen bond energy
9. \( et = \) torsion energy
10. \( eco = \) conjugation energy
11. \( ew = \) van der Waals energy
12. $ep = $Coulomb energy
13. $efi = $electric field energy (always 0.0)
14. $eqeq = $charge equilibration energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```plaintext
compute reax all pair reax/c
variable eb equal c_reax[1]
variable ea equal c_reax[2]
[...]
variable eqeq equal c_reax[14]
thermo_style custom step temp epair v_eb v_ea [...] v_eqeq
```

Only a single pair_coeff command is used with the reax/c style which specifies a ReaxFF potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N indices = ReaxFF elements

The filename is the ReaxFF potential file.

In the ReaxFF potential file, near the top, after the general parameters, is the atomic parameters section that contains element names, each with a couple dozen numeric parameters. If there are M elements specified in the field file, think of these as numbered 1 to M. Each of the N indices you specify for the N atom types of LAMMPS atoms must be an integer from 1 to M. Atoms with LAMMPS type 1 will be mapped to whatever element you specify as the first index value, etc. If a mapping value is specified as NULL, the mapping is not performed. This can be used when the reax/c style is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

As an example, say your LAMMPS simulation has 4 atom types and the elements are ordered as C, H, O, N in the field file. If you want the LAMMPS atom type 1 and 2 to be C, type 3 to be N, and type 4 to be H, you would use the following pair_coeff command:

```plaintext
pair_coeff * * ffield.reax C C N H
```

The format of a line in the control file is as follows:

```plaintext
variable_name value
```

and it may be followed by an “!” character and a trailing comment.

If the value of a control variable is not specified, then default values are used. What follows is the list of variables along with a brief description of their use and default values.

- simulation_name: Output files produced by pair_style reax/c carry this name + extensions specific to their contents. Partial energies are reported with a “.pot” extension, while the trajectory file has “.trj” extension.
- tabulate_long_range: To improve performance, long range interactions can optionally be tabulated (0 means no tabulation). Value of this variable denotes the size of the long range interaction table. The range from 0 to long range cutoff (defined in the field file) is divided into tabulate_long_range points. Then at the start of simulation, we fill in the entries of the long range interaction table by computing the energies and forces resulting from van der Waals and Coulomb interactions between every possible atom type pairs present in the input system. During the simulation we consult to the long range interaction table to estimate the energy and forces between a pair of atoms. Linear interpolation is used for estimation. (default value = 0)
energy_update_freq: Denotes the frequency (in number of steps) of writes into the partial energies file. (default value = 0)

bsphood_cutoff: Denotes the near neighbors cutoff (in Angstroms) regarding the bonded interactions. (default value = 5.0)

hbond_cutoff: Denotes the cutoff distance (in Angstroms) for hydrogen bond interactions. (default value = 7.5. A value of 0.0 turns off hydrogen bonds)

bond_graph_cutoff: is the threshold used in determining what is a physical bond, what is not. Bonds and angles reported in the trajectory file rely on this cutoff. (default value = 0.3)

thb_cutoff: cutoff value for the strength of bonds to be considered in three body interactions. (default value = 0.001)

thb_cutoff_sq: cutoff value for the strength of bond order products to be considered in three body interactions. (default value = 0.00001)

write_freq: Frequency of writes into the trajectory file. (default value = 0)

traj_title: Title of the trajectory - not the name of the trajectory file.

atom_info: 1 means print only atomic positions + charge (default = 0)

atom_forces: 1 adds net forces to atom lines in the trajectory file (default = 0)

atom_velocities: 1 adds atomic velocities to atoms line (default = 0)

bond_info: 1 prints bonds in the trajectory file (default = 0)

angle_info: 1 prints angles in the trajectory file (default = 0)

---

Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

---

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
18.380.4 Restrictions

This pair style is part of the USER-REAXC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The ReaxFF potential files provided with LAMMPS in the potentials directory are parameterized for real units. You can use the ReaxFF potential with any LAMMPS units, but you would need to create your own potential file with coefficients listed in the appropriate units if your simulation does not use “real” units.

```
pair_style resquared 10.0
pair_coeff * * 1.0 1.0 1.7 3.4 3.4 1.0 1.0 1.0
```
18.383.3 Description

Style *resquared* computes the RE-squared anisotropic interaction \((\textit{Everaers}), (\textit{Babadi})\) between pairs of ellipsoidal and/or spherical Lennard-Jones particles. For ellipsoidal interactions, the potential considers the ellipsoid as being comprised of small spheres of size \(\sigma\). LJ particles are a single sphere of size \(\sigma\). The distinction is made to allow the pair style to make efficient calculations of ellipsoid/solvent interactions.

Details for the equations used are given in the references below and in this supplementary document.

Use of this pair style requires the NVE, NVT, or NPT fixes with the *asphere* extension (e.g. \textit{fix nve/asphere}) in order to integrate particle rotation. Additionally, *atom_style ellipsoid* should be used since it defines the rotational state and the size and shape of each ellipsoidal particle.

The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands:

- \(A_{12}\) = Energy Prefactor/Hamaker constant (energy units)
- \(\sigma\) = atomic interaction diameter (distance units)
- \(\epsilon_{i,a}\) = relative well depth of type I for side-to-side interactions
- \(\epsilon_{i,b}\) = relative well depth of type I for face-to-face interactions
- \(\epsilon_{i,c}\) = relative well depth of type I for end-to-end interactions
- \(\epsilon_{j,a}\) = relative well depth of type J for side-to-side interactions
- \(\epsilon_{j,b}\) = relative well depth of type J for face-to-face interactions
- \(\epsilon_{j,c}\) = relative well depth of type J for end-to-end interactions
- cutoff (distance units)

The parameters used depend on the type of the interacting particles, i.e. ellipsoids or LJ spheres. The type of a particle is determined by the diameters specified for its 3 shape parameters. If all 3 shape parameters = 0.0, then the particle is treated as an LJ sphere. The \(\epsilon_{i,*}\) or \(\epsilon_{j,*}\) parameters are ignored for LJ spheres. If the 3 shape parameters are > 0.0, then the particle is treated as an ellipsoid (even if the 3 parameters are equal to each other).

\(A_{12}\) specifies the energy prefactor which depends on the types of the two interacting particles.

For ellipsoid/ellipsoid interactions, the interaction is computed by the formulas in the supplementary document referenced above. \(A_{12}\) is the Hamaker constant as described in \((\textit{Everaers})\). In LJ units:

\[
A_{12} = 4\pi^2 \epsilon_{LJ} (\rho \sigma^3)^2
\]

where \(\rho\) gives the number density of the spherical particles composing the ellipsoids and \(\epsilon_{LJ}\) determines the interaction strength of the spherical particles.

For ellipsoid/LJ sphere interactions, the interaction is also computed by the formulas in the supplementary document referenced above. \(A_{12}\) has a modified form (see here for details):

\[
A_{12} = 4\pi^2 \epsilon_{LJ} (\rho \sigma^3)
\]

For ellipsoid/LJ sphere interactions, a correction to the distance- of-closest approach equation has been implemented to reduce the error from two particles of disparate sizes; see this supplementary document.

For LJ sphere/LJ sphere interactions, the interaction is computed using the standard Lennard-Jones formula, which is much cheaper to compute than the ellipsoidal formulas. \(A_{12}\) is used as epsilon in the standard LJ formula:

\[
A_{12} = \epsilon_{LJ}
\]

and the specified \(\sigma\) is used as the \(\sigma\) in the standard LJ formula.
When one of both of the interacting particles are ellipsoids, then $\sigma$ specifies the diameter of the continuous distribution of constituent particles within each ellipsoid used to model the RE-squared potential. Note that this is a different meaning for $\sigma$ than the pair_style gayberne potential uses.

The $\epsilon_i$ and $\epsilon_j$ coefficients are defined for atom types, not for pairs of atom types. Thus, in a series of pair_coeff commands, they only need to be specified once for each atom type.

Specifically, if any of $\epsilon_{i,a}$, $\epsilon_{i,b}$, $\epsilon_{i,c}$ are non-zero, the three values are assigned to atom type I. If all the $\epsilon_i$ values are zero, they are ignored. If any of $\epsilon_{j,a}$, $\epsilon_{j,b}$, $\epsilon_{j,c}$ are non-zero, the three values are assigned to atom type J. If all three $\epsilon_i$ values are zero, they are ignored. Thus the typical way to define the $\epsilon_i$ and $\epsilon_j$ coefficients is to list their values in “pair_coeff I J” commands when $I = J$, but set them to 0.0 when $I != J$. If you do list them when $I != J$, you should insure they are consistent with their values in other pair_coeff commands.

Note that if this potential is being used as a sub-style of pair_style hybrid, and there is no “pair_coeff I I” setting made for RE-squared for a particular type I (because I-I interactions are computed by another hybrid pair potential), then you still need to insure the epsilon $a,b,c$ coefficients are assigned to that type in a “pair_coeff I J” command.

For large uniform molecules it has been shown that the $\epsilon_{+,+}$ energy parameters are approximately representable in terms of local contact curvatures (Everaers):

$$
\epsilon_a = \sigma \cdot \frac{a}{b \cdot c};
\epsilon_b = \sigma \cdot \frac{b}{a \cdot c};
\epsilon_c = \sigma \cdot \frac{c}{a \cdot b}
$$

where $a$, $b$, and $c$ give the particle diameters.

The last coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I != J, the epsilon and sigma coefficients and cutoff distance can be mixed, but only for sphere pairs. The default mix value is geometric. See the “pair_modify” command for details. Other type pairs cannot be mixed, due to the different meanings of the energy prefactors used to calculate the interactions and the implicit dependence of the ellipsoid-sphere interaction on the equation for the Hamaker constant presented here. Mixing of sigma and epsilon followed by calculation of the energy prefactors using the equations above is recommended.

This pair styles supports the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction, but only for sphere-sphere interactions. There is no shifting performed for ellipsoidal interactions due to the anisotropic dependence of the interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.
This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords of the run_style command.

18.383.4 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires that atoms be ellipsoids as defined by the atom_style ellipsoid command.

Particles acted on by the potential can be finite-size aspherical or spherical particles, or point particles. Spherical particles have all 3 of their shape parameters equal to each other. Point particles have all 3 of their shape parameters equal to 0.0.

The distance-of-closest-approach approximation used by LAMMPS becomes less accurate when high-aspect ratio ellipsoids are used.

pair_style  lj/sdk/coul/msm  10.0
pair_style  lj/sdk/coul/msm  10.0 12.0
pair_coeff   1 1 lj9_6 100.0 3.5 12.0
```
18.392.3 Description

The \( \text{lj/sdk} \) styles compute a 9/6, 12/4, or 12/6 Lennard-Jones potential, given by

\[
E = \frac{27}{4} \epsilon \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^6 \quad r < r_c
\]

\[
E = 3\sqrt{3} \frac{\epsilon}{2} \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^4 \quad r < r_c
\]

\[
E = 4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \quad r < r_c
\]

as required for the SDK Coarse-grained MD parameterization discussed in (Shinoda) and (DeVane). \( r_c \) is the cutoff.

Style \( \text{lj/sdk/coul/long} \) computes the adds Coulombic interactions with an additional damping factor applied so it can be used in conjunction with the \( \text{kspace_style} \) command and its \( \text{ewald} \) or \( \text{pppm} \) or \( \text{pppm/cg} \) option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

The following coefficients must be defined for each pair of atoms types via the \( \text{pair_coeff} \) command as in the examples above, or in the data file or restart files read by the \( \text{read_data} \) or \( \text{read_restart} \) commands, or by mixing as described below:

- \( \text{cg_type} \) (lj9_6, lj12_4, or lj12_6)
- \( \text{epsilon} \) (energy units)
- \( \text{sigma} \) (distance units)
- \( \text{cutoff1} \) (distance units)

Note that \( \text{sigma} \) is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum. The prefactors are chosen so that the potential minimum is at \(-\epsilon\).

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the \( \text{pair_style} \) command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

For \( \text{lj/sdk/coul/long} \) and \( \text{lj/sdk/coul/msm} \) only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the \( \text{pair_style} \) command.

Styles with a \( \text{gpu} \), \( \text{intel} \), \( \text{kk} \), \( \text{omp} \) or \( \text{opt} \) suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \( \text{Speed packages} \) doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP, and OPT packages respectively. They are only enabled if LAMMPS was built with those packages. See the \( \text{Build package} \) doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \( -\text{suffix} \) command-line switch when you invoke LAMMPS, or you can use the \( \text{suffix} \) command in your input script.

See the \( \text{Speed packages} \) doc page for more instructions on how to use the accelerated styles effectively.

**Mixing, shift, table, tail correction, restart, and rRESPA info:**

For atom type pairs \( I \) and \( J \neq I \), the epsilon and sigma coefficients and cutoff distance for all of the \( \text{lj/sdk} \) pair styles cannot be mixed, since different pairs may have different exponents. So all parameters for all pairs have to be specified...
explicitly through the “pair_coeff” command. Defining then in a data file is also not supported, due to limitations of
that file format.

All of the lj/sdk pair styles support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair
interaction.

The lj/sdk/coul/long pair styles support the pair_modify table option since they can tabulate the short-range portion of
the long-range Coulombic interaction.

All of the lj/sdk pair styles write their information to binary restart files, so pair_style and pair_coeff commands do
not need to be specified in an input script that reads a restart file.

The lj/sdk and lj/cut/coul/long pair styles do not support the use of the inner, middle, and outer keywords of the
run_style respa command.

18.392.4 Restrictions

All of the lj/sdk pair styles are part of the USER-CGSDK package. The lj/sdk/coul/long style also requires the KSPACE
package to be built (which is enabled by default). They are only enabled if LAMMPS was built with that package. See
the Build package doc page for more info.

18.393 pair_style sdpd/taitwater/isothermal command

18.393.1 Syntax

pair_style sdpd/taitwater/isothermal temperature viscosity seed

- temperature = temperature of the fluid (temperature units)
- viscosity = dynamic viscosity of the fluid (mass*distance/time units)
- seed = random number generator seed (positive integer, optional)
18.393.2 Examples

```plaintext
pair_style sdpd/taitwater/isothermal 300.0 1.0 28681
pair_coeff * * 1000.0 1430.0 2.4
```

18.393.3 Description

The sdpd/taitwater/isothermal style computes forces between mesoscopic particles according to the Smoothed Dissipative Particle Dynamics model described in this paper by (Espanol and Revenga) under the following assumptions:

1. The temperature is constant and uniform.
2. The shear viscosity is constant and uniform.
3. The volume viscosity is negligible before the shear viscosity.
4. The Boltzmann constant is negligible before the heat capacity of a single mesoscopic particle of fluid.

The third assumption is true for water in nearly incompressible flows. The fourth holds true for water for any reasonable size one can imagine for a mesoscopic particle.

The pressure forces between particles will be computed according to Tait’s equation of state:

\[ p = B \left( \frac{\rho}{\rho_0} \right)^\gamma - 1 \]

where \( \gamma = 7 \) and \( B = \frac{c_0^2 \rho_0}{\gamma} \), with \( \rho_0 \) being the reference density and \( c_0 \) the reference speed of sound.

The laminar viscosity and the random forces will be computed according to formulas described in (Espanol and Revenga).

**Warning:** Similar to `brownian` and `dpd` styles, the `newton` setting for pairwise interactions needs to be on when running LAMMPS in parallel if you want to ensure linear momentum conservation. Otherwise random forces generated for pairs straddling processor boundary will not be equal and opposite.

**Note:** The actual random seed used will be a mix of what you specify and other parameters like the MPI ranks. This is to ensure that different MPI tasks have distinct seeds.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above.

- \( \rho_0 \) reference density (mass/volume units)
- \( c_0 \) reference soundspeed (distance/time units)
- \( h \) kernel function cutoff (distance units)

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the `pair_modify` shift, table, and tail options.

This style does not write information to binary restart files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.
This style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.393.4 Restrictions

This pair style is part of the USER-SDPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.393.5 Related commands

pair coeff, pair sph/rhosum, pair sph/taitwater

18.393.6 Default

The default seed is 0 (before mixing).

18.394 pair_style smd/hertz command

18.394.1 Syntax

pair_style smd/hertz scale_factor

18.394.2 Examples

pair_style smd/hertz 1.0
pair_coeff 1 1 <contact_stiffness>

18.394.3 Description

The smd/hertz style calculates contact forces between SPH particles belonging to different physical bodies.

The contact forces are calculated using a Hertz potential, which evaluates the overlap between two particles (whose spatial extents are defined via its contact radius). The effect is that a particles cannot penetrate into each other. The parameter <contact_stiffness> has units of pressure and should equal roughly one half of the Young’s modulus (or bulk modulus in the case of fluids) of the material model associated with the SPH particles.

The parameter scale_factor can be used to scale the particles’ contact radii. This can be useful to control how close particles can approach each other. Usually, scale_factor =1.0.

Mixing, shift, table, tail correction, restart, rRESPA info:

No mixing is performed automatically. Currently, no part of USER-SMD supports restarting nor minimization. rRESPA does not apply to this pair style.
18.394 Restrictions

This fix is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.395 pair_style smd/tlsph command

18.395.1 Syntax

pair_style smd/tlsph args

18.395.2 Examples

pair_style smd/tlsph

18.395.3 Description

The smd/tlsph style computes particle interactions according to continuum mechanics constitutive laws and a Total-Lagrangian Smooth-Particle Hydrodynamics algorithm.

This pair style is invoked with the following command:

pair_style smd/tlsph
pair_coeff i j *COMMON rho0 E nu Q1 Q2 hg Cp &
*END

Here, \( i \) and \( j \) denote the LAMMPS particle types for which this pair style is defined. Note that \( i \) and \( j \) must be equal, i.e., no tlsph cross interactions between different particle types are allowed. In contrast to the usual LAMMPS pair coeff definitions, which are given solely a number of floats and integers, the tlsph pair coeff definition is organized using keywords. These keywords mark the beginning of different sets of parameters for particle properties, material constitutive models, and damage models. The pair coeff line must be terminated with the *END keyword. The use the line continuation operator & is recommended. A typical invocation of the tlsph for a solid body would consist of an equation of state for computing the pressure (the diagonal components of the stress tensor), and a material model to compute shear stresses (the off-diagonal components of the stress tensor). Damage and failure models can also be added.

Please see the SMD user guide for a complete listing of the possible keywords and material models.

Mixing, shift, table, tail correction, restart, rRESPA info:

No mixing is performed automatically. Currently, no part of USER-SMD supports restarting nor minimization. rRESPA does not apply to this pair style.
18.395.4 Restrictions

This fix is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

pair_style smd/tri_surface scale_factor
```

18.396.2 Examples

```
pair_style smd/tri_surface 1.0
pair_coeff 1 1 <contact_stiffness>
```

18.396.3 Description

The `smd/tri_surface` style calculates contact forces between SPH particles and a rigid wall boundary defined via the `smd/wall_surface` fix.

The contact forces are calculated using a Hertz potential, which evaluates the overlap between a particle (whose spatial extents are defined via its contact radius) and the triangle. The effect is that a particle cannot penetrate into the triangular surface. The parameter `<contact_stiffness>` has units of pressure and should equal roughly one half of the Young’s modulus (or bulk modulus in the case of fluids) of the material model associated with the SPH particle.

The parameter `scale_factor` can be used to scale the particles’ contact radii. This can be useful to control how close particles can approach the triangulated surface. Usually, `scale_factor = 1.0`.

Mixing, shift, table, tail correction, restart, rRESPA info:

No mixing is performed automatically. Currently, no part of USER-SMD supports restarting nor minimization. rRESPA does not apply to this pair style.
18.396.4 Restrictions

This fix is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.396.5 Related commands

pair_coeff

Default: none

18.397 pair_style smd/ulsph command

18.397.1 Syntax

```
pair_style smd/ulsph args
```

- these keywords must be given

```
keyword = *DENSITY_SUMMATION or *DENSITY_CONTINUITY and *VELOCITY_GRADIENT
or *NO_VELOCITY_GRADIENT and *GRADIENT_CORRECTION or *NO_GRADIENT_CORRECTION
```

18.397.2 Examples

```
pair_style smd/ulsph *DENSITY_CONTINUITY *VELOCITY_GRADIENT *NO_GRADIENT_CORRECTION
```

18.397.3 Description

The smd/ulsph style computes particle interactions according to continuum mechanics constitutive laws and an updated Lagrangian Smooth-Particle Hydrodynamics algorithm.

This pair style is invoked similar to the following command:

```
pair_style smd/ulsph *DENSITY_CONTINUITY *VELOCITY_GRADIENT *NO_GRADIENT_CORRECTION
pair_coeff i j *COMMON rho0 c0 Q1 Cp hg &
  *END
```

Here, \( i \) and \( j \) denote the LAMMPS particle types for which this pair style is defined. Note that \( i \) and \( j \) can be different, i.e., ulsph cross interactions between different particle types are allowed. However, \( i-i \) respectively \( j-j \) pair_coeff lines have to precede a cross interaction. In contrast to the usual LAMMPS pair coeff definitions, which are given solely a number of floats and integers, the ulsph pair coeff definition is organized using keywords. These keywords mark the beginning of different sets of parameters for particle properties, material constitutive models, and damage models. The pair coeff line must be terminated with the *END keyword. The use the line continuation operator & is recommended. A typical invocation of the ulsph for a solid body would consist of an equation of state for computing the pressure (the diagonal components of the stress tensor), and a material model to compute shear stresses (the off-diagonal components of the stress tensor).

Note that the use of *GRADIENT_CORRECTION can lead to severe numerical instabilities. For a general fluid simulation, *NO_GRADIENT_CORRECTION is recommended.
Please see the SMD user guide for a complete listing of the possible keywords and material models.

Mixing, shift, table, tail correction, restart, rRESPA info:

No mixing is performed automatically. Currently, no part of USER-SMD supports restarting nor minimization. rRESPA does not apply to this pair style.

18.397.4 Restrictions

This fix is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

pair_coeff

Default: none

18.398 pair_style smtbq command

18.398.1 Syntax

pair_style smtbq

18.398.2 Examples

pair_style smtbq
pair_coeff * * ffield.smtbq.Al2O3 O Al

18.398.3 Description

This pair style computes a variable charge SMTB-Q (Second-Moment tight-Binding QEq) potential as described in SMTB-Q_1 and SMTB-Q_2. Briefly, the energy of metallic-oxygen systems is given by three contributions:

\[ E_{tot} = E_{ES} + E_{OO} + E_{MO} \]

\[ E_{ES} = \sum_{i} \left[ \chi_{i}Q_{i} + \frac{1}{2} J_{i}Q_{i}^{2} + \frac{1}{2} \sum_{j \neq i} J_{ij}(r_{ij})f_{cut}^{R_{cut}}(r_{ij})Q_{i}Q_{j} \right] \]

\[ E_{OO} = \sum_{i,j=O} \left[ C\exp\left(-\frac{r_{ij}}{\rho}\right) - Df_{cut}^{O_{O}}r_{ij}^{2}\exp(Br_{ij}) \right] \]

\[ E_{MO} = \sum_{i} E_{cov}^{i} + \sum_{j \neq i} A f_{cut}^{r_{ij}}(r_{ij})\exp\left[-p_{i}\frac{r_{ij}}{r_{0}} - 1\right] \]

where \( E_{tot} \) is the total potential energy of the system, \( E_{ES} \) is the electrostatic part of the total energy, \( E_{OO} \) is the interaction between oxygen atoms and \( E_{MO} \) is a short-range interaction between metal and oxygen atoms. This
interactions depend on interatomic distance $r_{ij}$ and/or the charge $Q_i$ of atoms $i$. Cut-off function enables smooth convergence to zero interaction.

The parameters appearing in the upper expressions are set in the ffield.SMTBQ.Syst file where Syst corresponds to the selected system (e.g. ffield.SMTBQ.Al2O3). Examples for TiO$_2$, Al$_2$O$_3$ are provided. A single pair_coeff command is used with the SMTBQ styles which provides the path to the potential file with parameters for needed elements. These are mapped to LAMMPS atom types by specifying additional arguments after the potential filename in the pair_coeff command. Note that atom type 1 must always correspond to oxygen atoms. As an example, to simulate a TiO$_2$ system, atom type 1 has to be oxygen and atom type 2 Ti. The following pair_coeff command should then be used:

```
pair_coeff * * PathToLammps/potentials/ffield.smtbq.TiO2 O Ti
```

The electrostatic part of the energy consists of two components

self-energy of atom $i$ in the form of a second order charge dependent polynomial and a long-range Coulombic electrostatic interaction. The latter uses the wolf summation method described in Wolf, spherically truncated at a longer cutoff, $R_{coul}$. The charge of each ion is modeled by an orbital Slater which depends on the principal quantum number ($n$) of the outer orbital shared by the ion.

Interaction between oxygen, $E_{OO}$, consists of two parts, an attractive and a repulsive part. The attractive part is effective only at short range ($< r_{OO}^2$). The attractive contribution was optimized to study surfaces reconstruction (e.g. SMTB-Q_2 in TiO$_2$) and is not necessary for oxide bulk modeling. The repulsive part is the Pauli interaction between the electron clouds of oxygen. The Pauli repulsion and the coulombic electrostatic interaction have same cut off value.

In the ffield.SMTBQ.Syst, the keyword ‘buck’ allows to consider only the repulsive O-O interactions. The keyword ‘buckPlusAttr’ allows to consider the repulsive and the attractive O-O interactions.

The short-range interaction between metal-oxygen, $E_{MO}$ is based on the second moment approximation of the density of states with a N-body potential for the band energy term, $E_{cov}$, and a Born-Mayer type repulsive terms as indicated by the keyword ‘second_moment’ in the ffield.SMTBQ.Syst. The energy band term is given by:

$$E_{cov(i=M,O)} = -\left\{ \eta_i (\mu \xi^0)^2 r_{cut}^2 (r_{ij}) \left( \sum_{j(j=O,M)} e^{[2(2q(r_{ij} - r_0) - 1)]} \delta Q_i (2 \frac{n_0}{\eta_i} - \delta Q_i) \right) \right\}^{1/2}$$

where $\eta_i$ is the stoichiometry of atom $i$, $\delta Q_i$ is the charge delocalization of atom $i$, compared to its formal charge $Q_i^F$. $n_0$, the number of hybridized orbitals, is calculated with to the atomic orbitals shared $d_i$ and the stoichiometry $\eta_i$. $r_{c1}$ and $r_{c2}$ are the two cutoff radius around the four neighbors in the cutoff function.

In the formalism used here, $\xi^0$ is the energy parameter. $\xi^0$ is in tight-binding approximation the hopping integral between the hybridized orbitals of the cation and the anion. In the literature we find many ways to write the hopping integral depending on whether one takes the point of view of the anion or cation. These are equivalent vision. The correspondence between the two visions is explained in appendix A of the article in the SrTiO$_3$ SMTB-Q_3 (parameter $\beta$ shown in this article is in fact the $\beta_Q$). To summarize the relationship between the hopping integral $\xi^O$ and the others, we have in an oxide C$_n$O$_m$ the following relationship:

$$\frac{\beta_O}{\sqrt{m}} = \frac{\beta_C}{\sqrt{n}} = \xi^0 \frac{\sqrt{m} + \sqrt{n}}{2}$$

Thus parameter $\mu$, indicated above, is given by $\mu = \frac{1}{2} (\sqrt{n} + \sqrt{m})$

The potential offers the possibility to consider the polarizability of the electron clouds of oxygen by changing the slater radius of the charge density around the oxygen atoms through the parameters $r_{BB}$, $r_B$ and $r_S$ in the ffield.SMTBQ.Syst. This change in radius is performed according to the method developed by E. Maras SMTB-Q_2. This method needs to determine the number of nearest neighbors around the oxygen. This calculation is based on first ($r_{1n}$) and second ($r_{2n}$) distances neighbors.
The SMTB-Q potential is a variable charge potential. The equilibrium charge on each atom is calculated by the electronegativity equalization (QEq) method. See Rick for further detail. One can adjust the frequency, the maximum number of iterative loop and the convergence of the equilibrium charge calculation. To obtain the energy conservation in NVE thermodynamic ensemble, we recommend to use a convergence parameter in the interval 10e-5 - 10e-6 eV.

The ffield.SMTBQ.Syst files are provided for few systems. They consist of nine parts and the lines beginning with ‘#’ are comments (note that the number of comment lines matter). The first sections are on the potential parameters and others are on the simulation options and might be modified. Keywords are character type and must be enclosed in quotation marks ("').

1) Number of different element in the oxide:
   - N_elem= 2 or 3
   - Divider line

2) Atomic parameters
   For the anion (oxygen)
   - Name of element (char) and stoichiometry in oxide
   - Formal charge and mass of element
   - Principal quantum number of outer orbital n), electronegativity ($\chi^0_i$) and hardness ($J^0_i$)
   - Ionic radius parameters : max coordination number (coordBB = 6 by default), bulk coordination number (coordB), surface coordination number (coordS) and rBB, rB and rS the slater radius for each coordination number.
     (note : If you don’t want to change the Slater radius, use three identical radius values)
   - Number of orbital shared by the element in the oxide ($d_i$)
   - Divider line

   For each cations (metal):
   - Name of element (char) and stoichiometry in oxide
   - Formal charge and mass of element
   - Number of electron in outer orbital (ne), electronegativity ($\chi^0_i$), hardness ($J^0_i$) and rSlater the slater radius for the cation.
   - Number of orbitals shared by the elements in the oxide ($d_i$)
   - Divider line

3) Potential parameters:
   - Keyword for element1, element2 and interaction potential (‘second_moment’ or ‘buck’ or ‘buckPlusAttr’) between element 1 and 2. If the potential is ‘second_moment’, specify ‘oxide’ or ‘metal’ for metal-oxide or metal-metal interactions respectively.
   - Potential parameter:
     - If type of potential is ‘second_moment’ : A (eV), $p$, $\zeta^0$ (eV) and $q$, $r_{c1} (\textrm{\AA})$, $r_{c2} (\textrm{\AA})$ and $r_0 (\textrm{\AA})$
     - If type of potential is ‘buck’ : $C$ (eV) and $\rho (\textrm{\AA})$
     - If type of potential is ‘buckPlusAttr’ : $C$ (eV) and $\rho (\textrm{\AA})$ $D$ (eV), $B$ (Å$^{-1}$), $r_1^{OO} (\textrm{\AA})$ and $r_2^{OO} (\textrm{\AA})$
   - Divider line

4) Tables parameters:
   - Cutoff radius for the Coulomb interaction ($R_{coul}$)
   - Starting radius ($r_{min} = 1,18845\textrm{\AA}$) and increments ($dr = 0.001\textrm{\AA}$) for creating the potential table.

18.398. pair_style smtbq command
5) Rick model parameter:
   - Nevery : parameter to set the frequency of the charge resolution. The charges are evaluated each Nevery time steps.
   - Max number of iterative loop (loopmax) and convergence criterion (prec) in eV of the charge resolution

6) Coordination parameter:
   - First (r1n) and second (r2n) neighbor distances in angstrom

7) Charge initialization mode:
   - Keyword (QInitMode) and initial oxygen charge (Qinit). If keyword = ‘true’, all oxygen charges are initially set equal to Qinit. The charges on the cations are initially set in order to respect the neutrality of the box. If keyword = ‘false’, all atom charges are initially set equal to 0 if you use the create_atoms command or the charge specified in the file structure using read_data command.

8) Mode for the electronegativity equalization (Qeq)
   - Keyword (mode) followed by:
     - QEqAll (one QEq group) | no parameters
     - QEqAllParallel (several QEq groups) | no parameters
     - Surface | zlim (QEq only for z>zlim)
   - Parameter if necessary

9) Verbose
   - If you want the code to work in verbose mode or not : ‘true’ or ‘false’
   - If you want to print or not in the file ‘Energy_component.txt’ the three main contributions to the energy of the system according to the description presented above : ‘true’ or ‘false’ and NEnergy. This option writes to the file every NEnergy time steps. If the value is ‘false’ then NEnergy = 0. The file takes into account the possibility to have several QEq groups g then it writes: time step, number of atoms in group g, electrostatic part of energy, EES, the interaction between oxygen, EO, and short range metal-oxygen interaction, EMO.
   - If you want to print to the file ‘Electroneg_component.txt’ the electronegativity component (\( \partial E_{\text{tot}} / \partial Q_i \)) or not: ‘true’ or ‘false’ and Nev. This option writes to the file every Nev time steps. If the value is ‘false’ then Nev = 0. The file consist of atom number i, atom type (1 for oxygen and # higher than 1 for metal), atom position: x, y and z, atomic charge of atom i, electrostatic part of atom i electronegativity, covalent part of atom i electronegativity, the hopping integral of atom i (Z\( \beta^2 \)) and box electronegativity.

Note: This last option slows down the calculation dramatically. Use only with a single processor simulation.

Mixing, shift, table, tail correction, restart, rRESPA info:
This pair style does not support the pair_modify mix, shift, table, and tail options.
This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

Restriction:

This pair style is part of the USER-SMTBQ package and is only enabled if LAMMPS is built with that package. See the Build package doc page for more info.

This potential requires using atom type 1 for oxygen and atom type higher than 1 for metal atoms.

This pair style requires the newton setting to be “on” for pair interactions.

The SMTB-Q potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units.

Citing this work:

18.399 pair_style snap command

18.400 pair_style snap/kk command

18.400.1 Syntax

```plaintext
pair_style snap
```

18.400.2 Examples

```plaintext
pair_style snap
pair_coeff * * InP.snapcoeff InP.snapparam In In P
```
18.400.3 Description

Pair style snap defines the spectral neighbor analysis potential (SNAP), a machine-learning interatomic potential (Thompson). Like the GAP framework of Bartok et al. (Bartok2010), SNAP uses bispectrum components to characterize the local neighborhood of each atom in a very general way. The mathematical definition of the bispectrum calculation and its derivatives w.r.t. atom positions is identical to that used by compute snap, which is used to fit SNAP potentials to ab initio energy, force, and stress data. In SNAP, the total energy is decomposed into a sum over atom energies. The energy of atom $i$ is expressed as a weighted sum over bispectrum components.

$$E_{SNAP}^i(B_1^i, ..., B_K^i) = \beta^\mu_i^0 + \sum_{k=1}^{K} \beta^\mu_i^k B_k^i$$

where $B_k^i$ is the $k$-th bispectrum component of atom $i$, and $\beta^\mu_i^k$ is the corresponding linear coefficient that depends on $\mu_i$, the SNAP element of atom $i$. The number of bispectrum components used and their definitions depend on the value of twojmax and other parameters defined in the SNAP parameter file described below. The bispectrum calculation is described in more detail in compute sna/atom.

Note that unlike for other potentials, cutoffs for SNAP potentials are not set in the pair_style or pair_coeff command; they are specified in the SNAP potential files themselves.

Only a single pair_coeff command is used with the snap style which specifies a SNAP coefficient file followed by a SNAP parameter file and then N additional arguments specifying the mapping of SNAP elements to LAMMPS atom types, where N is the number of LAMMPS atom types:

- SNAP coefficient file
- SNAP parameter file
- N element names = mapping of SNAP elements to atom types

As an example, if a LAMMPS indium phosphide simulation has 4 atoms types, with the first two being indium and the third and fourth being phosphorous, the pair_coeff command would look like this:

```
pair_coeff * * snap InP.snapcoeff InP.snapparam In In P P
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The two filenames are for the coefficient and parameter files, respectively. The two trailing ‘In’ arguments map LAMMPS atom types 1 and 2 to the SNAP ‘In’ element. The two trailing ‘P’ arguments map LAMMPS atom types 3 and 4 to the SNAP ‘P’ element.

If a SNAP mapping value is specified as NULL, the mapping is not performed. This can be used when a snap potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The name of the SNAP coefficient file usually ends in the “.snapcoeff” extension. It may contain coefficients for many SNAP elements. The only requirement is that it contain at least those element names appearing in the LAMMPS mapping list. The name of the SNAP parameter file usually ends in the “.snapparam” extension. It contains a small number of parameters that define the overall form of the SNAP potential. See the pair_coeff doc page for alternate ways to specify the path for these files.

Quite commonly, SNAP potentials are combined with one or more other LAMMPS pair styles using the hybrid/overlay pair style. As an example, the SNAP tantalum potential provided in the LAMMPS potentials directory combines the snap and zbl pair styles. It is invoked by the following commands:

```
variable zblcutinner equal 4
variable zblcutouter equal 4.8
variable zblz equal 73
pair_style hybrid/overlay &
zbl ${zblcutinner} ${zblcutouter} snap
```

(continues on next page)
pair_coeff * * zbl 0.0
pair_coeff 1 1 zbl ${zblz}$
pair_coeff * * snap Ta06A.snapcoeff Ta06A.snapparam Ta

It is convenient to keep these commands in a separate file that can be inserted in any LAMMPS input script using the `include` command.

The top of the SNAP coefficient file can contain any number of blank and comment lines (start with #), but follows a strict format after that. The first non-blank non-comment line must contain two integers:

- `nelem` = Number of elements
- `ncoeff` = Number of coefficients

This is followed by one block for each of the `nelem` elements. The first line of each block contains three entries:

- Element symbol (text string)
- `R` = Element radius (distance units)
- `w` = Element weight (dimensionless)

This line is followed by `ncoeff` coefficients, one per line.

The SNAP parameter file can contain blank and comment lines (start with #) anywhere. Each non-blank non-comment line must contain one keyword/value pair. The required keywords are `rcutfac` and `twojmax`. Optional keywords are `rfac0`, `rmin0`, `switchflag`, `hzeroflag`, `quadraticflag`, `chemflag`, `bnormflag`, `wselfallflag`, and `chunksize`.

The default values for these keywords are

- `rfac0` = 0.99363
- `rmin0` = 0.0
- `switchflag` = 1
- `hzeroflag` = 1
- `quadraticflag` = 0
- `chemflag` = 0
- `bnormflag` = 0
- `wselfallflag` = 0
- `chunksize` = 2000

If `quadraticflag` is set to 1, then the SNAP energy expression includes additional quadratic terms that have been shown to increase the overall accuracy of the potential without much increase in computational cost (Wood).

\[ E_{SNAP}^i(B^i) = \beta_0^\mu_i + \beta^\mu_i \cdot B_i + \frac{1}{2} B_j^i \cdot \alpha^\mu_i \cdot B_i \]

where \( B_i \) is the \( K \)-vector of bispectrum components, \( \beta^\mu_i \) is the \( K \)-vector of linear coefficients for element \( \mu_i \), and \( \alpha^\mu_i \) is the symmetric \( K \) by \( K \) matrix of quadratic coefficients. The SNAP element file should contain \( K(K+1)/2 \) additional coefficients for each element, the upper-triangular elements of \( \alpha^\mu_i \).

If `chemflag` is set to 1, then the energy expression is written in terms of explicit multi-element bispectrum components indexed on ordered triplets of elements, which has been shown to increase the ability of the SNAP potential to capture energy differences in chemically complex systems, at the expense of a significant increase in computational cost (Cusentino).

\[ E_{SNAP}^i(B^i) = \beta_0^\mu_i + \sum_{\kappa,\lambda,\mu} \beta^\kappa\lambda\mu \cdot B_i^\kappa\lambda\mu \]
where $\mathbf{B}^{\kappa\lambda\mu}$ is the $K$-vector of bispectrum components for neighbors of elements $\kappa$, $\lambda$, and $\mu$ and $\beta^{\kappa\lambda\mu}$ is the corresponding $K$-vector of linear coefficients for element $\mu_i$. The SNAP element file should contain a total of $KN_{\text{elem}}^3$ coefficients for each of the $N_{\text{elem}}$ elements.

The keyword `chunksize` is only applicable when using the pair style `snap` with the KOKKOS package and is ignored otherwise. This keyword controls the number of atoms in each pass used to compute the bispectrum components and is used to avoid running out of memory. For example if there are 4000 atoms in the simulation and the `chunksize` is set to 2000, the bispectrum calculation will be broken up into two passes.

Detailed definitions for all the other keywords are given on the `compute sna/atom` doc page.

**Note:** The previously used `diagonalstyle` keyword was removed in 2019, since all known SNAP potentials use the default value of 3.

---

**Mixing, shift, table, tail correction, restart, rRESPA info:**

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a pair_coeff command with I != J arguments for this style.

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

---

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

---

**18.400.4 Restrictions**

This style is part of the SNAP package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.
18.400.5 Related commands

*compute sna/atom, compute snad/atom, compute snav/atom, compute snap*

**Default:** none

18.401 pair_style soft command

18.402 pair_style soft/gpu command

18.403 pair_style soft/omp command

18.403.1 Syntax

```
pair_style soft cutoff
```

- cutoff = global cutoff for soft interactions (distance units)

18.403.2 Examples

```
pair_style soft 1.0
pair_coeff * * 10.0
pair_coeff 1 1 10.0 3.0

pair_style soft 1.0
pair_coeff * * 0.0
variable prefactor equal ramp(0,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

18.403.3 Description

Style *soft* computes pairwise interactions with the formula

\[
E = A \left[ 1 + \cos \left( \frac{\pi r}{r_c} \right) \right] \quad r < r_c
\]

It is useful for pushing apart overlapping atoms, since it does not blow up as \( r \) goes to 0. A is a pre-factor that can be made to vary in time from the start to the end of the run (see discussion below), e.g. to start with a very soft potential and slowly harden the interactions over time. \( r_c \) is the cutoff. See the *fix nve/limit* command for another way to push apart overlapping atoms.
The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- A (energy units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global soft cutoff is used.

**Note:** The syntax for `pair_coeff` with a single A coeff is different in the current version of LAMMPS than in older versions which took two values, Astart and Astop, to ramp between them. This functionality is now available in a more general form through the `fix adapt` command, as explained below. Note that if you use an old input script and specify Astart and Astop without a cutoff, then LAMMPS will interpret that as A and a cutoff, which is probably not what you want.

The `fix adapt` command can be used to vary A for one or more pair types over the course of a simulation, in which case `pair_coeff` settings for A must still be specified, but will be overridden. For example these commands will vary the prefactor A for all pairwise interactions from 0.0 at the beginning to 30.0 at the end of a run:

```plaintext
variable prefactor equal ramp(0,30)
f1 all adapt 1 pair soft a * * v_prefactor
```

Note that a formula defined by an `equal-style variable` can use the current timestep, elapsed time in the current run, elapsed time since the beginning of a series of runs, as well as access other variables.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

For atom type pairs IJ and I $\neq$ J, the A coefficient and cutoff distance for this pair style can be mixed. A is always mixed via a geometric rule. The cutoff is mixed according to the `pair_modify mix` value. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the `pair_modify` shift option, since the pair interaction goes to 0.0 at the cutoff.

The `pair_modify table` and `tail` options are not relevant for this pair style.

This pair style writes its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

18.409.5 Related commands
pair_coeff, pair_sph/rhosum

Default: none

18.410 pair_style spin/dipole/cut command

18.411 pair_style spin/dipole/long command

18.411.1 Syntax

pair_style spin/dipole/cut cutoff
pair_style spin/dipole/long cutoff

• cutoff = global cutoff for magnetic dipole energy and forces (optional) (distance units)

18.411.2 Examples

pair_style spin/dipole/cut 10.0
pair_coeff * * 10.0
pair_coeff 2 3 8.0

pair_style spin/dipole/long 9.0
pair_coeff * * 10.0
pair_coeff 2 3 6.0
18.411.3 Description

Style spin/dipole/cut computes a short-range dipole-dipole interaction between pairs of magnetic particles that each have a magnetic spin. The magnetic dipole-dipole interactions are computed by the following formulas for the magnetic energy, magnetic precession vector omega and mechanical force between particles I and J.

\[
\mathcal{H}_{\text{long}} = -\frac{\mu_0}{4\pi} \sum_{i,j,i\neq j}^N \frac{g_i g_j}{r_{ij}^3} \left(3 (\vec{e}_{ij} \cdot \vec{s}_i) (\vec{e}_{ij} \cdot \vec{s}_j) - \vec{s}_i \cdot \vec{e}_{ij} \vec{s}_j \right)
\]

\[
\omega_i = \frac{\mu_0 (\mu_B)^2}{4\pi \hbar} \sum_j \frac{g_i g_j}{r_{ij}^3} \left(3 (\vec{e}_{ij} \cdot \vec{s}_j) \vec{e}_{ij} - \vec{s}_j \right)
\]

\[
\vec{F}_i = \frac{3 \mu_0 (\mu_B)^2}{4\pi} \sum_j \frac{g_i g_j}{r_{ij}^4} \left[ ((\vec{s}_i \cdot \vec{s}_j) - 5(\vec{e}_{ij} \cdot \vec{s}_i)(\vec{e}_{ij} \cdot \vec{s}_j)) \vec{e}_{ij} + ((\vec{e}_{ij} \cdot \vec{s}_i) \vec{s}_j + (\vec{e}_{ij} \cdot \vec{s}_j) \vec{s}_i) \right]
\]

where \(\vec{s}_i\) and \(\vec{s}_j\) are the spin on two magnetic particles, \(r\) is their separation distance, and the vector \(\vec{e}_{ij} = \frac{r_i - r_j}{|r_i - r_j|}\) is the direction vector between the two particles.

Style spin/dipole/long computes long-range magnetic dipole-dipole interaction. A kspace_style must be defined to use this pair style. Currently, kspace_style ewald/dipole/spin and kspace_style pppm/dipole/spin support long-range magnetic dipole-dipole interactions.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

18.411.4 Restrictions

The spin/dipole/cut and spin/dipole/long styles are part of the SPIN package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Using dipole/spin pair styles with electron units is not currently supported.

18.411.5 Related commands

pair_coeff, kspace_style fix nve/spin

Default: none

18.412 pair_style spin/dmi command

18.412.1 Syntax

pair_style spin/dmi cutoff

• cutoff = global cutoff pair (distance in metal units)
18.412.2 Examples

```
pair_style spin/dmi 4.0
pair_coeff * * dmi 2.6 0.001 1.0 0.0 0.0
pair_coeff 1 2 dmi 4.0 0.00109 0.0 0.0 1.0
```

18.412.3 Description

Style `spin/dmi` computes the Dzyaloshinskii-Moriya (DM) interaction between pairs of magnetic spins. According to the expression reported in (Rohart), one has the following DM energy:

\[
H_{dm} = \sum_{i,j=1, i \neq j}^{N} \left( \vec{e}_{ij} \times \vec{D} \right) \cdot (\vec{s}_i \times \vec{s}_j),
\]

where \( \vec{s}_i \) and \( \vec{s}_j \) are two neighboring magnetic spins of two particles, \( \vec{e}_{ij} = \frac{\vec{r}_i - \vec{r}_j}{|\vec{r}_i - \vec{r}_j|} \) is the unit vector between sites \( i \) and \( j \), and \( \vec{D} \) is the DM vector defining the intensity (in eV) and the direction of the interaction.

In (Rohart), \( \vec{D} \) is defined as the direction normal to the film oriented from the high spin-orbit layer to the magnetic ultra-thin film.

The application of a spin-lattice Poisson bracket to this energy (as described in (Tranchida)) allows to derive a magnetic torque \( \vec{\omega} \), and a mechanical force \( \vec{F} \) (for spin-lattice calculations only) for each magnetic particle \( i \):

\[
\vec{\omega}_i = -\frac{1}{\hbar} \sum_{j}^{N_{\text{Neigh}}} \vec{s}_j \times \left( \vec{e}_{ij} \times \vec{D} \right) \quad \text{and} \quad \vec{F}_i = -\sum_{j}^{N_{\text{Neigh}}} \frac{1}{r_{ij}} \vec{D} \times (\vec{s}_i \times \vec{s}_j)
\]

More details about the derivation of these torques/forces are reported in (Tranchida).

For the `spin/dmi` pair style, the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, and set in the following order:

- \( \text{rc} \) (distance units)
- \( |D| \) (energy units)
- \( Dx, Dy, Dz \) (direction of \( D \))

Note that \( \text{rc} \) is the radius cutoff of the considered DM interaction, \( |D| \) is the norm of the DM vector (in eV), and \( Dx, Dy \) and \( Dz \) define its direction.

None of those coefficients is optional. If not specified, the `spin/dmi` pair style cannot be used.

18.412.4 Restrictions

All the `pair/spin` styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom_style “spin” was declared. See the `Build package` doc page for more info.
18.412.5 Related commands

atom_style spin, pair_coeff, pair_eam,

**Default:** none

18.413 pair_style spin/exchange command

18.413.1 Syntax

```
pair_style spin/exchange cutoff
```

- cutoff = global cutoff pair (distance in metal units)

18.413.2 Examples

```
pair_style spin/exchange 4.0
pair_coeff * * exchange 4.0 0.0446928 0.003496 1.4885
pair_coeff 1 2 exchange 6.0 -0.01575 0.0 1.965
```

18.413.3 Description

Style `spin/exchange` computes the exchange interaction between pairs of magnetic spins:

\[ H_{ex} = -\sum_{i,j}^N J_{ij}(r_{ij}) \vec{s}_i \cdot \vec{s}_j \]

where \( \vec{s}_i \) and \( \vec{s}_j \) are two neighboring magnetic spins of two particles, \( r_{ij} = |r_i - r_j| \) is the inter-atomic distance between the two particles. The summation is over pairs of nearest neighbors. \( J(r_{ij}) \) is a function defining the intensity and the sign of the exchange interaction for different neighboring shells. This function is defined as:

\[ J(r_{ij}) = 4a \left( \frac{r_{ij}}{d} \right)^2 \left( 1 - b \left( \frac{r_{ij}}{d} \right)^2 \right) e^{-\left( \frac{r_{ij}}{d} \right)^2} \Theta(R_c - r_{ij}) \]

where \( a, b, \) and \( d \) are the three constant coefficients defined in the associated “pair_coeff” command, and \( R_c \) is the radius cutoff associated to the pair interaction (see below for more explanations).

The coefficients \( a, b, \) and \( d \) need to be fitted so that the function above matches with the value of the exchange interaction for the \( N \) neighbor shells taken into account. Examples and more explanations about this function and its parameterization are reported in (Tranchida).

From this exchange interaction, each spin \( i \) will be submitted to a magnetic torque \( \vec{\omega}_i \), and its associated atom can be submitted to a force \( \vec{F} \) for spin-lattice calculations (see fix nve/spin), such as:

\[ \vec{\omega}_i = \frac{1}{\hbar} \sum_j^{Neigh} J(r_{ij}) \vec{s}_j \quad \text{and} \quad \vec{F}_i = \sum_j^{Neigh} \frac{\partial J(r_{ij})}{\partial r_{ij}} (\vec{s}_i \cdot \vec{s}_j) \vec{e}_{ij} \]
with $\hbar$ the Planck constant (in metal units), and $\vec{e}_{ij} = \frac{\vec{r}_i - \vec{r}_j}{|\vec{r}_i - \vec{r}_j|}$ the unit vector between sites $i$ and $j$.

More details about the derivation of these torques/forces are reported in (Tranchida).

For the spin/exchange pair style, the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, and set in the following order:

- $R_c$ (distance units)
- $a$ (energy units)
- $b$ (adim parameter)
- $d$ (distance units)

Note that $R_c$ is the radius cutoff of the considered exchange interaction, and $a$, $b$ and $d$ are the three coefficients performing the parameterization of the function $J(r_{ij})$ defined above.

None of those coefficients is optional. If not specified, the spin/exchange pair style cannot be used.

### 18.413.4 Restrictions

All the pair/spin styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the `atom_style` “spin” was declared. See the `Build package` doc page for more info.

pair_style spin/magelec 4.5
pair_coeff * * magelec 4.5 0.00109 1.0 1.0 1.0
```

18.414.3 Description

Style `spin/me` computes a magneto-electric interaction between pairs of magnetic spins. According to the derivation reported in (Katsura), this interaction is defined as:

\[
\vec{\omega}_i = -\frac{1}{\hbar} \sum_j \vec{s}_j \times \vec{D}(r_{ij})
\]

\[
\vec{F}_i = -\sum_j \left( \frac{\partial D(r_{ij})}{\partial r_{ij}} \right) \vec{s}_i \times \vec{E} \cdot \vec{r}_{ij}
\]

where \(\vec{s}_i\) and \(\vec{s}_j\) are neighboring magnetic spins of two particles.

