19.45 compute hexorder/atom command

19.45.1 Syntax

```
compute ID group-ID hexorder/atom keyword values ...
```

- ID, group-ID are documented in `compute` command
- hexorder/atom = style name of this compute command
- one or more keyword/value pairs may be appended
  ```
  keyword = degree or nnn or cutoff
  cutoff value = distance cutoff
  nnn value = number of nearest neighbors
  degree value = degree n of order parameter
  ```

19.45.2 Examples

```
compute 1 all hexorder/atom
compute 1 all hexorder/atom degree 4 nnn 4 cutoff 1.2
```
19.45.3 Description

Define a computation that calculates $q_n$, the bond-orientational order parameter for each atom in a group. The hexatic ($n = 6$) order parameter was introduced by Nelson and Halperin as a way to detect hexagonal symmetry in two-dimensional systems. For each atom, $q_n$ is a complex number (stored as two real numbers) defined as follows:

$$q_n = \frac{1}{nnn} \sum_{j=1}^{nnn} e^{in\theta(r_{ij})}$$

where the sum is over the $nnn$ nearest neighbors of the central atom. The angle $\theta$ is formed by the bond vector $r_{ij}$ and the $x$ axis. $\theta$ is calculated only using the $x$ and $y$ components, whereas the distance from the central atom is calculated using all three $x$, $y$, and $z$ components of the bond vector. Neighbor atoms not in the group are included in the order parameter of atoms in the group.

The optional keyword `cutoff` defines the distance cutoff used when searching for neighbors. The default value, also the maximum allowable value, is the cutoff specified by the pair style.

The optional keyword `nnn` defines the number of nearest neighbors used to calculate $q_n$. The default value is 6. If the value is NULL, then all neighbors up to the distance cutoff are used.

The optional keyword `degree` sets the degree $n$ of the order parameter. The default value is 6. For a perfect hexagonal lattice with $nnn = 6$, $q_6 = e^{6i\phi}$ for all atoms, where the constant $0 < \phi < \frac{\pi}{3}$ depends only on the orientation of the lattice relative to the $x$ axis. In an isotropic liquid, local neighborhoods may still exhibit weak hexagonal symmetry, but because the orientational correlation decays quickly with distance, the value of $\phi$ will be different for different atoms, and so when $q_6$ is averaged over all the atoms in the system, $|\langle q_6 \rangle| << 1$.

The value of $q_n$ is set to zero for atoms not in the specified compute group, as well as for atoms that have less than $nnn$ neighbors within the distance cutoff.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

**Note:** If you have a bonded system, then the settings of `special_bonds` command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the `special_bonds` command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the order parameter. This difficulty can be circumvented by writing a dump file, and using the `rerun` command to compute the order parameter for snapshots in the dump file. The rerun script can use a `special_bonds` command that includes all pairs in the neighbor list.

19.45.4 Output info

This compute calculates a per-atom array with 2 columns, giving the real and imaginary parts $q_n$, a complex number restricted to the unit disk of the complex plane i.e. $Re(q_n)^2 + Im(q_n)^2 <= 1$.

These values can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

\end{align*}
\]
19.46.3 Description

Define a computation that calculates the properties of a solid (potential energy, pressure or heat capacity), using the harmonically-mapped averaging (HMA) method. This command yields much higher precision than the equivalent compute commands (compute pe, compute pressure, etc.) commands during a canonical simulation of an atomic crystal. Specifically, near melting HMA can yield averages of a given precision an order of magnitude faster than conventional methods, and this only improves as the temperatures is lowered. This is particularly important for evaluating the free energy by thermodynamic integration, where the low-temperature contributions are the greatest source of statistical uncertainty. Moreover, HMA has other advantages, including smaller potential-truncation effects, finite-size effects, smaller timestep inaccuracy, faster equilibration and shorter decorrelation time.