From this magneto-electric interaction, each spin \(i\) will be submitted to a magnetic torque \(\vec{\omega}\), and its associated atom can be submitted to a force \(\vec{F}\) for spin-lattice calculations (see `fix nve/spin`), such as:

\[
\vec{F}_i = -\sum_j \left( \vec{s}_i \times \vec{s}_j \right) \times \vec{E}
\]

\[
\vec{\omega}_i = -\frac{1}{\hbar} \sum_j \vec{s}_j \times \left( \vec{E} \times \vec{r}_{ij} \right)
\]

where \(\hbar\) the Planck constant (in metal units) and \(\vec{E}\) an electric polarization vector. The norm and direction of \(\vec{E}\) are giving the intensity and the direction of a screened dielectric atomic polarization (in eV).

More details about the derivation of these torques/forces are reported in (Tranchida).

18.414.4 Restrictions

All the `pair/spin` styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the `atom_style` “spin” was declared. See the `Build package` doc page for more info.

18.414.5 Related commands

`atom_style spin`, `pair_coeff`, `pair_style spin/exchange`, `pair_eam`,

Default: none

18.415 pair_style spin/neel command

18.415.1 Syntax

```
pair_style spin/neel cutoff
```

- cutoff = global cutoff pair (distance in metal units)

18.415.2 Examples

```
pair_style spin/neel 4.0
pair_coeff * * neel 4.0 0.0048 0.234 1.168 2.6905 0.705 0.652
pair_coeff 1 2 neel 4.0 0.0048 0.234 1.168 0.0 0.0 1.0
```

18.415.3 Description

Style spin/neel computes the Neel pair anisotropy model between pairs of magnetic spins:

\[ H_{\text{Neel}} = - \sum_{i,j=1,i\neq j}^{N} g_1(r_{ij}) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_i)(\mathbf{e}_{ij} \cdot \mathbf{s}_j) - \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{3} \right) + q_1(r_{ij}) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_i)^2 - \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{3} \right) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_j)^2 - \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{3} \right) + q_2(r_{ij}) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_i)^2 - \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{3} \right) + q_2(r_{ij}) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_j)^2 - \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{3} \right) \]

where \( \mathbf{s}_i \) and \( \mathbf{s}_j \) are two neighboring magnetic spins of two particles, \( r_{ij} = |\mathbf{r}_i - \mathbf{r}_j| \) is the inter-atomic distance between the two particles, \( \mathbf{e}_{ij} = \frac{\mathbf{r}_i - \mathbf{r}_j}{|\mathbf{r}_i - \mathbf{r}_j|} \) is their normalized separation vector and \( g_1, q_1 \) and \( q_2 \) are three functions defining the intensity of the dipolar and quadrupolar contributions, with:

\[
g_1(r_{ij}) = g(r_{ij}) + \frac{12}{35} q(r_{ij})
\]

\[
q_1(r_{ij}) = \frac{9}{5} q(r_{ij})
\]

\[
q_2(r_{ij}) = -\frac{2}{5} q(r_{ij})
\]

With the functions \( g(r_{ij}) \) and \( q(r_{ij}) \) defined and fitted according to the same Bethe-Slater function used to fit the exchange interaction:

\[
J(r_{ij}) = 4a \left( \frac{r_{ij}}{d} \right)^2 \left( 1 - b \left( \frac{r_{ij}}{d} \right)^2 \right) e^{-\left( \frac{r_{ij}}{d} \right)^2} \Theta(R_c - r_{ij})
\]

where \( a, b, \) and \( d \) are the three constant coefficients defined in the associated “pair_coeff” command.

The coefficients \( a, b, \) and \( d \) need to be fitted so that the function above matches with the values of the magneto-elastic constant of the materials at stake.

Examples and more explanations about this function and its parameterization are reported in (Tranchida). More examples of parameterization will be provided in future work.

From this DM interaction, each spin \( i \) will be submitted to a magnetic torque \( \omega \) and its associated atom to a force \( F \) (for spin-lattice calculations only).

More details about the derivation of these torques/forces are reported in (Tranchida).
18.415.4 Restrictions

All the pair/spin styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom_style “spin” was declared. See the Build package doc page for more info.

\end{verbatim}
18.416.3 Description

Style srp computes a soft segmental repulsive potential (SRP) that acts between pairs of bonds. This potential is useful for preventing bonds from passing through one another when a soft non-bonded potential acts between beads in, for example, DPD polymer chains. An example input script that uses this command is provided in examples/USER/srp.

Bonds of specified type btype interact with one another through a bond-pairwise potential, such that the force on bond $i$ due to bond $j$ is as follows

$$F_{ij}^{SRP} = C(1 - r/r_c)\hat{r}_{ij} \quad r < r_c$$

where $r$ and $\hat{r}_{ij}$ are the distance and unit vector between the two bonds. Note that btype can be specified as an asterisk "*", which case the interaction is applied to all bond types. The mid option computes $r$ and $\hat{r}_{ij}$ from the midpoint distance between bonds. The min option computes $r$ and $\hat{r}_{ij}$ from the minimum distance between bonds. The force acting on a bond is mapped onto the two bond atoms according to the lever rule,

$$F_{i1}^{SRP} = F_{ij}^{SRP} (L)$$
$$F_{i2}^{SRP} = F_{ij}^{SRP} (1 - L)$$

where $L$ is the normalized distance from the atom to the point of closest approach of bond $i$ and $j$. The mid option takes $L$ as 0.5 for each interaction as described in (Sirk).

The following coefficients must be defined via the pair_coeff command as in the examples above, or in the data file or restart file read by the read_data or read_restart commands:

- $C$ (force units)
- $r_c$ (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

Note: Pair style srp considers each bond of type btype to be a fictitious “particle” of type bptype, where bptype is either the largest atom type in the system, or the type set by the bptype flag. Any actual existing particles with this atom type will be deleted at the beginning of a run. This means you must specify the number of types in your system accordingly; usually to be one larger than what would normally be the case, e.g. via the create_box or by changing the header in your data file. The fictitious “bond particles” are inserted at the beginning of the run, and serve as placeholders that define the position of the bonds. This allows neighbor lists to be constructed and pairwise interactions to be computed in almost the same way as is done for actual particles. Because bonds interact only with other bonds, pair_style hybrid should be used to turn off interactions between atom type bptype and all other types of atoms. An error will be flagged if pair_style hybrid is not used.

The optional exclude keyword determines if forces are computed between first neighbor (directly connected) bonds. For a setting of no, first neighbor forces are computed; for yes they are not computed. A setting of no cannot be used with the min option for distance calculation because the minimum distance between directly connected bonds is zero.

Pair style srp turns off normalization of thermodynamic properties by particle number, as if the command thermo_modify norm no had been issued.

The pairwise energy associated with style srp is shifted to be zero at the cutoff distance $r_c$.

Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support mixing.

This pair style does not support the pair_modify shift option for the energy of the pair interaction. Note that as discussed above, the energy term is already shifted to be 0.0 at the cutoff distance $r_c$. 

18.416. pair_style srp command
The *pair_modify* table option is not relevant for this pair style.

This pair style does not support the *pair_modify* tail option for adding long-range tail corrections to energy and pressure.

This pair style writes global and per-atom information to binary restart files. Pair srp should be used with *pair_style hybrid*, thus the pair_coeff commands need to be specified in the input script when reading a restart file.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner, middle, outer* keywords.

### 18.416.4 Restrictions

This pair style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Making LAMMPS section for more info.

This pair style must be used with *pair_style hybrid*.

This pair style requires the *newton* command to be *on* for non-bonded interactions.

This pair style is not compatible with *rigid body integrators*.

18.421.3 Description

The `sw` style computes a 3-body Stillinger-Weber potential for the energy $E$ of a system of atoms as

$$E = \sum_i \sum_{j>i} \phi_2(r_{ij}) + \sum_i \sum_{j \neq i} \sum_{k > j} \phi_3(r_{ij}, r_{ik}, \theta_{ijk})$$

$$\phi_2(r_{ij}) = A_{ij} \varepsilon_{ij} \left[ B_{ij} \left( \frac{\sigma_{ij}}{r_{ij}} \right)^{p_{ij}} - \left( \frac{\sigma_{ij}}{r_{ij}} \right)^{q_{ij}} \right] \exp \left( \frac{\sigma_{ij}}{r_{ij} - a_{ij} \sigma_{ij}} \right)$$

$$\phi_3(r_{ij}, r_{ik}, \theta_{ijk}) = \lambda_{ijk} \varepsilon_{ijk} \left[ \cos \theta_{ijk} - \cos \theta_{bijk} \right] \exp \left( \frac{\gamma_{ij} \sigma_{ij}}{r_{ij} - a_{ij} \sigma_{ij}} \right) \exp \left( \frac{\gamma_{ik} \sigma_{ik}}{r_{ik} - a_{ik} \sigma_{ik}} \right)$$

where $\phi_2$ is a two-body term and $\phi_3$ is a three-body term. The summations in the formula are over all neighbors $J$ and $K$ of atom $I$ within a cutoff distance $a$.

Only a single `pair_coeff` command is used with the `sw` style which specifies a Stillinger-Weber potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying $N$ additional arguments after the filename in the `pair_coeff` command, where $N$ is the number of LAMMPS atom types:

- `filename`
- $N$ element names = mapping of SW elements to atom types

See the `pair_coeff` doc page for alternate ways to specify the path for the potential file.

As an example, imagine a file `SiC.sw` has Stillinger-Weber values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following `pair_coeff` command:

```plaintext
pair_coeff * * SiC.sw Si Si Si C
```

The first 2 arguments must be `* *` so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the SW file. The final C argument maps LAMMPS atom type 4 to the C element in the SW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a `sw` potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Stillinger-Weber files in the `potentials` directory of the LAMMPS distribution have a “.sw” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- $\varepsilon$ (energy units)
- $\sigma$ (distance units)
- $a$
- $\lambda$
- $\gamma$
• $\cos \theta_0$
• A
• B
• p
• q
• tol

The A, B, p, and q parameters are used only for two-body interactions. The $\lambda$ and $\cos \theta_0$ parameters are used only for three-body interactions. The $\epsilon$, $\sigma$ and $a$ parameters are used for both two-body and three-body interactions. $\gamma$ is used only in the three-body interactions, but is defined for pairs of atoms. The non-annotated parameters are unitless.

LAMMPS introduces an additional performance-optimization parameter tol that is used for both two-body and three-body interactions. In the Stillinger-Weber potential, the interaction energies become negligibly small at atomic separations substantially less than the theoretical cutoff distances. LAMMPS therefore defines a virtual cutoff distance based on a user defined tolerance tol. The use of the virtual cutoff distance in constructing atom neighbor lists can significantly reduce the neighbor list sizes and therefore the computational cost. LAMMPS provides a tol value for each of the three-body entries so that they can be separately controlled. If tol = 0.0, then the standard Stillinger-Weber cutoff is used.

The Stillinger-Weber potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries. For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify SW parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction. Thus an entry for SiCC means a Si atom with 2 C atoms as neighbors. The parameter values used for the two-body interaction come from the entry where the second and third elements are the same. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry. The three-body parameters can in principle be specific to the three elements of the configuration. In the literature, however, the three-body parameters are usually defined by simple formulas involving two sets of pair-wise parameters, corresponding to the ij and ik pairs, where i is the center atom. The user must ensure that the correct combining rule is used to calculate the values of the three-body parameters for alloys. Note also that the function $\phi_3$ contains two exponential screening factors with parameter values from the ij pair and ik pairs. So $\phi_3$ for a C atom bonded to a Si atom and a second C atom will depend on the three-body parameters for the CSiC entry, and also on the two-body parameters for the CCC and CCSI entries. Since the order of the two neighbors is arbitrary, the three-body parameters for entries CSiC and CCSi should be the same. Similarly, the two-body parameters for entries SiCC and CCSI should also be the same. The parameters used only for two-body interactions (A, B, p, and q) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired. This is also true for the parameters in $\phi_3$ that are taken from the ij and ik pairs ($\sigma$, $a$, $\gamma$)

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.
When using the USER-INTEL package with this style, there is an additional 5 to 10 percent performance improvement when the Stillinger-Weber parameters p and q are set to 4 and 0 respectively. These parameters are common for modeling silicon and water.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

18.421.4 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The Stillinger-Weber potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the SW potential with any LAMMPS units, but you would need to create your own SW potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

pair_style table linear 1000 pppm
pair_style table bitmap 12
pair_coeff * 3 morse.table ENTRY1
pair_coeff * 3 morse.table ENTRY1 7.0
```

18.425.3 Description

Style *table* creates interpolation tables from potential energy and force values listed in a file(s) as a function of distance. When performing dynamics or minimization, the interpolation tables are used to evaluate energy and forces for pairwise interactions between particles, similar to how analytic formulas are used for other pair styles.

The interpolation tables are created as a pre-computation by fitting cubic splines to the file values and interpolating energy and force values at each of **N** distances. During a simulation, the tables are used to interpolate energy and force values as needed for each pair of particles separated by a distance **R**. The interpolation is done in one of 4 styles: *lookup*, *linear*, *spline*, or *bitmap*.

For the *lookup* style, the distance **R** is used to find the nearest table entry, which is the energy or force.

For the *linear* style, the distance **R** is used to find the 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the *spline* style, a cubic spline coefficients are computed and stored for each of the **N** values in the table, one set of splines for energy, another for force. Note that these splines are different than the ones used to pre-compute the **N** values. Those splines were fit to the **Nfile** values in the tabulated file, where often **Nfile** < **N**. The distance **R** is used to find the appropriate set of spline coefficients which are used to evaluate a cubic polynomial which computes the energy or force.
For the `bitmap` style, the specified $N$ is used to create interpolation tables that are $2^N$ in length. The distance $R$ is used to index into the table via a fast bit-mapping technique due to (Wolff), and a linear interpolation is performed between adjacent table values.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above.

- `filename`
- `keyword`
- `cutoff` (distance units)

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

If your tabulated potential(s) are designed to be used as the short-range part of one of the long-range solvers specified by the `kspace_style` command, then you must use one or more of the optional keywords listed above for the `pair_style` command. These are `ewald` or `pppm` or `msm` or `dispersion` or `tip4p`. This is so LAMMPS can insure the short-range potential and long-range solver are compatible with each other, as it does for other short-range pair styles, such as `pair_style lj/cut/coul/long`. Note that it is up to you to insure the tabulated values for each pair of atom types has the correct functional form to be compatible with the matching long-range solver.

Here are some guidelines for using the `pair_style table` command to best effect:

- Vary the number of table points; you may need to use more than you think to get good resolution.
- Always use the `pair_write` command to produce a plot of what the final interpolated potential looks like. This can show up interpolation “features” you may not like.
- Start with the linear style; it’s the style least likely to have problems.
- Use $N$ in the `pair_style` command equal to the “N” in the tabulation file, and use the “RSQ” or “BITMAP” parameter, so additional interpolation is not needed. See discussion below.
- Make sure that your tabulated forces and tabulated energies are consistent (dE/dr = -F) over the entire range of $r$ values. LAMMPS will warn if this is not the case.
- Use as large an inner cutoff as possible. This avoids fitting splines to very steep parts of the potential.

The format of a tabulated file has an (optional) header followed by a series of one or more sections, defined as follows (without the parenthesized comments). The header must start with a # character and the DATE: and UNITS: tags will be parsed and used:

```
# DATE: 2020-06-10  UNITS: real    CONTRIBUTOR: ... (header line)
# Morse potential for Fe    (one or more comment or blank lines)
MORSE_FE
N 500 R 1.0 10.0                  (keyword is first text on line)
(N, R, RSQ, BITMAP, FPRIME parameters)
(blank)
1 1.0 25.5 102.34               (index, r, energy, force)
2 1.02 23.4 98.5
...                             
500 10.0 0.001 0.003
```
A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the pair_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the pair_style table command. Let Ntable = N in the pair_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate energy and force values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and force for individual pair distances. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile, and use the “RSQ” or “BITMAP” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” or “BITMAP” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in r uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values rlo and rhi. If specified, the distance associated with each energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The distance values in the table file are ignored in this case. For “R”, distances uniformly spaced between rlo and rhi are computed; for “RSQ”, squared distances uniformly spaced between rlo*rlo and rhi*rhi are computed.

Note: If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the distance value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning energy/force values to a different distance, which is probably not what you want. LAMMPS will warn if this is occurring.

If used, the parameter “BITMAP” is also followed by 2 values rlo and rhi. These values, along with the “N” value determine the ordering of the N lines that follow and what distance is associated with each. This ordering is complex, so it is not documented here, since this file is typically produced by the pair_write command with its bitmap option. When the table is in BITMAP format, the “N” parameter in the file must be equal to 2^M where M is the value specified in the pair_style command. Also, a cutoff parameter cannot be used as an optional third argument in the pair_coeff command; the entire table extent as specified in the file must be used.

If used, the parameter “FPRIME” is followed by 2 values fplo and fphi which are the derivative of the force at the innermost and outermost distances listed in the table. These values are needed by the spline construction routines. If not specified by the “FPRIME” parameter, they are estimated (less accurately) by the first 2 and last 2 force values in the table. This parameter is not used by BITMAP tables.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The r values must increase from one line to the next (unless the BITMAP parameter is specified).

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

### Mixing, shift, table, tail correction, restart, rRESPA info:

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The `pair_modify` shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair_style table” command to `binary restart files`, so a pair_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, pair_coeff commands do need to be specified in the restart input script.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

18.427.3 Description

Style table/rx is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of \( m \) species whose reaction rate kinetics are determined from a set of \( n \) reaction rate equations through the fix rx command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. Style table/rx creates interpolation tables of length \( N \) from pair potential and force values listed in a file(s) as a function of distance. The files are read by the pair_coeff command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and force values at each of \( N \) distances. During a simulation, these tables are used to interpolate energy and force values as needed. The interpolation is done in one of 4 styles: lookup, linear, spline, or bitmap.

For the lookup style, the distance between 2 atoms is used to find the nearest table entry, which is the energy or force.

For the linear style, the pair distance is used to find 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the spline style, a cubic spline coefficients are computed and stored at each of the \( N \) values in the table. The pair distance is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

For the bitmap style, the \( N \) means to create interpolation tables that are \( 2^N \) in length. The pair distance is used to index into the table via a fast bit-mapping technique (Wolff) and a linear interpolation is performed between adjacent table values.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above.

- filename
- keyword
- species1
- species2
- cutoff (distance units)

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The species tags define the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the fix rx command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the fractional or molecular weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).
Here are some guidelines for using the `pair_style table/rx` command to best effect:

- Vary the number of table points; you may need to use more than you think to get good resolution.
- Always use the `pair_write` command to produce a plot of what the final interpolated potential looks like. This can show up interpolation “features” you may not like.
- Start with the linear style; it’s the style least likely to have problems.
- Use N in the `pair_style` command equal to the “N” in the tabulation file, and use the “RSQ” or “BITMAP” parameter, so additional interpolation is not needed. See discussion below.
- Make sure that your tabulated forces and tabulated energies are consistent (dE/dr = -F) along the entire range of r values.
- Use as large an inner cutoff as possible. This avoids fitting splines to very steep parts of the potential.

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

```plaintext
# Morse potential for Fe   (one or more comment or blank lines)

MORSE_FE                 (keyword is first text on line)
N 500 R 1.0 10.0          (N, R, RSQ, BITMAP, FPRIME parameters)
    (blank)
  1 1.0 25.5 102.34       (index, r, energy, force)
  2 1.02 23.4 98.5
  ...
  500 10.0 0.001 0.003
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the `pair_coeff` command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the `pair_style table/rx` command. Let Ntable = N in the `pair_style` command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and force values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and force for individual pair distances. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile, and use the “RSQ” or “BITMAP” parameter. The internal table abscissa is RSQ (separation distance squared).

All other parameters are optional. If “R” or “RSQ” or “BITMAP” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in r uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values rlo and rhi. If specified, the distance associated with each energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The distance values in the table file are ignored in this case. For “R”, distances uniformly spaced between rlo and rhi are computed; for “RSQ”, squared distances uniformly spaced between rlo*rlo and rhi*rhi are computed.

If used, the parameter “BITMAP” is also followed by 2 values rlo and rhi. These values, along with the “N” value determine the ordering of the N lines that follow and what distance is associated with each. This ordering is complex,
so it is not documented here, since this file is typically produced by the `pair_write` command with its `bitmap` option. When the table is in BITMAP format, the “N” parameter in the file must be equal to $2^M$ where M is the value specified in the `pair_style` command. Also, a cutoff parameter cannot be used as an optional third argument in the `pair_coeff` command; the entire table extent as specified in the file must be used.

If used, the parameter “FPRIME” is followed by 2 values $fplo$ and $fphi$ which are the derivative of the force at the innermost and outermost distances listed in the table. These values are needed by the spline construction routines. If not specified by the “FPRIME” parameter, they are estimated (less accurately) by the first 2 and last 2 force values in the table. This parameter is not used by BITMAP tables.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The r values must increase from one line to the next (unless the BITMAP parameter is specified).

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The `pair_modify` shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair_style table/rx” command to binary restart files, so a pair_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, `pair_coeff` commands do need to be specified in the restart input script.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

**18.427.4 Restrictions**

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.434.3 Description

The *tersoff* style computes a 3-body Tersoff potential (*Tersoff_I*) for the energy $E$ of a system of atoms as

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = f_C(r_{ij})\left[f_R(r_{ij}) + b_{ij} f_A(r_{ij})\right]$$

$$f_C(r) = \begin{cases} 
1 & : r < R - D \\
\frac{1}{2} - \frac{1}{2} \sin \left(\frac{\pi}{2} \frac{r - R}{D}\right) & : R - D < r < R + D \\
0 & : r > R + D 
\end{cases}$$

$$f_R(r) = A \exp(-\lambda_1 r)$$

$$f_A(r) = -B \exp(-\lambda_2 r)$$

$$b_{ij} = (1 + \beta^n \zeta_{ij}^n)^{-\frac{1}{n}}$$

$$\zeta_{ij} = \sum_{k \neq i,j} f_C(r_{ik}) g(\theta_{ijk}) \exp\left[\lambda_3^m (r_{ij} - r_{ik})^m\right]$$

$$g(\theta) = \gamma_{ijk} \left(1 + \frac{c^2}{d^2} - \frac{c^2}{d^2 + (\cos \theta - \cos \theta_0)^2}\right)$$

where $f_R$ is a two-body term and $f_A$ includes three-body interactions. The summations in the formula are over all neighbors $J$ and $K$ of atom $I$ within a cutoff distance $= R + D$.

The *tersoff/table* style uses tabulated forms for the two-body, environment and angular functions. Linear interpolation is performed between adjacent table entries. The table length is chosen to be accurate within $10^{-6}$ with respect to the *tersoff* style energy. The *tersoff/table* should give better performance in terms of speed.

Only a single pair_coeff command is used with the *tersoff* style which specifies a Tersoff potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying $N$ additional arguments after the filename in the pair_coeff command, where $N$ is the number of LAMMPS atom types:

- filename
- $N$ element names = mapping of Tersoff elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, imagine the SiC.tersoff file has Tersoff values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * SiC.tersoff Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff file. The final C argument maps LAMMPS atom type 4 to the C element in the Tersoff file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *tersoff* potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Tersoff files in the potentials directory of the LAMMPS distribution have a “.tersoff” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- $m$
• $\gamma$
• $\lambda_3$ (1/distance units)
• $c$
• $d$
• $\cos \theta_0$ (can be a value $<-1$ or $>1$)
• $n$
• $\beta$
• $\lambda_2$ (1/distance units)
• $B$ (energy units)
• $R$ (distance units)
• $D$ (distance units)
• $\lambda_1$ (1/distance units)
• $A$ (energy units)

The $n$, $\beta$, $\lambda_2$, $B$, $\lambda_1$, and $A$ parameters are only used for two-body interactions. The $m$, $\gamma$, $\lambda_3$, $c$, $d$, and $\cos \theta_0$ parameters are only used for three-body interactions. The $R$ and $D$ parameters are used for both two-body and three-body interactions. The non-annotated parameters are unitless. The value of $m$ must be 3 or 1.

The Tersoff potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCiSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify Tersoff parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiCC means Si bonded to a C with another C atom influencing the bond. Thus three-body parameters for SiSi and SiCi entries will not, in general, be the same. The parameters used for the two-body interaction come from the entry where the second element is repeated. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry.

The parameters used for a particular three-body interaction come from the entry with the corresponding three elements. The parameters used only for two-body interactions ($n$, $\beta$, $\lambda_2$, $B$, $\lambda_1$, and $A$) in entries whose second and third element are different (e.g. SiCsi) are not used for anything and can be set to 0.0 if desired.

Note that the two-body parameters in entries such as SiCC and CSiSi are often the same, due to the common use of symmetric mixing rules, but this is not always the case. For example, the beta and $n$ parameters in Tersoff_2 (Tersoff_2) are not symmetric.

We chose the above form so as to enable users to define all commonly used variants of the Tersoff potential. In particular, our form reduces to the original Tersoff form when $m = 3$ and gamma = 1, while it reduces to the form of Albe et al. when beta = 1 and $m = 1$. Note that in the current Tersoff implementation in LAMMPS, $m$ must be specified as either 3 or 1. Tersoff used a slightly different but equivalent form for alloys, which we will refer to as Tersoff_2 potential (Tersoff_2). The tersoff/table style implements Tersoff_2 parameterization only.

LAMMPS parameter values for Tersoff_2 can be obtained as follows: $\gamma_{ijk} = \omega_{ik}$, $\lambda_3 = 0$ and the value of $m$ has no
effect. The parameters for species i and j can be calculated using the Tersoff_2 mixing rules:

\[ \lambda_{i,j}^{1} = \frac{1}{2}(\lambda_{i}^{1} + \lambda_{j}^{1}) \]

\[ \lambda_{i,j}^{2} = \frac{1}{2}(\lambda_{i}^{2} + \lambda_{j}^{2}) \]

\[ A_{i,j} = (A_{i}A_{j})^{1/2} \]

\[ B_{i,j} = \chi_{ij}(B_{i}B_{j})^{1/2} \]

\[ R_{i,j} = (R_{i}R_{j})^{1/2} \]

\[ S_{i,j} = (S_{i}S_{j})^{1/2} \]

Tersoff_2 parameters R and S must be converted to the LAMMPS parameters R and D (R is different in both forms), using the following relations: \( R = (R' + S')/2 \) and \( D = (S' - R')/2 \), where the primes indicate the Tersoff_2 parameters.

In the potentials directory, the file SiCGe.tersoff provides the LAMMPS parameters for Tersoff’s various versions of Si, as well as his alloy parameters for Si, C, and Ge. This file can be used for pure Si, (three different versions), pure C, pure Ge, binary SiC, and binary SiGe. LAMMPS will generate an error if this file is used with any combination involving C and Ge, since there are no entries for the GeC interactions (Tersoff did not publish parameters for this cross-interaction.) Tersoff files are also provided for the SiC alloy (SiC.tersoff) and the GaN (GaN.tersoff) alloys.

Many thanks to Rutuparna Narulkar, David Farrell, and Xiaowang Zhou for helping clarify how Tersoff parameters for alloys have been defined in various papers.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

For atom type pairs I,J and I \(!= J\), where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the \textit{pair_modify} shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the \textit{pair} keyword of the \textit{run_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.
18.434.4 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The Tersoff potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the Tersoff potential with any LAMMPS units, but you would need to create your own Tersoff potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

18.440.3 Description

The `tersoff/mod` and `tersoff/mod/c` styles computes a bond-order type interatomic potential \((\text{Kumagai})\) based on a 3-body Tersoff potential \((\text{Tersoff}_1), (\text{Tersoff}_2)\) with modified cutoff function and angular-dependent term, giving the energy \(E\) of a system of atoms as

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}
\]

\[
V_{ij} = f_C(r_{ij}) [f_R(r_{ij}) + b_{ij} f_A(r_{ij})]
\]

\[
f_C(r) = \begin{cases} 
1 - \frac{3}{16} \sin \left( \frac{\pi}{2} \frac{r-R}{D} \right) - \frac{1}{16} \sin \left( \frac{3\pi}{2} \frac{r-R}{D} \right) & : r < R - D \\
\frac{1}{16} & : R - D < r < R + D \\
0 & : r > R + D
\end{cases}
\]

\[
f_R(r) = A \exp(-\lambda_1 r)
\]

\[
f_A(r) = -B \exp(-\lambda_2 r)
\]

\[
b_{ij} = (1 + \zeta_{ij} \eta)^{-\frac{1}{4}}
\]

\[
\zeta_{ij} = \sum_{k \neq i,j} f_C(r_{ik}) g(\theta_{ijk}) \exp \left[ \alpha(r_{ij} - r_{ik})^2 \right]
\]

\[
g(\theta) = c_1 + g_o(\theta) g_a(\theta)
\]

\[
g_o(\theta) = \frac{c_2 (h - \cos \theta)^2}{c_3 + (h - \cos \theta)^2}
\]

\[
g_a(\theta) = 1 + c_4 \exp \left[ -c_5 (h - \cos \theta)^2 \right]
\]

where \(f_R\) is a two-body term and \(f_A\) includes three-body interactions. The summations in the formula are over all neighbors J and K of atom I within a cutoff distance = \(R + D\). The `tersoff/mod/c` style differs from `tersoff/mod` only in the formulation of the \(V_{ij}\) term, where it contains an additional \(c_0\) term.

\[
V_{ij} = f_C(r_{ij}) [f_R(r_{ij}) + b_{ij} f_A(r_{ij}) + c_0]
\]

The modified cutoff function \(f_C\) proposed by \((\text{Murty})\) and having a continuous second-order differential is employed. The angular-dependent term \(g(\theta)\) was modified to increase the flexibility of the potential.

The `tersoff/mod` potential is fitted to both the elastic constants and melting point by employing the modified Tersoff potential function form in which the angular-dependent term is improved. The model performs extremely well in describing the crystalline, liquid, and amorphous phases \((\text{Schelling})\).

Only a single pair_coeff command is used with the `tersoff/mod` style which specifies a Tersoff/MOD potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying \(N\) additional arguments after the filename in the pair_coeff command, where \(N\) is the number of LAMMPS atom types:

- `filename`
- `N element names = mapping of Tersoff/MOD elements to atom types`

As an example, imagine the Si.tersoff_mod file has Tersoff values for Si. If your LAMMPS simulation has 3 Si atoms types, you would use the following pair_coeff command:
pair_coeff * * Si tersoff_mod Si Si Si

The first 2 arguments must be ** so as to span all LAMMPS atom types. The three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff/MOD file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a tersoff/mod potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Tersoff/MOD file in the potentials directory of the LAMMPS distribution have a “.tersoff.mod” suffix. Potential files for the tersoff/mod/c style have the suffix “.tersoff.modc”. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formulae above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- \( \beta \)
- \( \alpha \)
- \( h \)
- \( \eta \)
- \( \beta_{\text{ters}} = 1 \) (dummy parameter)
- \( \lambda_2 \) (1/distance units)
- \( B \) (energy units)
- \( R \) (distance units)
- \( D \) (distance units)
- \( \lambda_1 \) (1/distance units)
- \( A \) (energy units)
- \( n \)
- \( c_1 \)
- \( c_2 \)
- \( c_3 \)
- \( c_4 \)
- \( c_5 \)
- \( c_0 \) (energy units, tersoff/mod/c only):ul

The \( n, \eta, \lambda_2, B, \lambda_1, \) and A parameters are only used for two-body interactions. The \( \beta, \alpha, c_1, c_2, c_3, c_4, c_5, h \) parameters are only used for three-body interactions. The R and D parameters are used for both two-body and three-body interactions. The \( c_0 \) term applies to tersoff/mod/c only. The non-annotated parameters are unitless.

The Tersoff/MOD potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiSiSi means Si bonded to a Si with another Si atom influencing the bond.
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

---

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support the `pair_modify shift`, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

---

### 18.440.4 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

The Tersoff/MOD potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the Tersoff/MOD potential with any LAMMPS units, but you would need to create your own Tersoff/MOD potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

18.442 pair_style tersoff/zbl/gpu command

18.443 pair_style tersoff/zbl/kk command

18.444 pair_style tersoff/zbl/omp command

18.444.1 Syntax

```
pair_style tersoff/zbl
```

18.444.2 Examples

```
pair_style tersoff/zbl
pair_coeff * * SiC.tersoff.zbl Si C Si
```

18.444.3 Description

The `tersoff/zbl` style computes a 3-body Tersoff potential \((Tersoff_1)\) with a close-separation pairwise modification based on a Coulomb potential and the Ziegler-Biersack-Littmark universal screening function \((ZBL)\), giving the energy
E of a system of atoms as

\[ E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \]

\[ V_{ij} = (1 - f_F(r_{ij})) V_{ij}^{ZBL} + f_F(r_{ij}) V_{ij}^{Tersoff} \]

\[ f_F(r_{ij}) = \frac{1}{1 + e^{-A_F(r_{ij} - r_C)}} \]

\[ V_{ij}^{ZBL} = \frac{1}{4\pi\varepsilon_0} \frac{Z_1 Z_2 e^2}{r_{ij}} \phi(r_{ij}/a) \]

\[ a = \frac{0.8854 a_0}{Z_1^{0.24} + Z_2^{0.23}} \]

\[ \phi(x) = 0.1818 e^{-3.2x} + 0.5099 e^{-0.9423x} + 0.2802 e^{-0.4029x} + 0.02817 e^{-0.2016x} \]

\[ V_{ij}^{Tersoff} = f_C(r_{ij}) [f_R(r_{ij}) + b_{ij} f_A(r_{ij})] \]

\[ f_C(r) = \begin{cases} 1 & : r < R - D \\ \frac{1}{2} - \frac{1}{2} \sin \left( \frac{\pi (r - R)}{2(R - D)} \right) & : R - D < r < R + D \\ 0 & : r > R + D \end{cases} \]

\[ f_R(r) = A \exp(-\lambda_1 r) \]

\[ f_A(r) = -B \exp(-\lambda_2 r) \]

\[ b_{ij} = (1 + \beta^m \zeta_{ij}^n)^{-\frac{1}{n}} \]

\[ \zeta_{ij} = \sum_{k \neq i,j} f_C(r_{ik}) g(\theta_{ijk}) \exp \left[ \lambda_3^m (r_{ij} - r_{ik})^m \right] \]

\[ g(\theta) = \gamma_{ijk} \left( 1 + \frac{c^2}{d^2} - \frac{c^2}{(d^2 + (\cos \theta - \cos \theta_0)^2)} \right) \]

The \( f_F \) term is a fermi-like function used to smoothly connect the ZBL repulsive potential with the Tersoff potential. There are 2 parameters used to adjust it: \( A_F \) and \( r_C \). \( A_F \) controls how “sharp” the transition is between the two, and \( r_C \) is essentially the cutoff for the ZBL potential.

For the ZBL portion, there are two terms. The first is the Coulomb repulsive term, with \( Z_1 \), \( Z_2 \) as the number of protons in each nucleus, \( e \) as the electron charge (1 for metal and real units) and \( \varepsilon_0 \) as the permittivity of vacuum. The second part is the ZBL universal screening function, with \( a_0 \) being the Bohr radius (typically 0.529 Angstroms), and the remainder of the coefficients provided by the original paper. This screening function should be applicable to most systems. However, it is only accurate for small separations (i.e. less than 1 Angstrom).

For the Tersoff portion, \( f_R \) is a two-body term and \( f_A \) includes three-body interactions. The summations in the formula are over all neighbors \( J \) and \( K \) of atom \( I \) within a cutoff distance = \( R + D \).

Only a single pair_coeff command is used with the tersoff/zbl style which specifies a Tersoff/ZBL potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:

- \text{filename}
- \text{N element names} = mapping of Tersoff/ZBL elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, imagine the SiC.tersoff.zbl file has Tersoff/ZBL values for Si and C. If your LAMMPS simulation
has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```plaintext
pair_coeff * * SiC.tersoff Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff/ZBL file. The final C argument maps LAMMPS atom type 4 to the C element in the Tersoff/ZBL file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a tersoff/zbl potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Tersoff/ZBL files in the potentials directory of the LAMMPS distribution have a “.tersoff.zbl” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- m
- \( \gamma \)
- \( \lambda_3 \) (1/distance units)
- c
- d
- \( \cos \theta_0 \) (can be a value < -1 or > 1)
- n
- \( \beta \)
- \( \lambda_2 \) (1/distance units)
- B (energy units)
- R (distance units)
- D (distance units)
- \( \lambda_1 \) (1/distance units)
- A (energy units)
- \( Z_i \)
- \( Z_j \)
- ZBLcut (distance units)
- ZBLexpscale (1/distance units)

The n, \( \beta \), \( \lambda_2 \), B, \( \lambda_1 \), and A parameters are only used for two-body interactions. The m, \( \gamma \), \( \lambda_3 \), c, d, and \( \cos \theta_0 \) parameters are only used for three-body interactions. The R and D parameters are used for both two-body and three-body interactions. The \( Z_i \), \( Z_j \), ZBLcut, ZBLexpscale parameters are used in the ZBL repulsive portion of the potential and in the Fermi-like function. The non-annotated parameters are unitless. The value of m must be 3 or 1.

The Tersoff/ZBL potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSI, CCC), that specify Tersoff parameters for
all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiCC means Si bonded to a C with another C atom influencing the bond. Thus three-body parameters for SiCSi and SiSiC entries will not, in general, be the same. The parameters used for the two-body interaction come from the entry where the second element is repeated. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry.

The parameters used for a particular three-body interaction come from the entry with the corresponding three elements. The parameters used only for two-body interactions (n, β, λ2, B, λ1, and A) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired.

Note that the two-body parameters in entries such as SiCC and CSiSi are often the same, due to the common use of symmetric mixing rules, but this is not always the case. For example, the beta and n parameters in Tersoff_2 (Tersoff_2) are not symmetric.

We chose the above form so as to enable users to define all commonly used variants of the Tersoff portion of the potential. In particular, our form reduces to the original Tersoff form when m = 3 and gamma = 1, while it reduces to the form of Albe et al. when beta = 1 and m = 1. Note that in the current Tersoff implementation in LAMMPS, m must be specified as either 3 or 1. Tersoff used a slightly different but equivalent form for alloys, which we will refer to as Tersoff_2 potential (Tersoff_2).

LAMMPS parameter values for Tersoff_2 can be obtained as follows: \( \gamma = \omega_{ijk} \), \( \lambda_3 = 0 \) and the value of m has no effect. The parameters for species i and j can be calculated using the Tersoff_2 mixing rules:

\[
\begin{align*}
\lambda_{i,j}^1 &= \frac{1}{2}(\lambda_i^1 + \lambda_j^1) \\
\lambda_{i,j}^2 &= \frac{1}{2}(\lambda_i^2 + \lambda_j^2) \\
A_{i,j} &= (A_i A_j)^{1/2} \\
B_{i,j} &= \chi_{ij} (B_i B_j)^{1/2} \\
R_{i,j} &= (R_i R_j)^{1/2} \\
S_{i,j} &= (S_i S_j)^{1/2}
\end{align*}
\]

Tersoff_2 parameters R and S must be converted to the LAMMPS parameters R and D (R is different in both forms), using the following relations: \( R = (R' + S')/2 \) and \( D = (S' - R')/2 \), where the primes indicate the Tersoff_2 parameters.

In the potentials directory, the file SiCGe.tersoff provides the LAMMPS parameters for Tersoff’s various versions of Si, as well as his alloy parameters for Si, C, and Ge. This file can be used for pure Si, (three different versions), pure C, pure Ge, binary SiC, and binary SiGe. LAMMPS will generate an error if this file is used with any combination involving C and Ge, since there are no entries for the GeC interactions (Tersoff did not publish parameters for this cross-interaction.) Tersoff files are also provided for the SiC alloy (SiC.tersoff) and the GaN (GaN.tersoff) alloys.

Many thanks to Rutuparna Narulkar, David Farrell, and Xiaowang Zhou for helping clarify how Tersoff parameters for alloys have been defined in various papers. Also thanks to Ram Devanathan for providing the base ZBL implementation.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} doc page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

---

**Mixing, shift, table, tail correction, restart, rRESPA info:**

For atom type pairs $I,J$ and $I \neq J$, where types $I$ and $J$ correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

---

### 18.444.4 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The Tersoff/ZBL potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the Tersoff potential with any LAMMPS units, but you would need to create your own Tersoff potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

18.447.1 Syntax

```
pair_style style args

• style = thole or lj/cut/thole/long or lj/cut/thole/long/omp
• args = list of arguments for a particular style
```

- thole args = damp cutoff
  - damp = global damping parameter
  - cutoff = global cutoff (distance units)
- lj/cut/thole/long or lj/cut/thole/long/omp args = damp cutoff (cutoff2)
  - damp = global damping parameter
  - cutoff = global cutoff for LJ (and Thole if only 1 arg) (distance units)
  - cutoff2 = global cutoff for Thole (optional) (distance units)

18.447.2 Examples

```
pair_style hybrid/overlay ... thole 2.6 12.0
pair_coeff 1 1 thole 1.0
pair_coeff 1 2 thole 1.0 2.6 10.0
pair_coeff * 2 thole 1.0 2.6

pair_style lj/cut/thole/long 2.6 12.0
```

18.447.3 Description

The thole pair styles are meant to be used with force fields that include explicit polarization through Drude dipoles. This link describes how to use the thermalized Drude oscillator model in LAMMPS and polarizable models in LAMMPS are discussed on the Howto polarizable doc page.

The thole pair style should be used as a sub-style within in the pair_style hybrid/overlay command, in conjunction with a main pair style including Coulomb interactions, i.e. any pair style containing coul/cut or coul/long in its style name.

The lj/cut/thole/long pair style is equivalent to, but more convenient that the frequent combination hybrid/overlay lj/cut/coul/long cutoff thole damp cutoff2. It is not only a shorthand for this pair_style combination, but it also allows for mixing pair coefficients instead of listing them all. The lj/cut/thole/long pair style is also a bit faster because it avoids an overlay and can benefit from OMP acceleration. Moreover, it uses a more precise approximation of the direct Coulomb interaction at short range similar to coul/long/cs, which stabilizes the temperature of Drude particles.

The thole pair styles compute the Coulomb interaction damped at short distances by a function

\[ T_{ij}(r_{ij}) = 1 - \left( 1 + \frac{s_{ij}r_{ij}}{2} \right) \exp \left( -s_{ij}r_{ij} \right) \]
This function results from an adaptation to point charges (Noskov) of the dipole screening scheme originally proposed by Thole. The scaling coefficient $s_{ij}$ is determined by the polarizability of the atoms, $\alpha_i$, and by a Thole damping parameter $a$. This Thole damping parameter usually takes a value of 2.6, but in certain force fields the value can depend upon the atom types. The mixing rule for Thole damping parameters is the arithmetic average, and for polarizabilities the geometric average between the atom-specific values.

$$s_{ij} = \frac{a_{ij}}{(\alpha_{ij})^{1/3}} = \frac{(a_i + a_j)/2}{[(a_i a_j)^{1/2}]^{1/3}}$$

The damping function is only applied to the interactions between the point charges representing the induced dipoles on polarizable sites, that is, charges on Drude particles, $q_{D,i}$, and opposite charges, $-q_{D,i}$, located on the respective core particles (to which each Drude particle is bonded). Therefore, Thole screening is not applied to the full charge of the core particle $q_i$, but only to the $-q_{D,i}$ part of it.

The interactions between core charges are subject to the weighting factors set by the special_bonds command. The interactions between Drude particles and core charges or non-polarizable atoms are also subject to these weighting factors. The Drude particles inherit the 1-2, 1-3 and 1-4 neighbor relations from their respective cores.

For pair_style thole, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the example above.

- $\alpha$ (distance units$^3$)
- $\text{damp}$
- cutoff (distance units)

The last two coefficients are optional. If not specified the global Thole damping parameter or global cutoff specified in the pair_style command are used. In order to specify a cutoff (third argument) a damp parameter (second argument) must also be specified.

For pair style lj/cut/thole/long, the following coefficients must be defined for each pair of atoms types via the pair_coeff command.

- $\epsilon$ (energy units)
- $\sigma$ (length units)
- $\alpha$ (distance units$^3$)
- $\text{damp}$
- LJ cutoff (distance units)

The last two coefficients are optional and default to the global values from the pair_style command line.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing:
The thole pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.
The \textit{lj/cut/thole/long} pair style does support mixing. Mixed coefficients are defined using

\[ \alpha_{ij} = \sqrt{\alpha_i \alpha_j} \]

\[ a_{ij} = \frac{1}{2} (a_i + a_j) \]

### 18.447.4 Restrictions

These pair styles are part of the USER-DRUDE package. They are only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

This pair style should currently not be used with the \textit{charmm dihedral style} if the latter has non-zero 1-4 weighting factors. This is because the \textit{thole} pair style does not know which pairs are 1-4 partners of which dihedrals.

The \textit{lj/cut/thole/long} pair style should be used with a \textit{Kspace solver} like PPPM or Ewald, which is only enabled if LAMMPS was built with the kspace package.

### 18.448 pair_style tri/lj command

#### 18.448.1 Syntax

\texttt{pair\_style tri/lj cutoff}

cutoff = global cutoff for interactions (distance units)

#### 18.448.2 Examples

\begin{verbatim}
pair_style tri/lj 3.0
pair_coeff * * 1.0 1.0
pair_coeff 1 1 1.0 1.5 2.5
\end{verbatim}
18.448.3 Description

Style tri/lj treats particles which are triangles as a set of small spherical particles that tile the triangle surface as explained below. Interactions between two triangles, each with N1 and N2 spherical particles, are calculated as the pairwise sum of N1*N2 Lennard-Jones interactions. Interactions between a triangle with N spherical particles and a point particle are treated as the pairwise sum of N Lennard-Jones interactions. See the pair_style lj/cut doc page for the definition of Lennard-Jones interactions.

The cutoff distance for an interaction between 2 triangles, or between a triangle and a point particle, is calculated from the position of the triangle (its centroid), not between pairs of individual spheres comprising the triangle. Thus an interaction is either calculated in its entirety or not at all.

The set of non-overlapping spherical particles that represent a triangle, for purposes of this pair style, are generated in the following manner. Assume the triangle is of type I, and sigma_II has been specified. We want a set of spheres with centers in the plane of the triangle, none of them larger in diameter than sigma_II, which completely cover the triangle’s area, but with minimal overlap and a minimal total number of spheres. This is done in a recursive manner. Place a sphere at the centroid of the original triangle. Calculate what diameter it must have to just cover all 3 corner points of the triangle. If that diameter is equal to or smaller than sigma_II, then include a sphere of the calculated diameter in the set of covering spheres. If the diameter is larger than sigma_II, then split the triangle into 2 triangles by bisecting its longest side. Repeat the process on each sub-triangle, recursing as far as needed to generate a set of covering spheres. When finished, the original criteria are met, and the set of covering spheres should be near minimal in number and overlap, at least for input triangles with a reasonable aspect-ratio.

The LJ interaction between 2 spheres on different triangles of types I,J is computed with an arithmetic mixing of the sigma values of the 2 spheres and using the specified epsilon value for I,J atom types. Note that because the sigma values for triangles spheres is computed using only sigma_II values, specific to the triangles’s type, this means that any specified sigma_IJ values (for I != J) are effectively ignored.

For style tri/lj, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- epsilon (energy units)
- sigma (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.
18.448.4 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Defining particles to be triangles so they participate in tri/tri or tri/particle interactions requires the use the atom_style tri command.