HMA should not be used if atoms are expected to diffuse. It is also restricted to simulations in the NVT ensemble. While this compute may be used with any potential in LAMMPS, it will provide inaccurate results for potentials that do not go to 0 at the truncation distance; pair_style lj/smooth/linear and Ewald summation should work fine, while pair_style lj/cut will perform poorly unless the potential is shifted (via pair_modify shift) or the cutoff is large. Furthermore, computation of the heat capacity with this compute is restricted to those that implement the single_hessian method in Pair. Implementing single_hessian in additional pair styles is simple. Please contact Andrew Schultz (ajs42 at buffalo.edu) and David Kofke (kofke at buffalo.edu) if your desired pair style does not have this method. This is the list of pair styles that currently implement single_hessian:

- pair_style lj/smooth/linear

In this method, the analytically known harmonic behavior of a crystal is removed from the traditional ensemble averages, which leads to an accurate and precise measurement of the anharmonic contributions without contamination by noise produced by the already-known harmonic behavior. A detailed description of this method can be found in (Moustafa). The potential energy is computed by the formula:

$$\langle U \rangle_{HMA} = \frac{d}{2}(N-1)k_B T + \left\langle U + \frac{1}{2}F \cdot \Delta r \right\rangle$$

where \(N\) is the number of atoms in the system, \(k_B\) is Boltzmann’s constant, \(T\) is the temperature, \(d\) is the dimensionality of the system (2 or 3 for 2d/3d), \(F \cdot \Delta r\) is the sum of dot products of the atomic force vectors and displacement (from lattice sites) vectors, and \(U\) is the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix energies.

The pressure is computed by the formula:

$$\langle P \rangle_{HMA} = \Delta \hat{P} + \left\langle P_{vir} + \frac{\beta \Delta \hat{P} - \rho}{d(N-1)} F \cdot \Delta r \right\rangle$$

where \(\rho\) is the number density of the system, \(\Delta \hat{P}\) is the difference between the harmonic and lattice pressure, \(P_{vir}\) is the virial pressure computed as the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix contributions to the force on each atom, and \(k_B = 1/k_B T\). Although the method will work for any value of \(\Delta \hat{P}\) specified (use pressure units), the precision of the resultant pressure is sensitive to \(\Delta \hat{P}\); the precision tends to be best when \(\Delta \hat{P}\) is the actual the difference between the lattice pressure and harmonic pressure.

$$\langle C_V \rangle_{HMA} = \frac{d}{2}(N-1)k_B + \frac{1}{k_B T^2} \left( \langle U_{HMA}^2 \rangle - \langle U_{HMA} \rangle^2 \right) + \frac{1}{4T} \left\langle F \cdot \Delta r + \Delta r \cdot \Phi \cdot \Delta r \right\rangle$$

where \(\Phi\) is the Hessian matrix. The compute hma command computes the full expression for \(C_V\) except for the \(\langle U_{HMA}^2 \rangle^2\) in the variance term, which can be obtained by passing the \(u\) keyword; you must add this extra contribution to the \(C_V\) value reported by this compute. The variance term can cause significant round-off error when computing \(C_V\). To address this, the anharmonic keyword can be passed and/or the output format can be specified with more digits.

thermo_modify format float '%22.15e'
The \textit{anharmonic} keyword will instruct the compute to return anharmonic properties rather than the full properties, which include lattice, harmonic and anharmonic contributions. When using this keyword, the compute must be first active (it must be included via a \textit{thermo\_style\_custom} command) while the atoms are still at their lattice sites (before equilibration).

The temp-ID specified with compute hma command should be same as the fix-ID of Nose-Hoover (\textit{fix nvt}) or Berendsen (\textit{fix temp/berendsen}) thermostat used for the simulation. While using this command, Langevin thermostat (\textit{fix langevin}) should be avoided as its extra forces interfere with the HMA implementation.

\textbf{Note:} Compute hma command should be used right after the energy minimization, when the atoms are at their lattice sites. The simulation should not be started before this command has been used in the input script.

The following example illustrates the placement of this command in the input script:

\begin{verbatim}
min_style cg
minimize 1e-35 1e-15 50000 500000
compute 1 all hma thermostatid u
fix thermostatid all nvt temp 600.0 600.0 100.0
\end{verbatim}

\textbf{Note:} Compute hma should be used when the atoms of the solid do not diffuse. Diffusion will reduce the precision in the potential energy computation.

\textbf{Note:} The \textit{fix\_modify\_energy\_yes} command must also be specified if a fix is to contribute potential energy to this command.

An example input script that uses this compute is included in examples/USER/hma/ along with corresponding LAMMPS output showing that the HMA properties fluctuate less than the corresponding conventional properties.

\section{19.46.4 Output info}

This compute calculates a global vector that includes the n properties requested as arguments to the command (the potential energy, pressure and/or heat capacity). The elements of the vector can be accessed by indices 1-n by any command that uses global vector values as input. See the \textit{Howto output} doc page for an overview of LAMMPS output options.

The vector values calculated by this compute are “extensive”. The scalar value will be in energy \textit{units}.

\section{19.46.5 Restrictions}

This compute is part of the USER-MISC package. It is enabled only if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

Usage restricted to canonical (NVT) ensemble simulation only.

19.47 compute improper command

19.47.1 Syntax

```
compute ID group-ID improper
```

- ID, group-ID are documented in *compute* command
- improper = style name of this compute command

19.47.2 Examples

```
compute 1 all improper
```

19.47.3 Description

Define a computation that extracts the improper energy calculated by each of the improper sub-styles used in the *improper_style hybrid* command. These values are made accessible for output or further processing by other commands. The group specified for this command is ignored.

This compute is useful when using *improper_style hybrid* if you want to know the portion of the total energy contributed by one or more of the hybrid sub-styles.

19.47.4 Output info

This compute calculates a global vector of length N where N is the number of sub_styles defined by the *improper_style hybrid* command, which can be accessed by indices 1-N. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The vector values are “extensive” and will be in energy units.

19.48 compute improper/local command

19.48.1 Syntax

```
compute ID group-ID improper/local value1 value2 ...
```

- ID, group-ID are documented in *compute* command
- improper/local = style name of this compute command
- one or more values may be appended
  - value = chi
    - chi = tabulate improper angles

19.48.2 Examples

```
compute 1 all improper/local chi
```

19.48.3 Description

Define a computation that calculates properties of individual improper interactions. The number of datums generated, aggregated across all processors, equals the number of impropers in the system, modified by the group parameter as explained below.

The value *chi* is the improper angle, as defined in the doc pages for the individual improper styles listed on *improper_style* doc page.

The local data stored by this command is generated by looping over all the atoms owned on a processor and their impropers. An improper will only be included if all 4 atoms in the improper are in the specified compute group.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, improper output from the *compute property/local* command can be combined with data from this command and output by the *dump local* command in a consistent way.

Here is an example of how to do this:
19.48.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of impropers. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The output for chi will be in degrees.

19.49 compute inertia/chunk command

19.49.1 Syntax

\texttt{compute ID group-ID inertia/chunk chunkID}

- ID, group-ID are documented in \texttt{compute} command
- inertia/chunk = style name of this compute command
- chunkID = ID of \texttt{compute chunk/atom} command

19.49.2 Examples

\texttt{compute 1 fluid inertia/chunk molchunk}
19.49.3 Description

Define a computation that calculates the inertia tensor for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and Howto chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the 6 components of the symmetric inertia tensor for each chunk, ordered Ixx, Iyy, Izz, Ixy, Iyz, Ixz. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The compute chunk/atom command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

Note: The coordinates of an atom contribute to the chunk’s inertia tensor in “unwrapped” form, by using the image flags associated with each atom. See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the set image command.

The simplest way to output the results of the compute inertia/chunk calculation to a file is to use the fix ave/time command, for example:

```
compute ccl all chunk/atom molecule
compute myChunk all inertia/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

19.49.4 Output info

This compute calculates a global array where the number of rows = the number of chunks Nchunk as calculated by the specified compute chunk/atom command. The number of columns = 6 for the 6 components of the inertia tensor for each chunk, ordered as listed above. These values can be accessed by any command that uses global array values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in mass*distance^2 units.

19.50.1 Syntax

\texttt{compute ID group-ID ke}

- ID, group-ID are documented in \textit{compute} command
- \textit{ke} = style name of this compute command

19.50.2 Examples

\texttt{compute 1 all ke}

19.50.3 Description

Define a computation that calculates the translational kinetic energy of a group of particles. The kinetic energy of each particle is computed as $\frac{1}{2}mv^2$, where $m$ and $v$ are the mass and velocity of the particle.

There is a subtle difference between the quantity calculated by this compute and the kinetic energy calculated by the \textit{ke} or \textit{etotal} keyword used in thermodynamic output, as specified by the \textit{thermo_style} command. For this compute, kinetic energy is “translational” kinetic energy, calculated by the simple formula above. For thermodynamic output, the \textit{ke} keyword infers kinetic energy from the temperature of the system with $\frac{1}{2}k_BT$ of energy for each degree of freedom. For the default temperature computation via the \textit{compute temp} command, these are the same. But different computes that calculate temperature can subtract out different non-thermal components of velocity and/or include different degrees of freedom (translational, rotational, etc).

19.50.4 Output info

This compute calculates a global scalar (the summed KE). This value can be used by any command that uses a global scalar value from a compute as input. See the \textit{Howto output} doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy \textit{units}.

19.52.1 Syntax

\[
\text{compute ID group-ID ke/atom/eff}
\]

- ID, group-ID are documented in `compute` command
- `ke/atom/eff` = style name of this compute command

19.52.2 Examples