18.448.5 Related commands

pair_coeff, pair_style line/lj

Default: none

18.449 pair_style ufm command

18.450 pair_style ufm/gpu command

18.451 pair_style ufm/omp command

18.452 pair_style ufm/opt command

18.452.1 Syntax

pair_style ufm cutoff

- cutoff = global cutoff for ufm interactions (distance units)

18.452.2 Examples

```plaintext
pair_style ufm 4.0
pair_coeff 1 1 100.0 1.0 2.5
pair_coeff * * 10.0 1.0

pair_style ufm 4.0
pair_coeff * * 10.0 1.0
variable prefactor equal ramp(10,100)
fix 1 all adapt 1 pair ufm epsilon * * v_prefactor
```
18.452.3 Description

Style ufm computes pairwise interactions using the Uhlenbeck-Ford model (UFM) potential (Paula Leite2016) which is given by

\[ E = -\varepsilon \ln \left[ 1 - \exp \left( -r^2 / \sigma^2 \right) \right] \quad r < r_c \]
\[ \varepsilon = p k_B T \]

where \( r_c \) is the cutoff, \( \sigma \) is a distance-scale and \( \varepsilon \) is an energy-scale, i.e., a product of Boltzmann constant \( k_B \), temperature \( T \) and the Uhlenbeck-Ford \( p \)-parameter which is responsible to control the softness of the interactions (Paula Leite2017). This model is useful as a reference system for fluid-phase free-energy calculations (Paula Leite2016).

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- \( \varepsilon \) (energy units)
- \( \sigma \) (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global ufm cutoff is used.

The fix adapt command can be used to vary epsilon and sigma for this pair style over the course of a simulation, in which case pair_coeff settings for epsilon and sigma must still be specified, but will be overridden. For example these commands will vary the prefactor epsilon for all pairwise interactions from 10.0 at the beginning to 100.0 at the end of a run:

```plaintext
variable prefactor equal ramp(10,100)
fix 1 all adapt 1 pair ufm epsilon * * v_prefactor
```

Note: The thermodynamic integration procedure can be performed with this potential using fix adapt. This command will rescale the force on each atom by varying a scale variable, which always starts with value 1.0. The syntax is the same described above, however, changing epsilon to scale. A detailed explanation of how to use this command and perform nonequilibrium thermodynamic integration in LAMMPS is given in the paper by (Freitas).

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I !\( = \) J, the A coefficient and cutoff distance for this pair style can be mixed. A is always mixed via a geometric rule. The cutoff is mixed according to the pair_modify mix value. The default mix value is geometric. See the “pair_modify” command for details.
This pair style supports the `pair_modify` shift option for the energy of the pair interaction. The `pair_modify` table and tail are not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

pair_style vashishta/table 100000 0.2
pair_coeff * * SiC.vashishta Si C
```

18.458.3 Description

The `vashishta` and `vashishta/table` styles compute the combined 2-body and 3-body family of potentials developed in the group of Priya Vashishta and collaborators. By combining repulsive, screened Coulombic, screened charge-dipole, and dispersion interactions with a bond-angle energy based on the Stillinger-Weber potential, this potential has been used to describe a variety of inorganic compounds, including SiO2 [Vashishta1990], SiC [Vashishta2007], and InP [Branicio2009].

The potential for the energy \( U \) of a system of atoms is

\[
U = \sum_{i}^{N} \sum_{j>i}^{N} U_{ij}^{(2)}(r_{ij}) + \sum_{i}^{N} \sum_{j\neq i}^{N} \sum_{k\neq i}^{N} U_{ijk}^{(3)}(r_{ij}, r_{ik}, \theta_{ijk})
\]

where we follow the notation used in [Branicio2009]. \( U^{2} \) is a two-body term and \( U^{3} \) is a three-body term. The summation over two-body terms is over all neighbors \( J \) within a cutoff distance \( = r_{c} \). The twobody terms are shifted and tilted by a linear function so that the energy and force are both zero at \( r_{c} \). The summation over three-body terms is over all neighbors \( i \) and \( k \) within a cut-off distance \( = r_{0} \), where the exponential screening function becomes zero.

The `vashishta` style computes these formulas analytically. The `vashishta/table` style tabulates the analytic values for \( N_{table} \) points from cutinner to the cutoff of the potential. The points are equally spaced in \( R^{2} \) space from cutinner\(^2\) to cutoff\(^2\). For the two-body term in the above equation, a linear interpolation for each pairwise distance between adjacent points in the table. In practice the tabulated version can run 3-5x faster than the analytic version with moderate to little loss of accuracy for \( N_{table} \) values between 10000 and 1000000. It is not recommended to use less than 5000 tabulation points.

Only a single pair_coeff command is used with either style which specifies a Vashishta potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:

- filename
- \( N \) element names = mapping of Vashishta elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.
As an example, imagine a file SiC.vashishta has parameters for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

\begin{verbatim}
pair_coeff * * SiC.vashishta Si Si Si C
\end{verbatim}

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the file. The final C argument maps LAMMPS atom type 4 to the C element in the file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a vashishta potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Vashishta files in the potentials directory of the LAMMPS distribution have a "vashishta" suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formulae above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- \( H \) (energy units)
- \( \eta \)
- \( Z_i \) (electron charge units)
- \( Z_j \) (electron charge units)
- \( \lambda_1 \) (distance units)
- \( D \) (energy units)
- \( \lambda_4 \) (distance units)
- \( W \) (energy units)
- \( r_c \) (distance units)
- \( B \) (energy units)
- \( \gamma \)
- \( r_0 \) (distance units)
- \( C \)
- \( \cos \theta_0 \)

The non-annotated parameters are unitless. The Vashishta potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries. For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSI, CCC), that specify parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

Depending on the particular version of the Vashishta potential, the values of these parameters may be keyed to the identities of zero, one, two, or three elements. In order to make the input file format unambiguous, general, and simple to code, LAMMPS uses a slightly confusing method for specifying parameters. All parameters are divided into two classes: two-body and three-body. Two-body and three-body parameters are handled differently, as described below.

The two-body parameters are \( H, \eta, \lambda_1, D, \lambda_4, W, r_c, \gamma, \) and \( r_0 \). They appear in the above formulae with two subscripts. The parameters \( Z_i \) and \( Z_j \) are also classified as two-body parameters, even though they only have 1 subscript. The three-body parameters are \( B, C, \cos \theta_0 \). They appear in the above formulae with three subscripts. Two-body and three-body parameters are handled differently, as described below.
The first element in each entry is the center atom in a three-body interaction, while the second and third elements are two neighbor atoms. Three-body parameters for a central atom I and two neighbors J and K are taken from the IJK entry. Note that even though three-body parameters do not depend on the order of J and K, LAMMPS stores three-body parameters for both IJK and IKJ. The user must ensure that these values are equal. Two-body parameters for an atom I interacting with atom J are taken from the IJ entry, where the second and third elements are the same. Thus the two-body parameters for Si interacting with C come from the SiCC entry. Note that even though two-body parameters (except possibly gamma and $r_0$ in $U_3$) do not depend on the order of the two elements, LAMMPS will get the Si-C value from the SiCC entry and the C-Si value from the CSI Si entry. The user must ensure that these values are equal. Two-body parameters appearing in entries where the second and third elements are different are stored but never used. It is good practice to enter zero for these values. Note that the three-body function $U_3$ above contains the two-body parameters $\gamma$ and $r_0$. So $U_3$ for a central C atom bonded to an Si atom and a second C atom will take three-body parameters from the CSCI entry, but two-body parameters from the CCC and CSI Si entries.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs IJ and I ≠ J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 18.458.4 Restrictions

These pair style are part of the MANYBODY package. They is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair styles requires the `newton` setting to be “on” for pair interactions.

The Vashishta potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the Vashishta potential with any LAMMPS units, but you would need to create your own potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

pair_style yukawa kappa cutoff

- kappa = screening length (inverse distance units)
- cutoff = global cutoff for Yukawa interactions (distance units)

18.462.2 Examples

pair_style yukawa 2.0 2.5
pair_coeff 1 1 100.0 2.3
pair_coeff * * 100.0

18.462.3 Description

Style yukawa computes pairwise interactions with the formula

\[ E = \frac{A e^{-\kappa r}}{r} \quad r < r_c \]

\( r_c \) is the cutoff.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- A (energy*distance units)
- cutoff (distance units)
The last coefficient is optional. If not specified, the global yukawa cutoff is used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `--suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs I,J and I != J, the A coefficient and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the `pair_modify` shift option for the energy of the pair interaction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the run_style respa command. It does not support the `inner`, `middle`, `outer` keywords.

18.462.4 Restrictions

none

18.462.5 Related commands

`pair_coeff`

Default: none
18.463 pair_style yukawa/colloid command

18.464 pair_style yukawa/colloid/gpu command

18.465 pair_style yukawa/colloid/omp command

18.465.1 Syntax

```
pair_style yukawa/colloid kappa cutoff
```

- kappa = screening length (inverse distance units)
- cutoff = global cutoff for colloidal Yukawa interactions (distance units)

18.465.2 Examples

```
pair_style yukawa/colloid 2.0 2.5
pair_coeff 1 1 100.0 2.3
pair_coeff * * 100.0 2.3
```

18.465.3 Description

Style `yukawa/colloid` computes pairwise interactions with the formula

\[ E = \frac{A}{\kappa} e^{-\kappa(r_i + r_j - r)} \quad r < r_c \]

where \( r_i \) and \( r_j \) are the radii of the two particles and \( r_c \) is the cutoff.

In contrast to `pair_style yukawa`, this functional form arises from the Coulombic interaction between two colloid particles, screened due to the presence of an electrolyte, see the book by Safran for a derivation in the context of DLVO theory. `Pair_style yukawa` is a screened Coulombic potential between two point-charges and uses no such approximation.

This potential applies to nearby particle pairs for which the Derjagin approximation holds, meaning \( h << r_i + r_j \), where \( h \) is the surface-to-surface separation of the two particles.

When used in combination with `pair_style colloid`, the two terms become the so-called DLVO potential, which combines electrostatic repulsion and van der Waals attraction.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- A (energy/distance units)
- cutoff (distance units)

The prefactor \( A \) is determined from the relationship between surface charge and surface potential due to the presence of electrolyte. Note that the \( A \) for this potential style has different units than the \( A \) used in `pair_style yukawa`. For low surface potentials, i.e. less than about 25 mV, \( A \) can be written as:

\[ A = 2\pi R \varepsilon_0 \kappa \psi^2 \]

where
• $R$ = colloid radius (distance units)
• $\varepsilon_0$ = permittivity of free space (charge$^2$/energy/distance units)
• $\varepsilon$ = relative permittivity of fluid medium (dimensionless)
• $\kappa$ = inverse screening length (1/distance units)
• $\psi$ = surface potential (energy/charge units)

The last coefficient is optional. If not specified, the global yukawa/colloid cutoff is used.

Styles with a `gpu`, `intel`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Mixing, shift, table, tail correction, restart, rRESPA info:

For atom type pairs $I,J$ and $I \neq J$, the $A$ coefficient and cutoff distance for this pair style can be mixed. $A$ is an energy value mixed like a LJ epsilon. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the `pair_modify` shift option for the energy of the pair interaction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

18.465.4 Restrictions

This style is part of the COLLOID package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires that atoms be finite-size spheres with a diameter, as defined by the `atom_style sphere` command.

Per-particle polydispersity is not yet supported by this pair style; per-type polydispersity is allowed. This means all particles of the same type must have the same diameter. Each type can have a different diameter.
18.465.5 Related commands

pair_coeff

Default: none

18.466 pair_style zbl command

18.467 pair_style zbl/gpu command

18.468 pair_style zbl/kk command

18.469 pair_style zbl/omp command

18.469.1 Syntax

```
pair_style zbl inner outer
```

- inner = distance where switching function begins
- outer = global cutoff for ZBL interaction

18.469.2 Examples

```
pair_style  zbl  3.0  4.0
pair_coeff  *  *  73.0  73.0
pair_coeff  1  1  14.0  14.0
```

18.469.3 Description

Style zbl computes the Ziegler-Biersack-Littmark (ZBL) screened nuclear repulsion for describing high-energy collisions between atoms. (Ziegler). It includes an additional switching function that ramps the energy, force, and curvature smoothly to zero between an inner and outer cutoff. The potential energy due to a pair of atoms at a distance \( r_{ij} \) is given by:

\[
E^{ZBL}_{ij} = \frac{1}{4\pi\epsilon_0} \frac{Z_i Z_j e^2}{r_{ij}} \phi\left(\frac{r_{ij}}{a}\right) + S\left(r_{ij}\right)
\]

\[
a = \frac{0.46850}{Z_i^{0.23} + Z_j^{0.23}}
\]

\[
\phi(x) = 0.18175e^{-3.19980x} + 0.50986e^{-0.94229x} + 0.28022e^{-0.40290x} + 0.02817e^{-0.20162x}
\]

where \( e \) is the electron charge, \( \epsilon_0 \) is the electrical permittivity of vacuum, and \( Z_i \) and \( Z_j \) are the nuclear charges of the two atoms. The switching function \( S(r) \) is identical to that used by pair_style lj/gromacs. Here, the inner and outer cutoff are the same for all pairs of atom types.
The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the LAMMPS data file.

- $Z_i$ (atomic number for first atom type, e.g. 13.0 for aluminum)
- $Z_j$ (ditto for second atom type)

The values of $Z_i$ and $Z_j$ are normally equal to the atomic numbers of the two atom types. Thus, the user may optionally specify only the coefficients for each $i == i$ pair, and rely on the obvious mixing rule for cross interactions (see below). Note that when $i == i$ it is required that $Z_i == Z_j$. When used with `hybrid/overlay` and pairs are assigned to more than one sub-style, the mixing rule is not used and each pair of types interacting with the ZBL sub-style must be included in a `pair_coeff` command.

**Note:** The numerical values of the exponential decay constants in the screening function depend on the unit of distance. In the above equation they are given for units of angstroms. LAMMPS will automatically convert these values to the distance unit of the specified LAMMPS `units` setting. The values of $Z$ should always be given as multiples of a proton’s charge, e.g. 29.0 for copper.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

For atom type pairs $i,j$ and $i != i$, the $Z_i$ and $Z_j$ coefficients can be mixed by taking $Z_i$ and $Z_j$ from the values specified for $i == i$ and $j == j$ cases. When used with `hybrid/overlay` and pairs are assigned to more than one sub-style, the mixing rule is not used and each pair of types interacting with the ZBL sub-style must be included in a `pair_coeff` command. The `pair_modify` mix option has no effect on the mixing behavior.

The ZBL pair style does not support the `pair_modify` shift option, since the ZBL interaction is already smoothed to 0.0 at the cutoff.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

This pair style does not write information to binary restart files, so `pair_style` and `pair_coeff` commands must be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.
18.469.4 Restrictions

none

18.469.5 Related commands

pair_coeff

Default: none

18.470 pair_style zero command

18.470.1 Syntax

```
pair_style zero cutoff [nocoeff]
```

- zero = style name of this pair style
- cutoff = global cutoff (distance units)
- nocoeff = ignore all pair_coeff parameters (optional)

18.470.2 Examples

```
pair_style zero 10.0
pair_style zero 5.0 nocoeff
pair_coeff * *
pair_coeff 1 2*4 3.0
```

18.470.3 Description

Define a global or per-type cutoff length for the purpose of building a neighbor list and acquiring ghost atoms, but do not compute any pairwise forces or energies.

This can be useful for fixes or computes which require a neighbor list to enumerate pairs of atoms within some cutoff distance, but when pairwise forces are not otherwise needed. Examples are the fix bond/create, compute rdf, compute voronoi/atom commands.

Note that the comm_modify cutoff command can be used to insure communication of ghost atoms even when a pair style is not defined, but it will not trigger neighbor list generation.

The optional nocoeff flag allows to read data files with a PairCoeff section for any pair style. Similarly, any pair_coeff commands will only be checked for the atom type numbers and the rest ignored. In this case, only the global cutoff will be used.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:
- cutoff (distance units)

This coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used. If the pair_style has been specified with the optional nocoeff flag, then a cutoff pair coefficient is ignored.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

The cutoff distance for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the inner, middle, and outer keywords of the run_style respa command.

19.7.2 Examples

```
bond_style fene
bond_coeff 1 30.0 1.5 1.0 1.0
```

19.7.3 Description

The `fene` bond style uses the potential

\[
E = -0.5K R_0^2 \ln \left( 1 - \left( \frac{r}{R_0} \right)^2 \right) + 4 \epsilon \left[ \frac{\sigma^{12}}{r} - \frac{\sigma^6}{r} \right] + \epsilon
\]

to define a finite extensible nonlinear elastic (FENE) potential (Kremer), used for bead-spring polymer models. The first term is attractive, the second Lennard-Jones term is repulsive. The first term extends to \( R_0 \), the maximum extent of the bond. The second term is cutoff at \( 2^{\frac{1}{6}} \sigma \), the minimum of the LJ potential.

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy/distance\(^2\))
- \( R_0 \) (distance)
- \( \epsilon \) (energy)
- \( \sigma \) (distance)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

19.7.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

You typically should specify `special_bonds fene` or `special_bonds lj/coul 0 1 1` to use this bond style. LAMMPS will issue a warning if that’s not the case.

19.7. bond_style fene/omp command
19.7.5 Related commands

*bond_coeff*, *delete_bonds*

**Default:** none

19.8 bond_style fene/expand command

19.9 bond_style fene/expand/omp command

19.9.1 Syntax

```
bond_style fene/expand
```

19.9.2 Examples

```
bond_style fene/expand
bond_coeff 1 30.0 1.5 1.0 1.0 0.5
```

19.9.3 Description

The *fene/expand* bond style uses the potential

\[ E = -0.5KR_0^2 \ln \left[ 1 - \left( \frac{(r - \Delta)}{R_0} \right)^2 \right] + 4\epsilon \left[ \frac{\sigma}{(r - \Delta)} \right]^{12} - \left[ \frac{\sigma}{(r - \Delta)} \right]^6 + \epsilon \]

to define a finite extensible nonlinear elastic (FENE) potential (Kremer), used for bead-spring polymer models. The first term is attractive, the second Lennard-Jones term is repulsive.

The *fene/expand* bond style is similar to *fene* except that an extra shift factor of \( \Delta \) (positive or negative) is added to \( r \) to effectively change the bead size of the bonded atoms. The first term now extends to \( R_0 + \Delta \) and the second term is cutoff at \( 2^6\sigma + \Delta \).

The following coefficients must be defined for each bond type via the *bond_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( K \) (energy/distance^2)
- \( R_0 \) (distance)
- \( \epsilon \) (energy)
- \( \sigma \) (distance)
- \( \Delta \) (distance)
Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. 19.19.5 Related commands
bond_coeff, delete_bonds, bond_harmonic, bond_style harmonic/shift

Default: none

19.20 bond_style hybrid command

19.20.1 Syntax

bond_style hybrid style1 style2 ...

• style1,style2 = list of one or more bond styles

19.20.2 Examples

19.20.3 Description

The hybrid style enables the use of multiple bond styles in one simulation. A bond style is assigned to each bond type. For example, bonds in a polymer flow (of bond type 1) could be computed with a fene potential and bonds in the wall boundary (of bond type 2) could be computed with a harmonic potential. The assignment of bond type to style is made via the bond_coeff command or in the data file.

In the bond_coeff commands, the name of a bond style must be added after the bond type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 bond_coeff commands set bonds of bond type 1 to be computed with a harmonic potential with coefficients 80.0, 1.2 for \( K, r_0 \). All other bond types (2-N) are computed with a fene potential with coefficients 30.0, 1.5, 1.0, 1.0 for \( K, R_0, \epsilon, \sigma \).

If bond coefficients are specified in the data file read via the read_data command, then the same rule applies. E.g. “harmonic” or “fene” must be added after the bond type, for each line in the “Bond Coeffs” section, e.g.
Bond Coeffs

1 harmonic 80.0 1.2
2 fene 30.0 1.5 1.0 1.0
...

A bond style of *none* with no additional coefficients can be used in place of a bond style, either in a input script bond_coeff command or in the data file, if you desire to turn off interactions for specific bond types.

### 19.20.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* documentation page for more info.

Unlike other bond styles, the hybrid bond style does not store bond coefficient info for individual sub-styles in a binary restart files. Thus when restarting a simulation from a restart file, you need to re-specify bond_coeff commands.

### 19.20.5 Related commands

* bond_coeff, delete_bonds

### 19.21 bond_style mm3 command

#### 19.21.1 Syntax

```
bond_style mm3
```

#### 19.21.2 Examples

```
bond_style mm3
bond_coeff 1 100.0 107.0
```

#### 19.21.3 Description

The *mm3* bond style uses the potential that is anharmonic in the bond as defined in *(Allinger)*

\[
E = K (r - r_0)^2 \left[ 1 - 2.55 (r - r_0) + \left( \frac{7}{12} \right) 2.55^2 (r - r_0)^2 \right]
\]

where \( r_0 \) is the equilibrium value of the bond, and \( K \) is a prefactor. The anharmonic prefactors have units angstrom\(^n\): -2.55 angstrom\(^{-1}\) and \( (7/12) 2.55^2 \) angstrom\(^{-2}\). The code takes care of the necessary unit conversion for these factors internally. Note that the MM3 papers contains an error in Eq (1): \( (7/12) 2.55 \) should be replaced with \( (7/12) 2.55^2 \)

The following coefficients must be defined for each bond type via the bond_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:
19.21.4 Restrictions

This bond style can only be used if LAMMPS was built with the USER_YAFF package. See the Build package doc page for more info.

19.27 bond\_style oxdna/fene command

19.28 bond\_style oxdna2/fene command

19.29 bond\_style oxrna2/fene command

19.29.1 Syntax

\begin{verbatim}
bond_style oxdna/fene
bond_style oxdna2/fene
bond_style oxrna2/fene
\end{verbatim}

19.29.2 Examples

\begin{verbatim}
bond_style oxdna/fene
bond_coeff *= 2.0 0.25 0.7525

bond_style oxdna2/fene
bond_coeff *= 2.0 0.25 0.7564

bond_style oxrna2/fene
bond_coeff *= 2.0 0.25 0.76107
\end{verbatim}
19.29.3 Description

The oxdna/fene, oxdna2/fene and oxrna2/fene bond styles use the potential

\[ E = -\frac{\epsilon}{2} \ln \left[ 1 - \left( \frac{r - r_0}{\Delta} \right)^2 \right] \]

to define a modified finite extensible nonlinear elastic (FENE) potential (Ouldridge) to model the connectivity of the phosphate backbone in the oxDNA/oxRNA force field for coarse-grained modelling of DNA/RNA.

The following coefficients must be defined for the bond type via the bond_coeff command as given in the above example, or in the data file or restart files read by the read_data or read_restart commands:

- \( \epsilon \) (energy)
- \( \Delta \) (distance)
- \( r_0 \) (distance)

**Note:** The oxDNA bond style has to be used together with the corresponding oxDNA pair styles for excluded volume interaction oxdna/excv, stacking oxdna/stk, cross-stacking oxdna/xstk and coaxial stacking interaction oxdna/coaxstk as well as hydrogen-bonding interaction oxdna/hbond (see also documentation of pair_style oxdna/excv). For the oxDNA2 (Snodin) bond style the analogous pair styles oxdna2/excv, oxdna2/stk, oxdna2/xstk, oxdna2/coaxstk, oxdna2/hbond and an additional Debye-Hueckel pair style oxdna2/dh have to be defined. The same applies to the oxRNA2 (Sulc1) styles. The coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model.

Example input and data files for DNA and RNA duplexes can be found in examples/USER/cgdna/examples/oxDNA/, /oxDNA2/ and /oxRNA2/. A simple python setup tool which creates single straight or helical DNA strands, DNA/RNA duplexes or arrays of DNA/RNA duplexes can be found in examples/USER/cgdna/util/.

Please cite (Henrich) in any publication that uses this implementation. The article contains general information on the model, its implementation and performance as well as the structure of the data and input file. The preprint version of the article can be found here. Please cite also the relevant oxDNA/oxRNA publications. These are (Ouldridge) and (Ouldridge-DPhil) for oxDNA, (Snodin) for oxDNA2, (Sulc1) for oxRNA2 and for sequence-specific hydrogen-bonding and stacking interactions (Sulc2).

19.29.4 Restrictions

This bond style can only be used if LAMMPS was built with the USER-CG DNA package and the MOLECULE and ASPHERE package. See the Build package doc page for more info.

19.29.5 Related commands

pair_style oxdna/excv, pair_style oxdna2/excv, pair_style oxrna2/excv, bond_coeff, fix nve/dotc/langevin

Default: none

19.30 bond_style quartic command

19.31 bond_style quartic/omp command

19.31.1 Syntax

```
bond_style quartic
```

19.31.2 Examples

```
bond_style quartic
bond_coeff 2 1200 -0.55 0.25 1.3 34.6878
```

19.31.3 Description

The *quartic* bond style uses the potential

\[
E = K(r - R_c)^2(r - R_c - B_1)(r - R_c - B_2) + U_0 + 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] + \epsilon
\]

to define a bond that can be broken as the simulation proceeds (e.g. due to a polymer being stretched). The \(\sigma\) and \(\epsilon\) used in the LJ portion of the formula are both set equal to 1.0 by LAMMPS.

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \(K\) (energy/distance^4)
- \(B_1\) (distance)
- \(B_2\) (distance)
- \(R_c\) (distance)
- \(U_0\) (energy)

This potential was constructed to mimic the FENE bond potential for coarse-grained polymer chains. When monomers with \(\sigma = \epsilon = 1.0\) are used, the following choice of parameters gives a quartic potential that looks nearly like the FENE.
potential:

\[
\begin{align*}
K &= 1200 \\
B_1 &= -0.55 \\
B_2 &= 0.25 \\
R_c &= 1.3 \\
U_0 &= 34.6878
\end{align*}
\]

Different parameters can be specified using the `bond_coeff` command, but you will need to choose them carefully so they form a suitable bond potential.

`R_c` is the cutoff length at which the bond potential goes smoothly to a local maximum. If a bond length ever becomes \(> R_c\), LAMMPS “breaks” the bond, which means two things. First, the bond potential is turned off by setting its type to 0, and is no longer computed. Second, a pairwise interaction between the two atoms is turned on, since they are no longer bonded.

LAMMPS does the second task via a computational sleight-of-hand. It subtracts the pairwise interaction as part of the bond computation. When the bond breaks, the subtraction stops. For this to work, the pairwise interaction must always be computed by the `pair_style` command, whether the bond is broken or not. This means that `special_bonds` must be set to 1,1,1, as indicated as a restriction below.

Note that when bonds are dumped to a file via the `dump local` command, bonds with type 0 are not included. The `delete_bonds` command can also be used to query the status of broken bonds or permanently delete them, e.g.:

```plaintext
delete_bonds  all  stats
delete_bonds  all  bond  0  remove
```

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `--suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 19.31.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

The `quartic` style requires that `special_bonds` parameters be set to 1,1,1. Three- and four-body interactions (angle, dihedral, etc) cannot be used with `quartic` bonds.
19.31.5 Related commands

`bond_coeff, delete_bonds`

**Default:** none

19.32 bond_style table command

19.33 bond_style table/omp command

19.33.1 Syntax

```plaintext
bond_style table style N
```

- `style = linear` or `spline` = method of interpolation
- `N = use N values in table`

19.33.2 Examples

```plaintext
bond_style table linear 1000
bond_coeff 1 file.table ENTRY1
```

19.33.3 Description

Style `table` creates interpolation tables of length `N` from bond potential and force values listed in a file(s) as a function of bond length. The files are read by the `bond_coeff` command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and force values at each of `N` distances. During a simulation, these tables are used to interpolate energy and force values as needed. The interpolation is done in one of 2 styles: `linear` or `spline`.

For the `linear` style, the bond length is used to find 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the `spline` style, a cubic spline coefficients are computed and stored at each of the `N` values in the table. The bond length is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above.

- `filename`
- `keyword`

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments):
A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the bond_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the bond_style table command. Let Ntable = N in the bond_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and force values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and force for individual bond lengths. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile.

The “FP” parameter is optional. If used, it is followed by two values fplo and fphi, which are the derivatives of the force at the innermost and outermost bond lengths. These values are needed by the spline construction routines. If not specified by the “FP” parameter, they are estimated (less accurately) by the first two and last two force values in the table.

The “EQ” parameter is also optional. If used, it is followed by the equilibrium bond length, which is used, for example, by the fix shake command. If not used, the equilibrium bond length is to the distance in the table with the lowest potential energy.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the bond length r (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The bond lengths must range from a LO value to a HI value, and increase from one line to the next. If the actual bond length is ever smaller than the LO value or larger than the HI value, then the calculation is aborted with an error, so it is advisable to cover the whole range of possible bond lengths.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

Restart info:
This bond style writes the settings for the “bond_style table” command to binary restart files, so a bond_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, bond_coeff commands do need to be specified in the restart input script.

19.33.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

19.33.5 Related commands

bond_coeff, delete_bonds

Default: none

19.34 bond_style zero command

19.34.1 Syntax

```
bond_style zero [nocoeff]
```

19.34.2 Examples

```
bond_style zero
bond_style zero nocoeff
bond_coeff *
bond_coeff * 2.14
```

19.34.3 Description

Using an bond style of zero means bond forces and energies are not computed, but the geometry of bond pairs is still accessible to other commands.

As an example, the compute bond/local command can be used to compute distances for the list of pairs of bond atoms listed in the data file read by the read_data command. If no bond style is defined, this command cannot be used.

The optional nocoeff flag allows to read data files with a BondCoeff section for any bond style. Similarly, any bond_coeff commands will only be checked for the bond type number and the rest ignored.

Note that the bond_coeff command must be used for all bond types. If specified, there can be only one value, which is going to be used to assign an equilibrium distance, e.g. for use with fix shake.

ANGLE STYLES

20.1 angle_style charmm command

20.2 angle_style charmm/intel command

20.3 angle_style charmm/kk command

20.4 angle_style charmm/omp command

20.4.1 Syntax

```
angle_style charmm
```

20.4.2 Examples

```
angle_style charmm
angle_coeff 1 300.0 107.0 50.0 3.0
```

20.4.3 Description

The charmm angle style uses the potential

\[ E = K(\theta - \theta_0)^2 + K_{ub}(r - r_{ub})^2 \]

with an additional Urey_Bradley term based on the distance \( r \) between the first and third atoms in the angle. \( K, \theta_0, K_{ub}, \) and \( R_{ub} \) are coefficients defined for each angle type.

See (MacKerell) for a description of the CHARMM force field.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy/radian^2)
- \( \theta_0 \) (degrees)
- \( K_{ub} \) (energy/distance^2)
- \( r_{ub} \) (distance)
\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence the units of \( K \) are in energy/radian^2.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix} command-line switch when you invoke LAMMPS, or you can use the \textit{suffic} command in your input script.

See \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

### 20.4.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the \textit{Build package} doc page for more info.

### 20.4.5 Related commands

\textit{angle_coeff}

\textbf{Default: none}

### 20.5 \texttt{angle\_style class2} command

### 20.6 \texttt{angle\_style class2/kk} command

### 20.7 \texttt{angle\_style class2/omp} command

### 20.8 \texttt{angle\_style class2/p6} command

### 20.8.1 Syntax

\begin{verbatim}
angle_style class2
\end{verbatim}
20.8.2 Examples

```
angle_style class2
angle_coeff * 75.0
angle_coeff 1 bb 10.5872 1.0119 1.5228
angle_coeff * ba 3.6551 24.895 1.0119 1.5228
```

20.8.3 Description

The `class2` angle style uses the potential

\[
E = E_a + E_{bb} + E_{ba}
\]

\[
E_a = K_2(\theta - \theta_0)^2 + K_3(\theta - \theta_0)^3 + K_4(\theta - \theta_0)^4
\]

\[
E_{bb} = M(r_{ij} - r_1)(r_{jk} - r_2)
\]

\[
E_{ba} = N_1(r_{ij} - r_1)(\theta - \theta_0) + N_2(r_{jk} - r_2)(\theta - \theta_0)
\]

where \(E_a\) is the angle term, \(E_{bb}\) is a bond-bond term, and \(E_{ba}\) is a bond-angle term. \(\theta_0\) is the equilibrium angle and \(r_1\) and \(r_2\) are the equilibrium bond lengths.

See *Sun* for a description of the COMPASS class2 force field.

Coefficients for the \(E_a\), \(E_{bb}\), and \(E_{ba}\) formulas must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands.

These are the 4 coefficients for the \(E_a\) formula:

- \(\theta_0\) (degrees)
- \(K_2\) (energy/radian^2)
- \(K_3\) (energy/radian^3)
- \(K_4\) (energy/radian^4)

\(\theta_0\) is specified in degrees, but LAMMPS converts it to radians internally; hence the units of the various \(K\) are in per-radian.

For the \(E_{bb}\) formula, each line in a `angle_coeff` command in the input script lists 4 coefficients, the first of which is “bb” to indicate they are BondBond coefficients. In a data file, these coefficients should be listed under a “BondBond Coeffs” heading and you must leave out the “bb”, i.e. only list 3 coefficients after the angle type.

- bb
- \(M\) (energy/distance^2)
- \(r_1\) (distance)
- \(r_2\) (distance)

For the \(E_{ba}\) formula, each line in a `angle_coeff` command in the input script lists 5 coefficients, the first of which is “ba” to indicate they are BondAngle coefficients. In a data file, these coefficients should be listed under a “BondAngle Coeffs” heading and you must leave out the “ba”, i.e. only list 4 coefficients after the angle type.

- ba
- \(N_1\) (energy/distance^2)
- \(N_2\) (energy/distance^2)
- \(r_1\) (distance)
- \(r_2\) (distance)
The $\theta_0$ value in the $E_{ba}$ formula is not specified, since it is the same value from the $E_a$ formula.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

The `class2/p6` angle style uses the `class2` potential expanded to sixth order:

$$E_a = K_2 (\theta - \theta_0)^2 + K_3 (\theta - \theta_0)^3 + K_4 (\theta - \theta_0)^4 + K_5 (\theta - \theta_0)^5 + K_6 (\theta - \theta_0)^6$$

In this expanded term 6 coefficients for the $E_a$ formula need to be set:

- $\theta_0$ (degrees)
- $K_2$ (energy/radian^2)
- $K_3$ (energy/radian^3)
- $K_4$ (energy/radian^4)
- $K_5$ (energy/radian^5)
- $K_6$ (energy/radian^6)

The bond-bond and bond-angle terms remain unchanged.

## 20.8.4 Restrictions

This angle style can only be used if LAMMPS was built with the CLASS2 package. For the `class2/p6` style LAMMPS needs to be built with the USER-MOFFF package. See the Build package doc page for more info.

## 20.8.5 Related commands

`angle_coeff`

```
angle_style cosine
```

20.11.2 Examples

```
angle_style cosine
angle_coeff * 75.0
```

20.11.3 Description

The `cosine` angle style uses the potential

\[ E = K [1 + \cos(\theta)] \]

where \( K \) is defined for each angle type.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

---

20.9. angle_style cosine command 1927
20.11.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

20.11.5 Related commands

angle_coeff

Default: none

20.12 angle_style cosine/buck6d command

20.12.1 Syntax

```
angle_style cosine/buck6d
```

20.12.2 Examples

```
angle_style cosine/buck6d
angle_coeff 1 cosine/buck6d 1.978350 4 180.000000
```

20.12.3 Description

The `cosine/buck6d` angle style uses the potential

\[ E = K [1 + \cos(n\theta - \theta_0)] \]

where \( K \) is the energy constant, \( n \) is the periodic multiplicity and \( \theta_0 \) is the equilibrium angle.

The coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands in the following order:

- \( K \) (energy)
- \( n \)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally.

Additional to the cosine term the `cosine/buck6d` angle style computes the short range (vdW) interaction belonging to the `pair_style buck6d` between the end atoms of the angle. For this reason this angle style only works in combination with the `pair_style buck6d` styles and needs the `special_bonds` 1-3 interactions to be weighted 0.0 to prevent double counting.
20.12.4 Restrictions

cosine/buck6d can only be used in combination with the pair_style buck6d style and with a special_bonds 0.0 weighting of 1-3 interactions.

This angle style can only be used if LAMMPS was built with the USER-MOFFF package. See the Build package doc page for more info.

20.14.5 Related commands

angle_coeff, angle_style cosine/squared

Default: none

20.15 angle_style cosine/periodic command

20.16 angle_style cosine/periodic/omp command

20.16.1 Syntax

angle_style cosine/periodic

20.16.2 Examples

angle_style cosine/periodic
angle_coeff * 75.0 1 6

20.16.3 Description

The cosine/periodic angle style uses the following potential, which is commonly used in the DREIDING force field, particularly for organometallic systems where $n = 4$ might be used for an octahedral complex and $n = 3$ might be used for a trigonal center:

$$E = C \left[ 1 - B(-1)^n \cos(n\theta) \right]$$

where $C$, $B$ and $n$ are coefficients defined for each angle type.

See (Mayo) for a description of the DREIDING force field

The following coefficients must be defined for each angle type via the angle_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- $C$ (energy)
• $B = 1$ or -1

• $n = 1, 2, 3, 4, 5$ or 6 for periodicity

Note that the prefactor $C$ is specified and not the overall force constant $K = \frac{C}{n^2}$. When $B = 1$, it leads to a minimum for the linear geometry. When $B = -1$, it leads to a maximum for the linear geometry.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.18.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER-MISC package.

20.18.5 Related commands

`angle_coeff`, `angle_style cosine/shift/exp`

Default: none
20.19 angle_style cosine/shift/exp command

20.20 angle_style cosine/shift/exp/omp command

20.20.1 Syntax

angle_style cosine/shift/exp

20.20.2 Examples

angle_style cosine/shift/exp
angle_coeff * 10.0 45.0 2.0

20.20.3 Description

The **cosine/shift/exp** angle style uses the potential

\[ E = -U_{\text{min}} \frac{e^{-aU(\theta, \theta_0)} - 1}{e^a - 1} \]

with \( U(\theta, \theta_0) = -0.5 (1 + \cos(\theta - \theta_0)) \)

where \( U_{\text{min}}, \theta, \) and \( a \) are defined for each angle type.

The potential is bounded between \([-U_{\text{min}}, 0]\) and the minimum is located at the angle \( \theta_0 \). The \( a \) parameter can be both positive or negative and is used to control the spring constant at the equilibrium.

The spring constant is given by \( k = A \exp(A) U_{\text{min}}/[2(\exp(a) - 1)] \). For \( a > 3 \), \( \frac{k}{U_{\text{min}}} = \frac{a}{2} \) to better than 5\% relative error. For negative values of the \( a \) parameter, the spring constant is essentially zero, and anharmonic terms takes over. The potential is furthermore well behaved in the limit \( a \to 0 \), where it has been implemented to linear order in \( a \) for \( a < 0.001 \). In this limit the potential reduces to the cosineshifted potential.

The following coefficients must be defined for each angle type via the **angle_coeff** command as in the example above, or in the data file or restart files read by the **read_data** or **read_restart** commands:

- \( U_{\text{min}} \) (energy)
- \( \theta \) (angle)

20.23 angle_style cross command

20.23.1 Syntax

```
angle_style cross
```

20.23.2 Examples

```
angle_style cross
angle_coeff 1 200.0 100.0 100.0 1.25 1.25 107.0
```

20.23.3 Description

The `cross` angle style uses a potential that couples the bond stretches of a bend with the angle stretch of that bend:

\[
E = K_{SS} (r_{12} - r_{12,0}) (r_{32} - r_{32,0}) + K_{BS0} (r_{12} - r_{12,0}) (\theta - \theta_0) + K_{BS1} (r_{32} - r_{32,0}) (\theta - \theta_0)
\]

where \( r_{12,0} \) is the rest value of the bond length between atom 1 and 2, \( r_{32,0} \) is the rest value of the bond length between atom 3 and 2, and \( \theta_0 \) is the rest value of the angle. \( K_{SS} \) is the force constant of the bond stretch-bond stretch term and \( K_{BS0} \) and \( K_{BS1} \) are the force constants of the bond stretch-angle stretch terms.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K_{SS} \) (energy/distance²)
- \( K_{BS0} \) (energy/distance/rad)
- \( K_{BS1} \) (energy/distance/rad)
- \( r_{12,0} \) (distance)
- \( r_{32,0} \) (distance)
• $\theta_0$ (degrees)

$\theta_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence the units of $K_{BS0}$ and $K_{BS1}$ are in energy/distance/radian.

20.23.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER_YAFF package. See the Build package doc page for more info.

20.23.5 Related commands

angle_coeff

Default: none

20.24 angle_style dipole command

20.25 angle_style dipole/omp command

20.25.1 Syntax

angle_style dipole

20.25.2 Examples

angle_style dipole
angle_coeff 6 2.1 180.0

20.25.3 Description

The dipole angle style is used to control the orientation of a dipolar atom within a molecule (Orsi). Specifically, the dipole angle style restrains the orientation of a point dipole $\mu_j$ (embedded in atom $j$) with respect to a reference (bond) vector $\vec{r}_{ij} = \vec{r}_i - \vec{r}_j$, where $i$ is another atom of the same molecule (typically, $i$ and $j$ are also covalently bonded).

It is convenient to define an angle gamma between the ‘free’ vector $\mu_j$ and the reference (bond) vector $\vec{r}_{ij}$:

$$\cos \gamma = \frac{\mu_j \cdot \vec{r}_{ij}}{\mu_j \vec{r}_{ij}}$$

The dipole angle style uses the potential:

$$E = K(\cos \gamma - \cos \gamma_0)^2$$

where $K$ is a rigidity constant and $\gamma_0$ is an equilibrium (reference) angle.

The torque on the dipole can be obtained by differentiating the potential using the ‘chain rule’ as in appendix C.3 of (Allen):

$$\vec{T}_j = \frac{2K(\cos \gamma - \cos \gamma_0)}{\mu_j r_{ij}} \vec{r}_{ij} \times \mu_j$$
Example: if $\gamma_0$ is set to 0 degrees, the torque generated by the potential will tend to align the dipole along the reference direction defined by the (bond) vector $r_{ij}$ (in other words, $\mu_j$ is restrained to point towards atom $i$).

The dipolar torque $\vec{T}_j$ must be counterbalanced in order to conserve the local angular momentum. This is achieved via an additional force couple generating a torque equivalent to the opposite of $\vec{T}_j$:

$$-\vec{T}_j = r_{ij} \times \vec{F}_i$$

where $\vec{F}_i$ and $\vec{F}_j$ are applied on atoms $i$ and $j$, respectively.

The following coefficients must be defined for each angle type via the angle_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- $K$ (energy)
- $\gamma_0$ (degrees)

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.25.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

**Note:** In the “Angles” section of the data file, the atom ID $j$ defining the direction of the dipole vector to restrain must come before the atom ID of the reference atom $i$. A third atom ID $k$ must also be provided to comply with the requirement of a valid angle definition. This atom ID $k$ should be chosen to be that of an atom bonded to atom $i$ to avoid errors with “lost angle atoms” when running in parallel. Since the LAMMPS code checks for valid angle definitions, cannot use the same atom ID of either $i$ or $j$ (this was allowed and recommended with older LAMMPS versions).

The newton command for intramolecular interactions must be “on” (which is the default except when using some accelerator packages).

This angle style should not be used with SHAKE.

20.33.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

20.33.5 Related commands

`angle_coeff`

Default: none
20.34 angle_style hybrid command

20.34.1 Syntax

```
angle_style hybrid style1 style2 ...
```

- style1, style2 = list of one or more angle styles

20.34.2 Examples

```
angle_style hybrid harmonic cosine
angle_coeff 1 harmonic 80.0 30.0
angle_coeff 2* cosine 50.0
```

20.34.3 Description

The `hybrid` style enables the use of multiple angle styles in one simulation. An angle style is assigned to each angle type. For example, angles in a polymer flow (of angle type 1) could be computed with a `harmonic` potential and angles in the wall boundary (of angle type 2) could be computed with a `cosine` potential. The assignment of angle type to style is made via the `angle_coeff` command or in the data file.

In the `angle_coeff` commands, the name of an angle style must be added after the angle type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 `angle_coeff` commands set angles of angle type 1 to be computed with a `harmonic` potential with coefficients 80.0, 30.0 for $K$, $\theta_0$. All other angle types ($2 - N$) are computed with a `cosine` potential with coefficient 50.0 for $K$.

If angle coefficients are specified in the data file read via the `read_data` command, then the same rule applies. E.g. “harmonic” or “cosine”, must be added after the angle type, for each line in the “Angle Coeffs” section, e.g.

```
Angle Coeffs
1 harmonic 80.0 30.0
2 cosine 50.0
...
```

If `class2` is one of the angle hybrid styles, the same rule holds for specifying additional BondBond (and BondAngle) coefficients either via the input script or in the data file. I.e. `class2` must be added to each line after the angle type. For lines in the BondBond (or BondAngle) section of the data file for angle types that are not `class2`, you must use an angle style of `skip` as a placeholder, e.g.

```
BondBond Coeffs
1 skip
2 class2 3.6512 1.0119 1.0119
...
```

Note that it is not necessary to use the angle style `skip` in the input script, since BondBond (or BondAngle) coefficients need not be specified at all for angle types that are not `class2`.

An angle style of `none` with no additional coefficients can be used in place of an angle style, either in a input script `angle_coeff` command or in the data file, if you desire to turn off interactions for specific angle types.
20.34.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

Unlike other angle styles, the hybrid angle style does not store angle coefficient info for individual sub-styles in a binary restart files. Thus when restarting a simulation from a restart file, you need to re-specify angle_coeff commands.

20.34.5 Related commands

angle_coeff

```
angle_style mm3
```

20.35.2 Examples

```
angle_style mm3
angle_coeff 1 100.0 107.0
```

20.35.3 Description

The mm3 angle style uses the potential that is anharmonic in the angle as defined in (Allinger)

\[ E = K(\theta - \theta_0)^2 \left[ 1 - 0.014(\theta - \theta_0) + 5.6(10)^{-5}(\theta - \theta_0)^2 - 7.0(10)^{-7}(\theta - \theta_0)^3 + 9(10)^{-10}(\theta - \theta_0)^4 \right] \]

where \( \theta_0 \) is the equilibrium value of the angle, and \( K \) is a prefactor. The anharmonic prefactors have units \( \text{deg}^{-n} \), for example \(-0.014 \text{deg}^{-1}, 5.6 \cdot 10^{-5} \text{deg}^{-2}, \ldots \)

The following coefficients must be defined for each angle type via the angle_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy/radian^2)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence the units of \( K \) are in energy/radian^2.
20.35.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER_YAFF package. See the Build package doc page for more info.

```
angle_style quartic
angle_coeff 1 129.1948 56.8726 -25.9442 -14.2221
```

20.38.3 Description

The quartic angle style uses the potential

\[ E = K_2(\theta - \theta_0)^2 + K_3(\theta - \theta_0)^3 + K_4(\theta - \theta_0)^4 \]

where \( \theta_0 \) is the equilibrium value of the angle, and \( K \) is a prefactor. Note that the usual \( 1/2 \) factor is included in \( K \).

The following coefficients must be defined for each angle type via the \texttt{angle_coeff} command as in the example above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands:

- \( \theta_0 \) (degrees)
- \( K_2 \) (energy/radian^2)
- \( K_3 \) (energy/radian^3)
- \( K_4 \) (energy/radian^4)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence the units of \( K \) are in energy/radian^2.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \texttt{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.
20.38.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER_MISC package. See the Build package doc page for more info.