```
compute 1 all ke/atom/eff
```

19.52.3 Description

Define a computation that calculates the per-atom translational (nuclei and electrons) and radial kinetic energy (electron only) in a group. The particles are assumed to be nuclei and electrons modeled with the electronic force field.

The kinetic energy for each nucleus is computed as \( \frac{1}{2}mv^2 \), where \( m \) corresponds to the corresponding nuclear mass, and the kinetic energy for each electron is computed as \( \frac{1}{2}(m_e v^2 + \frac{3}{4}m_e s^2) \), where \( m_e \) and \( v \) correspond to the mass and translational velocity of each electron, and \( s \) to its radial velocity, respectively.

There is a subtle difference between the quantity calculated by this compute and the kinetic energy calculated by the `ke` or `etotal` keyword used in thermodynamic output, as specified by the `thermo_style` command. For this compute, kinetic energy is “translational” plus electronic “radial” kinetic energy, calculated by the simple formula above. For thermodynamic output, the `ke` keyword infers kinetic energy from the temperature of the system with \( \frac{1}{2}k_B T \) of energy for each (nuclear-only) degree of freedom in eFF.

**Note:** The temperature in eFF should be monitored via the `compute temp/eff` command, which can be printed with thermodynamic output by using the `thermo_modify` command, as shown in the following example:

```
compute effTemp all temp/eff
thermo_style custom step etotal pe ke temp press
thermo_modify temp effTemp
```

The value of the kinetic energy will be 0.0 for atoms (nuclei or electrons) not in the specified compute group.
19.52.4 Output info

This compute calculates a scalar quantity for each atom, which can be accessed by any command that uses per-atom computes as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector values will be in energy units.

19.52.5 Restrictions

This compute is part of the USER-EFF package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

- `fix-ID = ID of rigid body fix`

19.54. compute ke/rigid command 1551
19.54.2 Examples

```compute l all ke/rigid myRigid```

19.54.3 Description

Define a computation that calculates the translational kinetic energy of a collection of rigid bodies, as defined by one of the `fix rigid` command variants.

The kinetic energy of each rigid body is computed as $1/2 M V_{cm}^2$, where $M$ is the total mass of the rigid body, and $V_{cm}$ is its center-of-mass velocity.

The `fix-ID` should be the ID of one of the `fix rigid` commands which defines the rigid bodies. The group specified in the compute command is ignored. The kinetic energy of all the rigid bodies defined by the fix rigid command in included in the calculation.

19.54.4 Output info

This compute calculates a global scalar (the summed KE of all the rigid bodies). This value can be used by any command that uses a global scalar value from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy units.

19.54.5 Restrictions

This compute is part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

19.55 compute mesont command

19.55.1 Syntax

```compute ID group-ID mesont mode```

- ID, group-ID are documented in `compute` command
- mesont = style name of the compute command
- mode = one of estretch, ebend, etube (see details below)
19.55.2 Examples

```
compute 1 all mesont estretch
```

19.55.3 Description

These computes define computations for the stretching (estretch), bending (ebend), and intertube (etube) per-node (atom) and total energies. The evaluated value is selected by a parameter passed to the compute: estretch, ebend, etube.

19.55.4 Output info

These computes calculate per-node (per-atom) vectors, which can be accessed by any command that uses per-atom values from a compute as input, and global scalars. See the *Howto output* doc page for an overview of LAMMPS output options.

The computed values are provided in energy *units*.

19.55.5 Restrictions

These computes are part of the USER-MESONT package. They are only enabled if LAMMPS is built with that package. See the *Build package* doc page for more info. In addition, *mesont pair_style* must be used.

  style = linear or quadratic
  descriptor values = style filename
  style = sna
  ```
filename = name of file containing descriptor definitions
gradgradflag value = 0/1
toggle gradgrad method for force gradient