```
angle_style  sdk
angle_style  sdk/omp
```

20.40.2 Examples

```
angle_style  sdk
angle_coeff   1  300.0  107.0
```

20.40.3 Description

The \textit{sdk} angle style is a combination of the harmonic angle potential,

\[ E = K(\theta - \theta_0)^2 \]

where \( \theta_0 \) is the equilibrium value of the angle and \( K \) a prefactor, with the repulsive part of the non-bonded \textit{lj/sdk} pair style between the atoms 1 and 3. This angle potential is intended for coarse grained MD simulations with the CMM parameterization using the \textit{pair_style lj/sdk}. Relative to the \textit{pair_style lj/sdk}, however, the energy is shifted by \( \epsilon \), to avoid sudden jumps. Note that the usual 1/2 factor is included in \( K \).

The following coefficients must be defined for each angle type via the \textit{angle_coeff} command as in the example above:

- \( K \) (energy/radian\(^2\))
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence the units of \( K \) are in energy/radian\(^2\). The also required \textit{lj/sdk} parameters will be extracted automatically from the \textit{pair_style}.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page.

Chapter 20. Angle Styles
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

### 20.41 angle_style table command

#### 20.42 angle_style table/omp command

#### 20.42.1 Syntax

```
angle_style table style N
```

- style = linear or spline = method of interpolation
- N = use N values in table

#### 20.42.2 Examples

```
angle_style table linear 1000
angle_coeff 3 file.table ENTRY1
```
20.42.3 Description

Style table creates interpolation tables of length \( N \) from angle potential and derivative values listed in a file(s) as a function of angle. The files are read by the angle_coeff command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and derivative values at each of \( N \) angles. During a simulation, these tables are used to interpolate energy and force values on individual atoms as needed. The interpolation is done in one of 2 styles: linear or spline.

For the linear style, the angle is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation.

For the spline style, a cubic spline coefficients are computed and stored at each of the \( N \) values in the table. The angle is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or derivative.

The following coefficients must be defined for each angle type via the angle_coeff command as in the example above.

- filename
- keyword

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# Angle potential for harmonic (one or more comment or blank lines)

HAM
N 181 FP 0 0 EQ 90.0  
N 181 FP 0 0  
1 0.0 200.5 2.5  
2 1.0 198.0 2.5  
...  
181 180.0 0.0 0.0
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the angle_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the \( N \) specified in the angle_style table command. Let Ntable = \( N \) in the angle_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and force for individual angles and their atoms. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile.

The “FP” parameter is optional. If used, it is followed by two values fplo and fphi, which are the second derivatives at the innermost and outermost angle settings. These values are needed by the spline construction routines. If not specified by the “FP” parameter, they are estimated (less accurately) by the first two and last two derivative values in the table.

The “EQ” parameter is also optional. If used, it is followed by a the equilibrium angle value, which is used, for example, by the fix shake command. If not used, the equilibrium angle is set to 180.0.
Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the angle value (in degrees), the third value is the energy (in energy units), and the fourth is -dE/d(theta) (also in energy units). The third term is the energy of the 3-atom configuration for the specified angle. The last term is the derivative of the energy with respect to the angle (in degrees, not radians). Thus the units of the last term are still energy, not force. The angle values must increase from one line to the next. The angle values must also begin with 0.0 and end with 180.0, i.e. span the full range of possible angles.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix} command-line switch when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

\textbf{Restart info:}

This angle style writes the settings for the “angle_style table” command to binary restart files, so a angle_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, angle_coeff commands do need to be specified in the restart input script.

\textbf{20.42.4 Restrictions}

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the \textit{Build package} doc page for more info.

\textbf{20.42.5 Related commands}

\textit{angle_coeff}

\textbf{Default:} none

\textbf{20.43 angle_style zero command}

\textbf{20.43.1 Syntax}

\begin{verbatim}
angle_style zero *nocoeff*
\end{verbatim}
20.43.2 Examples

```
angle_style zero
angle_style zero nocoeff
angle_coeff *
angle_coeff * 120.0
```

20.43.3 Description

Using an angle style of zero means angle forces and energies are not computed, but the geometry of angle triplets is still accessible to other commands.

As an example, the `compute angle/local` command can be used to compute the theta values for the list of triplets of angle atoms listed in the data file read by the `read_data` command. If no angle style is defined, this command cannot be used.

The optional `nocoeff` flag allows to read data files with AngleCoeff section for any angle style. Similarly, any `angle_coeff` commands will only be checked for the angle type number and the rest ignored.

Note that the `angle_coeff` command must be used for all angle types. If specified, there can be only one value, which is going to be used to assign an equilibrium angle, e.g. for use with `fix shake`.

20.43.4 Restrictions

none

20.43.5 Related commands

`angle_style none`

CHAPTER TWENTYONE

DIHEDRAL STYLES

21.1 dihedral_style charmm command

21.2 dihedral_style charmm/intel command

21.3 dihedral_style charmm/kk command

21.4 dihedral_style charmm/omp command

21.5 dihedral_style charmmfsw command

21.5.1 Syntax

\[
\text{dihedral_style} \ style
\]

- style = charmm or charmmfsw

21.5.2 Examples

\[
\begin{align*}
\text{dihedral_style} & \ \text{charmm} \\
\text{dihedral_style} & \ \text{charmmfsw} \\
\text{dihedral_coeff} & \ 1 \ 0.2 \ 1 \ 180 \ 1.0 \\
\text{dihedral_coeff} & \ 2 \ 1.8 \ 1 \ 0 \ 1.0 \\
\text{dihedral_coeff} & \ 1 \ 3.1 \ 2 \ 180 \ 0.5
\end{align*}
\]

21.5.3 Description

The \textit{charmm} and \textit{charmmfsw} dihedral styles use the potential

\[
E = K[1 + \cos(n\phi - d)]
\]

See \textit{(MacKerell)} for a description of the CHARMM force field. This dihedral style can also be used for the AMBER force field (see comment on weighting factors below). See \textit{(Cornell)} for a description of the AMBER force field.
Note: The newer charmmfsw style was released in March 2017. We recommend it be used instead of the older charmm style when running a simulation with the CHARMM force field, either with long-range Coulombics or a Coulombic cutoff, via the pair_style lj/charmmfsw/coul/long and pair_style lj/charmmfsw/coul/charmmfsh commands respectively. Otherwise the older charmm style is fine to use. See the discussion below and more details on the pair_style charmm doc page.

The following coefficients must be defined for each dihedral type via the dihedral_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- $K$ (energy)
- $n$ (integer $\geq 0$)
- $d$ (integer value of degrees)
- weighting factor (1.0, 0.5, or 0.0)

The weighting factor is required to correct for double counting pairwise non-bonded Lennard-Jones interactions in cyclic systems or when using the CHARMM dihedral style with non-CHARMM force fields. With the CHARMM dihedral style, interactions between the first and fourth atoms in a dihedral are skipped during the normal non-bonded force computation and instead evaluated as part of the dihedral using special epsilon and sigma values specified with the pair_coeff command of pair styles that contain “lj/charm” (e.g. pair_style lj/charm/coul/long) In 6-membered rings, the same 1-4 interaction would be computed twice (once for the clockwise 1-4 pair in dihedral 1-2-3-4 and once in the counterclockwise dihedral 1-6-5-4) and thus the weighting factor has to be 0.5 in this case. In 4-membered or 5-membered rings, the 1-4 dihedral also is counted as a 1-2 or 1-3 interaction when going around the ring in the opposite direction and thus the weighting factor is 0.0, as the 1-2 and 1-3 exclusions take precedence.

Note that this dihedral weighting factor is unrelated to the scaling factor specified by the special_bonds command which applies to all 1-4 interactions in the system. For CHARMM force fields, the special_bonds 1-4 interaction scaling factor should be set to 0.0. Since the corresponding 1-4 non-bonded interactions are computed with the dihedral. This means that if any of the weighting factors defined as dihedral coefficients (fourth coeff above) are non-zero, then you must use a pair style with “lj/charm” and set the special_bonds 1-4 scaling factor to 0.0 (which is the default). Otherwise 1-4 non-bonded interactions in dihedrals will be computed twice.

For simulations using the CHARMM force field with a Coulombic cutoff, the difference between the charmm and charmmfsw styles is in the computation of the 1-4 non-bond interactions, though only if the distance between the two atoms is within the switching region of the pairwise potential defined by the corresponding CHARMM pair style, i.e. within the outer cutoff specified for the pair style. The charmmfsw style should only be used when using the corresponding pair_style lj/charmmfsw/coul/charmmfsw or pair_style lj/charmmfsw/coul/long commands. Use the charmm style with the older pair_style commands that have just “charm” in their style name. See the discussion on the CHARMM pair_style doc page for details.

Note that for AMBER force fields, which use pair styles with “lj/cut”, the special_bonds 1-4 scaling factor should be set to the AMBER defaults (1/2 and 5/6) and all the dihedral weighting factors (fourth coeff above) must be set to 0.0. In this case, you can use any pair style you wish, since the dihedral does not need any Lennard-Jones parameter information and will not compute any 1-4 non-bonded interactions. Likewise the charmm or charmmfsw styles are identical in this case since no 1-4 non-bonded interactions are computed.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

### 21.5.4 Restrictions

When using `run_style respa`, these dihedral styles must be assigned to the same r-RESPA level as `pair` or `outer`.

When used in combination with CHARMM pair styles, the 1-4 `special_bonds` scaling factors must be set to 0.0. Otherwise non-bonded contributions for these 1-4 pairs will be computed multiple times.

These dihedral styles can only be used if LAMMPS was built with the MOLECULE package. See the `Build package` doc page for more info.

### 21.5.5 Related commands

- `dihedral_coeff`

  **Default:** none

### 21.6 dihedral_style class2 command

### 21.7 dihedral_style class2/omp command

### 21.8 dihedral_style class2/kk command

```

21.6. **dihedral_style class2 command**
21.8.3 Description

The class2 dihedral style uses the potential

\[ E = E_d + E_{mbt} + E_{ebt} + E_{at} + E_{aat} + E_{bb13} \]

\[ E_d = \sum_{n=1}^{3} K_n [1 - \cos(n\phi - \phi_n)] \]

\[ E_{mbt} = (r_{jk} - r_2) \left[ A_1 \cos(\phi) + A_2 \cos(2\phi) + A_3 \cos(3\phi) \right] \]

\[ E_{ebt} = (r_{ij} - r_1) \left[ B_1 \cos(\phi) + B_2 \cos(2\phi) + B_3 \cos(3\phi) \right] +
(r_{kl} - r_3) \left[ C_1 \cos(\phi) + C_2 \cos(2\phi) + C_3 \cos(3\phi) \right] \]

\[ E_{at} = (\theta_{ijk} - \theta_1) \left[ D_1 \cos(\phi) + D_2 \cos(2\phi) + D_3 \cos(3\phi) \right] +
(\theta_{jkl} - \theta_2) \left[ E_1 \cos(\phi) + E_2 \cos(2\phi) + E_3 \cos(3\phi) \right] \]

\[ E_{aat} = M(\theta_{ijk} - \theta_1)(\theta_{jkl} - \theta_2) \cos(\phi) \]

\[ E_{bb13} = N(r_{ij} - r_1)(r_{kl} - r_3) \]

where \( E_d \) is the dihedral term, \( E_{mbt} \) is a middle-bond-torsion term, \( E_{ebt} \) is an end-bond-torsion term, \( E_{at} \) is an angle-torsion term, \( E_{aat} \) is an angle-angle-torsion term, and \( E_{bb13} \) is a bond-bond-13 term.

\( \theta_1 \) and \( \theta_2 \) are equilibrium angles and \( r_1, r_2, \) and \( r_3 \) are equilibrium bond lengths.

See (Sun) for a description of the COMPASS class2 force field.

Coefficients for the \( E_d, E_{mbt}, E_{ebt}, E_{at}, E_{aat}, \) and \( E_{bb13} \) formulas must be defined for each dihedral type via the dihedral_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands.

These are the 6 coefficients for the \( E_d \) formula:

- \( K_1 \) (energy)
- \( \phi_1 \) (degrees)
- \( K_2 \) (energy)
- \( \phi_2 \) (degrees)
- \( K_3 \) (energy)
- \( \phi_3 \) (degrees)

For the \( E_{mbt} \) formula, each line in a dihedral_coeff command in the input script lists 5 coefficients, the first of which is \( mbt \) to indicate they are MiddleBondTorsion coefficients. In a data file, these coefficients should be listed under a MiddleBondTorsion Coeffs heading and you must leave out the \( mbt \), i.e. only list 4 coefficients after the dihedral type.

- \( mbt \)
- \( A_1 \) (energy/distance)
- \( A_2 \) (energy/distance)
- \( A_3 \) (energy/distance)
- \( r_2 \) (distance)

For the \( E_{ebt} \) formula, each line in a dihedral_coeff command in the input script lists 9 coefficients, the first of which is \( ebt \) to indicate they are EndBondTorsion coefficients. In a data file, these coefficients should be listed under a EndBondTorsion Coeffs heading and you must leave out the \( ebt \), i.e. only list 8 coefficients after the dihedral type.

- \( ebt \)
- \( B_1 \) (energy/distance)
• $B_2$ (energy/distance)
• $B_3$ (energy/distance)
• $C_1$ (energy/distance)
• $C_2$ (energy/distance)
• $C_3$ (energy/distance)
• $r_1$ (distance)
• $r_3$ (distance)

For the $E_{at}$ formula, each line in a `dihedral_coeff` command in the input script lists 9 coefficients, the first of which is at to indicate they are AngleTorsion coefficients. In a data file, these coefficients should be listed under a `AngleTorsion Coeffs` heading and you must leave out the at, i.e. only list 8 coefficients after the dihedral type.

• $at$
• $D_1$ (energy/radian)
• $D_2$ (energy/radian)
• $D_3$ (energy/radian)
• $E_1$ (energy/radian)
• $E_2$ (energy/radian)
• $E_3$ (energy/radian)
• $\theta_1$ (degrees)
• $\theta_2$ (degrees)

$\theta_1$ and $\theta_2$ are specified in degrees, but LAMMPS converts them to radians internally; hence the units of $D$ and $E$ are in energy/radian.

For the $E_{aat}$ formula, each line in a `dihedral_coeff` command in the input script lists 4 coefficients, the first of which is aat to indicate they are AngleAngleTorsion coefficients. In a data file, these coefficients should be listed under a `AngleAngleTorsion Coeffs` heading and you must leave out the aat, i.e. only list 3 coefficients after the dihedral type.

• $aat$
• $M$ (energy/radian²)
• $\theta_1$ (degrees)
• $\theta_2$ (degrees)

$\theta_1$ and $\theta_2$ are specified in degrees, but LAMMPS converts them to radians internally; hence the units of $M$ are in energy/radian².

For the $E_{bb13}$ formula, each line in a `dihedral_coeff` command in the input script lists 4 coefficients, the first of which is $bb13$ to indicate they are BondBond13 coefficients. In a data file, these coefficients should be listed under a `BondBond13 Coeffs` heading and you must leave out the $bb13$, i.e. only list 3 coefficients after the dihedral type.

• $bb13$
• $N$ (energy/distance²)
• $r_1$ (distance)
• $r_3$ (distance)
Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. ### 21.8.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the CLASS2 package. See the \textit{Build package} doc page for more info.

### 21.8.5 Related commands

\texttt{dihedral_coeff}

\textbf{Default:} none

### 21.9 \texttt{dihedral\_style cosine/shift/exp command}

### 21.10 \texttt{dihedral\_style cosine/shift/exp/omp command}

#### 21.10.1 Syntax

\begin{verbatim}
\texttt{dihedral\_style cosine/shift/exp}
\end{verbatim}

#### 21.10.2 Examples

\begin{verbatim}
\texttt{dihedral\_style cosine/shift/exp}
\texttt{dihedral\_coeff 1 10.0 45.0 2.0}
\end{verbatim}
21.10.3 Description

The cosine/shift/exp dihedral style uses the potential

\[ E = -U_{\text{min}} \frac{e^{-aU(\theta, \theta_0)} - 1}{e^a - 1} \quad \text{with} \quad U(\theta, \theta_0) = -0.5 (1 + \cos(\theta - \theta_0)) \]

where \( U_{\text{min}}, \theta, \) and \( a \) are defined for each dihedral type.

The potential is bounded between \([ -U_{\text{min}} : 0 ]\) and the minimum is located at the angle \( \theta_0 \). The \( a \) parameter can be both positive or negative and is used to control the spring constant at the equilibrium.

The spring constant is given by \( k = ae^a \frac{U_{\text{min}}}{2(e^a - 1)} \). For \( a > 3 \) and \( \frac{k}{U_{\text{min}}} \approx \frac{a}{2} \) to better than 5% relative error. For negative values of the \( a \) parameter, the spring constant is essentially zero, and anharmonic terms take over. The potential is furthermore well behaved in the limit \( a \to 0 \), where it has been implemented to linear order in \( a \) for \( a < 0.001 \).

The following coefficients must be defined for each dihedral type via the \textit{dihedral_coeff} command as in the example above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands:

- \( U_{\text{min}} \) (energy)
- \( \theta \) (angle)
- \( a \) (real number)

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix} command-line switch when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

21.10.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the USER-MISC package. See the \textit{Build package} doc page for more info.

21.17.1 Syntax

```
dihedral_style harmonic
```

21.17.2 Examples

```
dihedral_style harmonic
dihedral_coeff 1 80.0 1 2
```

21.17.3 Description

The harmonic dihedral style uses the potential

\[ E = K[1 + d \cos(n\phi)] \]

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy)
- \( d \) (+1 or -1)
- \( n \) (integer \( \geq 0 \))

**Note:** Here are important points to take note of when defining LAMMPS dihedral coefficients for the harmonic style, so that they are compatible with how harmonic dihedrals are defined by other force fields:

- The LAMMPS convention is that the trans position = 180 degrees, while in some force fields trans = 0 degrees.
LAMMPS Documentation

- Some force fields reverse the sign convention on \(d\).
- Some force fields let \(n\) be positive or negative which corresponds to \(d = 1\) or \(d = -1\) for the harmonic style.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

1960 Chapter 21. Dihedral Styles
21.19.3 Description

The helix dihedral style uses the potential

\[ E = A[1 - \cos(\theta)] + B[1 + \cos(3\theta)] + C[1 + \cos(\theta + \frac{\pi}{4})] \]

This coarse-grain dihedral potential is described in (Guo). For dihedral angles in the helical region, the energy function is represented by a standard potential consisting of three minima, one corresponding to the trans (t) state and the other to gauche states (g+ and g-). The paper describes how the \( A \), \( B \) and, \( C \) parameters are chosen so as to balance secondary (largely driven by local interactions) and tertiary structure (driven by long-range interactions).

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( A \) (energy)
- \( B \) (energy)
- \( C \) (energy)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. 21.19.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

21.19.5 Related commands

dihedral_coeff

Default: none

21.20 dihedral_style hybrid command

21.20.1 Syntax

```
dihedral_style hybrid style1 style2 ...
```

- style1, style2 = list of one or more dihedral styles

21.20.2 Examples

```
dihedral_style hybrid harmonic helix
dihedral_coeff 1 harmonic 6.0 1 3
dihedral_coeff 2* helix 10 10 10
```

21.20.3 Description

The hybrid style enables the use of multiple dihedral styles in one simulation. An dihedral style is assigned to each dihedral type. For example, dihedrals in a polymer flow (of dihedral type 1) could be computed with a harmonic potential and dihedrals in the wall boundary (of dihedral type 2) could be computed with a helix potential. The assignment of dihedral type to style is made via the dihedral_coeff command or in the data file. In the dihedral_coeff commands, the name of a dihedral style must be added after the dihedral type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 dihedral_coeff commands set dihedrals of dihedral type 1 to be computed with a harmonic potential with coefficients 6.0, 1, 3 for K, d, n. All other dihedral types (2-N) are computed with a helix potential with coefficients 10, 10, 10 for A, B, C.

If dihedral coefficients are specified in the data file read via the read_data command, then the same rule applies. E.g. “harmonic” or “helix”, must be added after the dihedral type, for each line in the “Dihedral Coeffs” section, e.g.

```
Dihedral Coeffs
1  harmonic  6.0   1   3
2  helix 10 10 10
...  
```

If class2 is one of the dihedral hybrid styles, the same rule holds for specifying additional AngleTorsion (and End-BondTorsion, etc) coefficients either via the input script or in the data file. I.e. class2 must be added to each line after the dihedral type. For lines in the AngleTorsion (or EndBondTorsion, etc) section of the data file for dihedral types that are not class2, you must use an dihedral style of skip as a placeholder, e.g.

```
AngleTorsion Coeffs
1 skip
2 class2 1.0 1.0 1.0 3.0 3.0 3.0 30.0 50.0
...  
```

Note that it is not necessary to use the dihedral style skip in the input script, since AngleTorsion (or EndBondTorsion, etc) coefficients need not be specified at all for dihedral types that are not class2.

A dihedral style of none with no additional coefficients can be used in place of a dihedral style, either in a input script dihedral_coeff command or in the data file, if you desire to turn off interactions for specific dihedral types.
21.20.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

Unlike other dihedral styles, the hybrid dihedral style does not store dihedral coefficient info for individual sub-styles in a binary restart files. Thus when restarting a simulation from a restart file, you need to re-specify dihedral_coeff commands.

21.20.5 Related commands

dihedral_coeff

Default: none

21.21 dihedral_style multi/harmonic command

21.22 dihedral_style multi/harmonic/omp command

21.22.1 Syntax

```
dihedral_style multi/harmonic
```

21.22.2 Examples

```
dihedral_style multi/harmonic
dihedral_coeff 1 20 20 20 20 20
```

21.22.3 Description

The multi/harmonic dihedral style uses the potential

\[ E = \sum_{n=1,5} A_n \cos^{n-1}(\phi) \]

The following coefficients must be defined for each dihedral type via the dihedral_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( A_1 \) (energy)
- \( A_2 \) (energy)
- \( A_3 \) (energy)
- \( A_4 \) (energy)
- \( A_5 \) (energy)

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

21.22.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

21.31.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER_MISC package. See the *Build package* doc page for more info.

21.31.5 Related commands

`dihedral_coeff`

*Default:* none
21.32 dihedral_style spherical command

21.32.1 Syntax

```
dihedral_style spherical
```

21.32.2 Examples

```
dihedral_coeff 1 1 286.1 1 124 1 1 90.0 0 1 90.0 0
```

```
dihedral_coeff 1 3 69.3 1 93.9 1 1 90 0 1 90 0 49.1 0 0.00 0 1 74.4 1 0 0.00 0 25.2 0 0.00 0 0 0.00 0 1 48.1 1
```

21.32.3 Description

The spherical dihedral style uses the potential:

\[
E(\phi, \theta_1, \theta_2) = \sum_{i=1}^{N} C_i \Phi_i(\phi) \Theta_{1i}(\theta_1) \Theta_{2i}(\theta_2)
\]

\[
\Phi_i(\phi) = u_i - \cos((\phi - a_i)K_i)
\]

\[
\Theta_{1i}(\theta_1) = v_i - \cos((\theta_1 - b_i)L_i)
\]

\[
\Theta_{2i}(\theta_2) = w_i - \cos((\theta_2 - c_i)M_i)
\]

For this dihedral style, the energy can be any function that combines the 4-body dihedral-angle (\(\phi\)) and the two 3-body bond-angles (\(\theta_1\), \(\theta_2\)). For this reason, there is usually no need to define 3-body “angle” forces separately for the atoms participating in these interactions. It is probably more efficient to incorporate 3-body angle forces into the dihedral interaction even if it requires adding additional terms to the expansion (as was done in the second example). A careful choice of parameters can prevent singularities that occur with traditional force-fields whenever \(\theta_1\) or \(\theta_2\) approach 0 or 180 degrees.

The last example above corresponds to an interaction with a single energy minima located near \(\phi = 93.9\), \(\theta_1 = 74.4\), \(\theta_2 = 48.1\) degrees, and it remains numerically stable at all angles (\(\phi\), \(\theta_1\), \(\theta_2\)). In this example, the coefficients 49.1, and 25.2 can be physically interpreted as the harmonic spring constants for \(\theta_1\) and \(\theta_2\) around their minima. The coefficient 69.3 is the harmonic spring constant for \(\phi\) after division by \(\sin(74.4)\)\(\sin(48.1)\) (the minima positions for \(\theta_1\) and \(\theta_2\)).

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the Dihedral Coeffs section of a data file read by the `read_data` command:

- \(n\) (integer \(\geq 1\))
- \(C_1\) (energy)
- \(K_1\) (typically an integer)
- \(a_1\) (degrees)
• $u_1$ (typically 0.0 or 1.0)
• $L_1$ (typically an integer)
• $b_1$ (degrees, typically 0.0 or 90.0)
• $v_1$ (typically 0.0 or 1.0)
• $M_1$ (typically an integer)
• $c_1$ (degrees, typically 0.0 or 90.0)
• $w_1$ (typically 0.0 or 1.0)
• [...] 
• $C_n$ (energy)
• $K_n$ (typically an integer)
• $a_n$ (degrees)
• $u_n$ (typically 0.0 or 1.0)
• $L_n$ (typically an integer)
• $b_n$ (degrees, typically 0.0 or 90.0)
• $v_n$ (typically 0.0 or 1.0)
• $M_n$ (typically an integer)
• $c_n$ (degrees, typically 0.0 or 90.0)
• $w_n$ (typically 0.0 or 1.0)

21.32.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the USER_MISC package. See the Build package doc page for more info.

21.32.5 Related commands

dihedral_coeff

```
dihedral_style  table spline 400
dihedral_style  table linear 1000
dihedral_coeff  1 file.table DIH_TABLE1
dihedral_coeff  2 file.table DIH_TABLE2
```

21.34.3 Description

The `table` dihedral style creates interpolation tables of length \( N_{table} \) from dihedral potential and derivative values listed in a file(s) as a function of the dihedral angle “\( \phi \)”. The files are read by the `dihedral_coeff` command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and derivative values at each of \( N_{table} \) dihedral angles. During a simulation, these tables are used to interpolate energy and force values on individual atoms as needed. The interpolation is done in one of 2 styles: `linear` or `spline`.

For the `linear` style, the dihedral angle (\( \phi \)) is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation.

For the `spline` style, cubic spline coefficients are computed and stored at each of the \( N_{table} \) evenly-spaced values in the interpolated table. For a given dihedral angle (\( \phi \)), the appropriate coefficients are chosen from this list, and a cubic polynomial is used to compute the energy and the derivative at this angle.

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above.

- `filename`
- `keyword`

The `filename` specifies a file containing tabulated energy and derivative values. The `keyword` specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments). It can begin with one or more comment or blank lines.

```
# Table of the potential and its negative derivative
DIH_TABLE1 (keyword is the first text on line)
N 30 DEGREES (N, NOF, DEGREES, RADIANS, CHECKU/F)

3  -144.0 -1.62956100432
...  
30  180.0 -0.707106781187
```

21.34. dihedral_style table/omp command
A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the `dihedral_coeff` command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the angle value, the third value is the energy (in energy units), and the fourth is -dE/d(ϕ) also in energy units. The third term is the energy of the 4-atom configuration for the specified angle. The fourth term (when present) is the negative derivative of the energy with respect to the angle (in degrees, or radians depending on whether the user selected DEGREES or RADIANS). Thus the units of the last term are still energy, not force. The dihedral angle values must increase from one line to the next.