19.56.2 Examples

compute mliap model linear descriptor sna Ta06A.mliap.descriptor

19.56.3 Description

Compute style mliap provides a general interface to the gradient of machine-learning interatomic potentials w.r.t. model parameters. It is used primarily for calculating the gradient of energy, force, and stress components w.r.t. model parameters, which is useful when training mliap pair_style models to match target data. It provides separate definitions of the interatomic potential functional form (model) and the geometric quantities that characterize the atomic positions (descriptor). By defining model and descriptor separately, it is possible to use many different models with a given descriptor, or many different descriptors with a given model. Currently, the compute supports just two models, linear and quadratic, and one descriptor, sna, the SNAP descriptor used by pair_style snap, including the linear, quadratic, and chem variants. Work is currently underway to extend the interface to handle neural network energy models, and it is also straightforward to add new descriptor styles.

The compute mliap command must be followed by two keywords model and descriptor in either order. The model keyword is followed by a model style, currently limited to either linear or quadratic.

The descriptor keyword is followed by a descriptor style, and additional arguments. Currently the only descriptor style is sna, indicating the bispectrum component descriptors used by the Spectral Neighbor Analysis Potential (SNAP) potentials of pair_style snap. A single additional argument specifies the descriptor filename containing the parameters and setting used by the SNAP descriptor. The descriptor filename usually ends in the .mliap.descriptor extension. The format of this file is identical to the descriptor file in the pair_style mliap, and is described in detail there.

Note: The number of LAMMPS atom types (and the value of nelems in the model) must match the value of nelems in the descriptor file.

Compute mliap calculates a global array containing gradient information. The number of columns in the array is nelems x nparams + 1. The first row of the array contain the derivative of potential energy w.r.t. to each parameter and each element. The last six rows of the array contain the corresponding derivatives of the virial stress tensor, listed in Voigt notation: pxx, pyy, pzz, pyz, pxz, pxy. In between the energy and stress rows are the 3*N rows containing the derivatives of the force components. See section below on output for a detailed description of how rows and columns are ordered.

The element in the last column of each row contains the potential energy, force, or stress, according to the row. These quantities correspond to the user-specified reference potential that must be subtracted from the target data when training a model. The potential energy calculation uses the built in compute thermo_pe. The stress calculation uses a compute called mliap_press that is automatically created behind the scenes, according to the following command:

compute mliap_press all pressure NULL virial

See section below on output for a detailed explanation of the data layout in the global array.

The optional keyword gradgradflag controls how the force gradient is calculated. A value of 1 requires that the model provide the matrix of double gradients of energy w.r.t. both parameters and descriptors. For the linear and quadratic models this matrix is sparse and so is easily calculated and stored. For other models, this matrix may be prohibitively expensive to calculate and store. A value of 0 requires that the descriptor provide the derivative of the descriptors w.r.t.
the position of every neighbor atom. This is not optimal for linear and quadratic models, but may be a better choice
for more complex models.

Atoms not in the group do not contribute to this compute. Neighbor atoms not in the group do not contribute to this
compute. The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e.
each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

**Note:** If the user-specified reference potentials includes bonded and non-bonded pairwise interactions, then the
settings of `special_bonds` command can remove pairwise interactions between atoms in the same bond, angle, or
dihedral. This is the default setting for the `special_bonds` command, and means those pairwise interactions do not
appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in
the calculation. The `rerun` command is not an option here, since the reference potential is required for the last column
of the global array. A work-around is to prevent pairwise interactions from being removed by explicitly adding a tiny
positive value for every pairwise interaction that would otherwise be set to zero in the `special_bonds` command.

### 19.56.4 Output info

Compute `mliap` evaluates a global array. The columns are arranged into `nelems` blocks, listed in order of element $I$.
Each block contains one column for each of the `nparams` model parameters. A final column contains the corresponding
energy, force component on an atom, or virial stress component. The rows of the array appear in the following order:

- 1 row: Derivatives of potential energy w.r.t. each parameter of each element.
- 3*$N$ rows: Derivatives of force components. x, y, and z components of force on atom $i$ appearing in consecutive
  rows. The atoms are sorted based on atom ID.
- 6 rows: Derivatives of virial stress tensor w.r.t. each parameter of each element. The ordering of the rows
  follows Voigt notation: $p_{xx}$, $p_{yy}$, $p_{zz}$, $p_{yz}$, $p_{xz}$, $p_{xy}$.