Dihedral table splines are cyclic. There is no discontinuity at 180 degrees (or at any other angle). Although in the examples above, the angles range from -180 to 180 degrees, in general, the first angle in the list can have any value (positive, zero, or negative). However the range of angles represented in the table must be strictly less than 360 degrees (2π radians) to avoid angle overlap. (You may not supply entries in the table for both 180 and -180, for example.) If the user’s table covers only a narrow range of dihedral angles, strange numerical behavior can occur in the large remaining gap.

**Parameters:**

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the `dihedral_style table` command. Let Ntable be the number of table entries requested dihedral_style command, and let Nfile be the parameter following “N” in the tabulated file (“30” in the sparse example above). What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at Ntable different points (which are evenly spaced over a 360 degree range, even if the angles in the file are not). The resulting tables of length Ntable are then used as described above, when computing energy and force for individual dihedral angles and their atoms. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively nopreliminary interpolation), you should set Ntable = Nfile. To insure the nodal points in the user’s file are aligned with the interpolated table entries, the angles in the table should be integer multiples of 360/Ntable degrees, or 2*PI/Ntable radians (depending on your choice of angle units).

The optional “NOF” keyword allows the user to omit the forces (negative energy derivatives) from the table file (normally located in the fourth column). In their place, forces will be calculated automatically by differentiating the potential energy function indicated by the third column of the table (using either linear or spline interpolation).

The optional “DEGREES” keyword allows the user to specify angles in degrees instead of radians (default).

The optional “RADIANS” keyword allows the user to specify angles in radians instead of degrees. (Note: This changes the way the forces are scaled in the fourth column of the data file.)

The optional “CHECKU” keyword is followed by a filename. This allows the user to save all of the Ntable different entries in the interpolated energy table to a file to make sure that the interpolated function agrees with the user’s expectations. (Note: You can temporarily increase the Ntable parameter to a high value for this purpose. “Ntable” is explained above.)

The optional “CHECKF” keyword is analogous to the “CHECKU” keyword. It is followed by a filename, and it allows the user to check the interpolated force table. This option is available even if the user selected the “NOF” option.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

**Restart info:**

This dihedral style writes the settings for the “dihedral_style table” command to binary restart files, so a dihedral_style command does not need to be specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, dihedral_coeff commands do need to be specified in the restart input script.

### 21.34.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

### 21.34.5 Related commands

*dihedral_coeff*

**Default:** none

### 21.35 dihedral_style table/cut command

#### 21.35.1 Syntax

```plaintext
dihedral_style table/cut style Ntable
```

- `style` = `linear` or `spline` = method of interpolation
- `Ntable` = size of the internal lookup table

#### 21.35.2 Examples

```plaintext
dihedral_style table/cut spline 400
dihedral_style table/cut linear 1000
dihedral_coeff 1 aat 1.0 177 180 file.table DIH_TABLE1
dihedral_coeff 2 aat 0.5 170 180 file.table DIH_TABLE2
```
21.35.3 Description

The table/cut dihedral style creates interpolation tables of length Ntable from dihedral potential and derivative values listed in a file(s) as a function of the dihedral angle “phi”. In addition, an analytic cutoff that is quadratic in the bond-angle (theta) is applied in order to regularize the dihedral interaction. The dihedral table files are read by the dihedral_coeff command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and derivative values at each of Ntable dihedral angles. During a simulation, these tables are used to interpolate energy and force values on individual atoms as needed. The interpolation is done in one of 2 styles: linear or spline.

For the linear style, the dihedral angle (phi) is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation.

For the spline style, cubic spline coefficients are computed and stored at each of the Ntable evenly-spaced values in the interpolated table. For a given dihedral angle (phi), the appropriate coefficients are chosen from this list, and a cubic polynomial is used to compute the energy and the derivative at this angle.

The following coefficients must be defined for each dihedral type via the dihedral_coeff command as in the example above.

- style (aat)
- cutoff prefactor
- cutoff angle1
- cutoff angle2
- filename
- keyword

The cutoff dihedral style uses a tabulated dihedral interaction with a cutoff function:

\[
f(\theta) = K \quad \theta < \theta_1
\]

\[
f(\theta) = K \left( 1 - \frac{(\theta - \theta_1)^2}{(\theta_2 - \theta_1)^2} \right) \quad \theta_1 < \theta < \theta_2
\]

The cutoff specifies an prefactor to the cutoff function. While this value would ordinarily equal 1 there may be situations where the value should change.

The cutoff \(\theta_1\) specifies the angle (in degrees) below which the dihedral interaction is unmodified, i.e. the cutoff function is 1.

The cutoff function is applied between \(\theta_1\) and \(\theta_2\), which is the angle at which the cutoff function drops to zero. The value of zero effectively “turns off” the dihedral interaction.

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments). It can begin with one or more comment or blank lines.

---

# Table of the potential and its negative derivative

DIH_TABLE1

N 30 DEGREES

1 -168.0 -1.40351172223 0.0423346818422

(continues on next page)
A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the dihedral_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the angle value, the third value is the energy (in energy units), and the fourth is -dE/d(φ) also in energy units). The third term is the energy of the 4-atom configuration for the specified angle. The fourth term (when present) is the negative derivative of the energy with respect to the angle (in degrees, or radians depending on whether the user selected DEGREES or RADIANS). Thus the units of the last term are still energy, not force. The dihedral angle values must increase from one line to the next.

Dihedral table splines are cyclic. There is no discontinuity at 180 degrees (or at any other angle). Although in the examples above, the angles range from -180 to 180 degrees, in general, the first angle in the list can have any value (positive, zero, or negative). However the range of angles represented in the table must be strictly less than 360 degrees (2π radians) to avoid angle overlap. (You may not supply entries in the table for both 180 and -180, for example.) If the user’s table covers only a narrow range of dihedral angles, strange numerical behavior can occur in the large remaining gap.

**Parameters:**

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the dihedral_style command. Let Nfile be the parameter following “N” in the tabulated file (“30” in the sparse example above). What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at Ntable different points (which are evenly spaced over a 360 degree range, even if the angles in the file are not). The resulting tables of length Ntable are then used as described above, when computing energy and force for individual dihedral angles and their atoms. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively nonpreliminary interpolation), you should set Ntable = Nfile. To insure the nodal points in the user’s file are aligned with the interpolated table entries, the angles in the table should be integer multiples of 360/Ntable degrees, or 2π/Ntable radians (depending on your choice of angle units).

The optional “NOF” keyword allows the user to omit the forces (negative energy derivatives) from the tabulated file (normally located in the fourth column). In their place, forces will be calculated automatically by differentiating the potential energy function indicated by the third column of the table (using either linear or spline interpolation).

The optional “DEGREES” keyword allows the user to specify angles in degrees instead of radians (default).

The optional “RADIANS” keyword allows the user to specify angles in radians instead of degrees. (Note: This

### Example 2: table of the potential. Forces omitted

30 180.0 -0.707106781187 0.0719306095245

LAMMPS Documentation

The LAMMPS documentation page continues with another example.
changes the way the forces are scaled in the fourth column of the data file.)

The optional “CHECKU” keyword is followed by a filename. This allows the user to save all of the \(N_{\text{table}}\) different entries in the interpolated energy table to a file to make sure that the interpolated function agrees with the user’s expectations. (Note: You can temporarily increase the \(N_{\text{table}}\) parameter to a high value for this purpose. “\(N_{\text{table}}\)” is explained above.)

The optional “CHECKF” keyword is analogous to the “CHECKU” keyword. It is followed by a filename, and it allows the user to check the interpolated force table. This option is available even if the user selected the “NOF” option.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

**Restart info:**

This dihedral style writes the settings for the “dihedral_style table/cut” command to binary restart files, so a dihedral_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, dihedral_coeff commands do need to be specified in the restart input script.

### 21.35.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the USER-MISC package. See the *Build package* doc page for more info.

### 21.36 dihedral_style zero command

#### 21.36.1 Syntax

\begin{verbatim}
dihedral_style zero [nocoeff]
\end{verbatim}

#### 21.36.2 Examples

\begin{verbatim}
dihedral_style zero
dihedral_style zero nocoeff
dihedral_coeff *
\end{verbatim}
21.36.3 Description

Using a dihedral style of zero means dihedral forces and energies are not computed, but the geometry of dihedral quadruplets is still accessible to other commands.

As an example, the compute dihedral/local command can be used to compute the theta values for the list of quadruplets of dihedral atoms listed in the data file read by the read_data command. If no dihedral style is defined, this command cannot be used.

The optional nocoeff flag allows to read data files with a DihedralCoeff section for any dihedral style. Similarly, any dihedral_coeff commands will only be checked for the dihedral type number and the rest ignored.

Note that the dihedral_coeff command must be used for all dihedral types, though no additional values are specified.

21.36.4 Restrictions

IMPROPER STYLES

22.1 improper_style class2 command

22.2 improper_style class2/omp command

22.3 improper_style class2/kk command

22.3.1 Syntax

improper_style
class2

22.3.2 Examples

improper_style
class2
improper_coeff 1 100.0 0
improper_coeff * aa 0.0 0.0 0.0 115.06 130.01 115.06

22.3.3 Description

The class2 improper style uses the potential

\[ E = E_i + E_{aa} \]
\[ E_i = K \left[ \chi_{ijkl} + \chi_{kjli} + \chi_{ljik} - \chi_0 \right]^2 / 3 \]
\[ E_{aa} = M_1 (\theta_{ijk} - \theta_1)(\theta_{kjl} - \theta_3) + \\
M_2 (\theta_{ijk} - \theta_1)(\theta_{ijl} - \theta_2) + \\
M_3 (\theta_{ijl} - \theta_2)(\theta_{kjl} - \theta_3) \]

where \( E_i \) is the improper term and \( E_{aa} \) is an angle-angle term. The 3 \( \chi \) terms in \( E_i \) are an average over 3 out-of-plane angles.

The 4 atoms in an improper quadruplet (listed in the data file read by the read_data command) are ordered I,J,K,L. \( \chi_{ijkl} \) refers to the angle between the plane of IJ,K and the plane of J,K,L, and the bond JK lies in both planes. Similarly for \( \chi_{kjli} \) and \( \chi_{ljik} \). Note that atom J appears in the common bonds (JI, JK, JL) of all 3 X terms. Thus J (the second atom in the quadruplet) is the atom of symmetry in the 3 \( \chi \) angles.
The subscripts on the various $\theta$s refer to different combinations of 3 atoms (I,J,K,L) used to form a particular angle. E.g. $\theta_{ijl}$ is the angle formed by atoms I,J,L with J in the middle. $\theta_1$, $\theta_2$, $\theta_3$ are the equilibrium positions of those angles. Again, atom J (the second atom in the quadruplet) is the atom of symmetry in the theta angles, since it is always the center atom.

Since atom J is the atom of symmetry, normally the bonds J-I, J-K, J-L would exist for an improper to be defined between the 4 atoms, but this is not required.

See (Sun) for a description of the COMPASS class2 force field.

Coefficients for the $E_i$ and $E_{aa}$ formulas must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands.

These are the 2 coefficients for the $E_i$ formula:

- $K$ (energy/radian^2)
- $\chi_0$ (degrees)

$\chi_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence the units of K are in energy/radian^2.

For the $E_{aa}$ formula, each line in a `improper_coeff` command in the input script lists 7 coefficients, the first of which is $aa$ to indicate they are AngleAngle coefficients. In a data file, these coefficients should be listed under a `AngleAngle Coeffs` heading and you must leave out the $aa$, i.e. only list 6 coefficients after the improper type.

- $aa$
- $M_1$ (energy/distance)
- $M_2$ (energy/distance)
- $M_3$ (energy/distance)
- $\theta_1$ (degrees)
- $\theta_2$ (degrees)
- $\theta_3$ (degrees)

The theta values are specified in degrees, but LAMMPS converts them to radians internally; hence the units of M are in energy/radian^2.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
22.3.4 Restrictions

This improper style can only be used if LAMMPS was built with the CLASS2 package. See the Build package doc page for more info.

22.3.5 Related commands

improper_coeff

Default: none

22.4 improper_style cossq command

22.5 improper_style cossq/omp command

22.5.1 Syntax

improper_style cossq

22.5.2 Examples

improper_style cossq
improper_coeff 1 4.0 0.0

22.5.3 Description

The cossq improper style uses the potential

\[ E = \frac{1}{2} K \cos^2 (\chi - \chi_0) \]

where \( \chi \) is the improper angle, \( \chi_0 \) is its equilibrium value, and \( K \) is a prefactor.

If the 4 atoms in an improper quadruplet (listed in the data file read by the read_data command) are ordered I,J,K,L then \( \chi \) is the angle between the plane of I,J,K and the plane of J,K,L. Alternatively, you can think of atoms J,K,L as being in a plane, and atom I above the plane, and \( \chi \) as a measure of how far out-of-plane I is with respect to the other 3 atoms.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy)
- \( \chi_0 \) (degrees)
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 22.5.4 Restrictions

This improper style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

### 22.5.5 Related commands

`improper_coeff`

Default: none

### 22.6 improper_style cvff command

### 22.7 improper_style cvff/intel command

### 22.8 improper_style cvff/omp command

#### 22.8.1 Syntax

```
improper_style cvff
```

#### 22.8.2 Examples

```
improper_style cvff
improper_coeff 1 80.0 -1 4
```
22.8.3 Description

The cvff improper style uses the potential

\[ E = K[1 + d \cos(n\phi)] \]

where \( \phi \) is the improper dihedral angle.

If the 4 atoms in an improper quadruplet (listed in the data file read by the `read_data` command) are ordered I,J,K,L then the improper dihedral angle is between the plane of I,J,K and the plane of J,K,L. Note that because this is effectively a dihedral angle, the formula for this improper style is the same as for `dihedral_style harmonic`.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy)
- \( d \) (+1 or -1)
- \( n \) (0,1,2,3,4,6)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

22.8.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the `Build package` doc page for more info.

22.8.5 Related commands

`improper_coeff`

Default: none
22.9 improper_style distance command

22.9.1 Syntax

\texttt{improper_style distance}

22.9.2 Examples

\texttt{improper_style distance improper_coeff 1 80.0 100.0}

22.9.3 Description

The \textit{distance} improper style uses the potential

\[ E = K_2 d^2 + K_4 d^4 \]

where \( d \) is the distance between the central atom and the plane formed by the other three atoms. If the 4 atoms in an improper quadruplet (listed in the data file read by the \texttt{read_data} command) are ordered I,J,K,L then the I-atom is assumed to be the central atom.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the \texttt{improper_coeff} command as in the example above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands:

- \( K_2 \) (energy/distance\(^2\))
- \( K_4 \) (energy/distance\(^4\))
22.9.4 Restrictions

This improper style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

22.9.5 Related commands

improper_coeff

Default: none

22.10 improper_style distharm command

22.10.1 Syntax

```improper_style distharm```

22.10.2 Examples

```improper_style distharm
improper_coeff 1 25.0 0.5```

22.10.3 Description

The `distharm` improper style uses the potential

\[ E = K(d - d_0)^2 \]

where \(d\) is the oriented distance between the central atom and the plane formed by the other three atoms. If the 4 atoms in an improper quadruplet (listed in the data file read by the `read_data` command) are ordered I,J,K,L then the L-atom is assumed to be the central atom. Note that this is different from the convention used in the improper_style distance. The distance \(d\) is oriented and can take on negative values. This may lead to unwanted behavior if \(d_0\) is not equal to zero.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \(K\) (energy/distance^2)
- \(d_0\) (distance)
22.10.4 Restrictions

This improper style can only be used if LAMMPS was built with the USER-YAFF package. See the Build package doc page for more info.

22.10.5 Related commands

\textit{improper_coeff}

\textbf{Default:} none

22.11 improper\_style fourier command

22.12 improper\_style fourier/omp command

22.12.1 Syntax

```
improper_style fourier
```

22.12.2 Examples

```
improper_style fourier
improper_coeff 1 100.0 0.0 1.0 0.5 1
```

22.12.3 Description

The \textit{fourier} improper style uses the following potential:

\[ E = K[C_0 + C_1 \cos(\omega) + C_2 \cos(2\omega)] \]

where \( K \) is the force constant, \( C_0, C_1, C_2 \) are dimensionless coefficients, and \( \omega \) is the angle between the IL axis and the IJK plane:
If all parameter (see below) is not zero, the all the three possible angles will taken in account.

The following coefficients must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $K$ (energy)
- $C_0$ (unitless)
- $C_1$ (unitless)
- $C_2$ (unitless)
- all (0 or 1, optional)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
22.12.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER_MISC package. See the Build package doc page for more info.

22.12.5 Related commands

improper_coeff

Default: none

22.13 improper_style harmonic command

22.14 improper_style harmonic/intel command

22.15 improper_style harmonic/kk command

22.16 improper_style harmonic/omp command

22.16.1 Syntax

improper_style harmonic

22.16.2 Examples

improper_style harmonic
improper_coeff 1 100.0 0

22.16.3 Description

The harmonic improper style uses the potential

\[ E = K(\chi - \chi_0)^2 \]

where \( \chi \) is the improper angle, \( \chi_0 \) is its equilibrium value, and \( K \) is a prefactor. Note that the usual 1/2 factor is included in \( K \).

If the 4 atoms in an improper quadruplet (listed in the data file read by the read_data command) are ordered I,J,K,L then \( \chi \) is the angle between the plane of I,J,K and the plane of J,K,L. Alternatively, you can think of atoms J,K,L as being in a plane, and atom I above the plane, and \( \chi \) as a measure of how far out-of-plane I is with respect to the other 3 atoms.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:
• $K$ (energy/radian²)
• $\chi_0$ (degrees)

$\chi_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence the units of $K$ are in energy/radian².

Styles with a $gpu$, $intel$, $kk$, $omp$, or $opt$ suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 22.16.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

### 22.16.5 Related commands

**improper_coeff**

Default: none

### 22.17 improper_style hybrid command

#### 22.17.1 Syntax

```plaintext
improper_style hybrid style1 style2 ...
```

- style1,style2 = list of one or more improper styles

#### 22.17.2 Examples

```plaintext
improper_style hybrid harmonic helix
improper_coeff 1 harmonic 120.0 30
improper_coeff 2 cvff 20.0 -1 2
```
22.17.3 Description

The hybrid style enables the use of multiple improper styles in one simulation. An improper style is assigned to each improper type. For example, impropers in a polymer flow (of improper type 1) could be computed with a harmonic potential and impropers in the wall boundary (of improper type 2) could be computed with a cvff potential. The assignment of improper type to style is made via the improper_coeff command or in the data file.

In the improper_coeff command, the first coefficient sets the improper style and the remaining coefficients are those appropriate to that style. In the example above, the 2 improper_coeff commands would set impropers of improper type 1 to be computed with a harmonic potential with coefficients 120.0, 30 for $K$, $\chi_0$. Improper type 2 would be computed with a cvff potential with coefficients 20.0, -1, 2 for $K$, $d$, and $n$, respectively.

If the improper class2 potential is one of the hybrid styles, it requires additional AngleAngle coefficients be specified in the data file. These lines must also have an additional “class2” argument added after the improper type. For improper types which are assigned to other hybrid styles, use the style name (e.g. “harmonic”) appropriate to that style. The AngleAngle coeffs for that improper type will then be ignored.

An improper style of none can be specified as the second argument to the improper_coeff command, if you desire to turn off certain improper types.

22.17.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

Unlike other improper styles, the hybrid improper style does not store improper coefficient info for individual sub-styles in a binary restart files. Thus when restarting a simulation from a restart file, you need to re-specify improper_coeff commands.

22.17.5 Related commands

improper_coeff

Default: none

22.18 improper_style inversion/harmonic command

22.18.1 Syntax

improper_style inversion/harmonic
22.18.2 Examples

```plaintext
improper_style inversion/harmonic
improper_coeff 1 18.776340 0.000000
```

22.18.3 Description

The *inversion/harmonic* improper style follows the Wilson-Decius out-of-plane angle definition and uses an harmonic potential:

\[ E = K (\omega - \omega_0)^2 \]

where \( K \) is the force constant and \( \omega \) is the angle evaluated for all three axis-plane combinations centered around the atom I. For the IL axis and the IJK plane \( \omega \) looks as follows:

Note that the *inversion/harmonic* angle term evaluation differs to the *improper_umbrella* due to the cyclic evaluation of all possible angles \( \omega \).

The following coefficients must be defined for each improper type via the *improper_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( K \) (energy)
- \( \omega_0 \) (degrees)

If \( \omega_0 = 0 \) the potential term has a single minimum for the planar structure. Otherwise it has two minima at \( \pm \omega_0 \), with a barrier in between.
22.18.4 Restrictions

This improper style can only be used if LAMMPS was built with the USER-MOFFF package. See the Build package doc page for more info.

22.18.5 Related commands

improper_coeff

Default: none

22.19 improper_style none command

22.19.1 Syntax

improper_style none

22.19.2 Examples

improper_style none

22.19.3 Description

Using an improper style of none means improper forces and energies are not computed, even if quadruplets of improper atoms were listed in the data file read by the read_data command.

See the improper_style zero command for a way to calculate improper statistics, but compute no improper interactions.

22.19.4 Restrictions

none

22.19.5 Related commands

improper_style zero

Default: none
22.20 improper_style ring command

22.21 improper_style ring/omp command

22.21.1 Syntax

```
improper_style ring
```

22.21.2 Examples

```
improper_style ring
improper_coeff 1 8000 70.5
```

22.21.3 Description

The `ring` improper style uses the potential

\[ E = \frac{1}{6} K (\Delta_{ijl} + \Delta_{ijk} + \Delta_{kjl})^6 \]

\[ \Delta_{ijl} = \cos \theta_{ijl} - \cos \theta_0 \]

\[ \Delta_{ijk} = \cos \theta_{ijk} - \cos \theta_0 \]

\[ \Delta_{kjl} = \cos \theta_{kjl} - \cos \theta_0 \]

where \( K \) is a prefactor, \( \theta \) is the angle formed by the atoms specified by \((i,j,k,l)\) indices and \( \theta_0 \) its equilibrium value.

If the 4 atoms in an improper quadruplet (listed in the data file read by the `read_data` command) are ordered \(i,j,k,l\) then \( \theta_{ijl} \) is the angle between atoms \(i,j\) and \(l\), \( \theta_{ijk} \) is the angle between atoms \(i,j\) and \(k\), \( \theta_{kjl} \) is the angle between atoms \(j,k\), and \(l\).

The “ring” improper style implements the improper potential introduced by Destree et al., in Equation (9) of (Destree). This potential does not affect small amplitude vibrations but is used in an ad-hoc way to prevent the onset of accidentally large amplitude fluctuations leading to the occurrence of a planar conformation of the three bonds \(i-j, j-k\) and \(j-l\), an intermediate conformation toward the chiral inversion of a methine carbon. In the “Impropers” section of data file four atoms: \(i, j, k\) and \(l\) are specified with \(i,j\) and \(l\) lying on the backbone of the chain and \(k\) specifying the chirality of \(j\).

The following coefficients must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy)
- \( \theta_0 \) (degrees)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix 
command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

### 22.21.4 Restrictions

This improper style can only be used if LAMMPS was built with the USER-MISC package. See the *Build package* doc page for more info.

22.23 improper_style umbrella command

22.24 improper_style umbrella/omp command

22.24.1 Syntax

\texttt{improper_style umbrella}

22.24.2 Examples

\begin{verbatim}
improper_style umbrella
improper_coeff 1 100.0 180.0
\end{verbatim}

22.24.3 Description

The \textit{umbrella} improper style uses the following potential, which is commonly referred to as a classic inversion and used in the \textit{DREIDING} force field:

\begin{align*}
E &= \frac{1}{2} K \left( \frac{1}{\sin \omega_0} \right)^2 (\cos \omega - \cos \omega_0)^2 \quad \omega_0 \neq 0^\circ \\
E &= K (1 - \cos \omega) \quad \omega_0 = 0^\circ
\end{align*}

where $K$ is the force constant and $\omega$ is the angle between the IL axis and the IJK plane:
If $\omega_0 = 0$ the potential term has a minimum for the planar structure. Otherwise it has two minima at $\omega + / - \omega_0$, with a barrier in between.

See (Mayo) for a description of the DREIDING force field.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- $K$ (energy)
- $\omega_0$ (degrees)

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

**22.24.4 Restrictions**

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

22.25.1 Syntax

improper_style zero [ncoeff]

22.25.2 Examples

improper_style zero
improper_style zero ncoeff
improper_coeff *

22.25.3 Description

Using an improper style of zero means improper forces and energies are not computed, but the geometry of improper quadruplets is still accessible to other commands.

As an example, the *compute improper/local* command can be used to compute the chi values for the list of quadruplets of improper atoms listed in the data file read by the *read_data* command. If no improper style is defined, this command cannot be used.

The optional *ncoeff* flag allows to read data files with an ImproperCoeff section for any improper style. Similarly, any improper_coeff commands will only be checked for the improper type number and the rest ignored.

Note that the *improper_coeff* command must be used for all improper types, though no additional values are specified.