These values can be accessed by any command that uses a global array from a compute as input. See the `Howto
output` doc page for an overview of LAMMPS output options. To see how this command can be used within a Python
workflow to train machine-learning interatomic potentials, see the examples in `FitSNAP`.

### 19.56.5 Restrictions

This compute is part of the MLIAP package. It is only enabled if LAMMPS was built with that package. In addition,
building LAMMPS with the MLIAP package requires building LAMMPS with the SNAP package. See the `Build
package` doc page for more info.

19.58 compute msd command

19.58.1 Syntax

```
compute ID group-ID msd keyword values ...
```

- ID, group-ID are documented in `compute` command
- msd = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = `com` or `average`

```
com value = yes or no
average value = yes or no
```

19.58.2 Examples

```
compute 1 all msd
compute 1 upper msd com yes average yes
```

19.58.3 Description

Define a computation that calculates the mean-squared displacement (MSD) of the group of atoms, including all effects due to atoms passing through periodic boundaries. For computation of the non-Gaussian parameter of mean-squared displacement, see the `compute msd/nongauss` command.

A vector of four quantities is calculated by this compute. The first 3 elements of the vector are the squared dx,dy,dz displacements, summed and averaged over atoms in the group. The fourth element is the total squared displacement, i.e. \( (dx^2 + dy^2 + dz^2) \), summed and averaged over atoms in the group.

The slope of the mean-squared displacement (MSD) versus time is proportional to the diffusion coefficient of the diffusing atoms.

The displacement of an atom is from its reference position. This is normally the original position at the time the compute command was issued, unless the `average` keyword is set to `yes`. The value of the displacement will be 0.0 for atoms not in the specified compute group.

If the `com` option is set to `yes` then the effect of any drift in the center-of-mass of the group of atoms is subtracted out before the displacement of each atom is calculated.

If the `average` option is set to `yes` then the reference position of an atom is based on the average position of that atom, corrected for center-of-mass motion if requested. The average position is a running average over all previous calls to the compute, including the current call. So on the first call it is current position, on the second call it is the arithmetic average of the current position and the position on the first call, and so on. Note that when using this option, the precise value of the mean square displacement will depend on the number of times the compute is called. So, for example, changing the frequency of thermo output may change the computed displacement. Also, the precise values will be changed if a single simulation is broken up into two parts, using either multiple run commands or a restart file. It only makes sense to use this option if the atoms are not diffusing, so that their average positions relative to the center of mass of the system are stationary. The most common case is crystalline solids undergoing thermal motion.

Note: Initial coordinates are stored in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data`
command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the set image command.

**Note:** If you want the quantities calculated by this compute to be continuous when running from a restart file, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with atom reference positions from the restart file. When average is set to yes, then the atom reference positions are restored correctly, but not the number of samples used obtain them. As a result, the reference positions from the restart file are combined with subsequent positions as if they were from a single sample, instead of many, which will change the values of msd somewhat.

### 19.58.4 Output info

This compute calculates a global vector of length 4, which can be accessed by indices 1–4 by any command that uses global vector values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The vector values will be in distance^2 units.

### 19.59 compute msd/chunk command

#### 19.59.1 Syntax

```plaintext
compute ID group-ID msd/chunk chunkID
```

- ID, group-ID are documented in *compute* command
- msd/chunk = style name of this compute command
- chunkID = ID of *compute chunk/atom* command
19.59.2 Examples

\texttt{compute 1 all msd/chunk molchunk}

19.59.3 Description

Define a computation that calculates the mean-squared displacement (MSD) for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a \texttt{compute chunk/atom} command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the \texttt{compute chunk/atom} and \textit{Howto chunk} doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

Four quantities are calculated by this compute for each chunk. The first 3 quantities are the squared $dx,dy,dz$ displacements of the center-of-mass. The fourth component is the total squared displacement, i.e. $(dx^2 + dy^2 + dz^2)$ of the center-of-mass. These calculations include all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The \texttt{compute chunk/atom} command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

The slope of the mean-squared displacement (MSD) versus time is proportional to the diffusion coefficient of the diffusing chunks.

The displacement of the center-of-mass of the chunk is from its original center-of-mass position, calculated on the timestep this compute command was first invoked.

\textbf{Note:} The number of chunks $N_{\text{chunk}}$ calculated by the \texttt{compute chunk/atom} command must remain constant each time this compute is invoked, so that the displacement for each chunk from its original position can be computed consistently. If $N_{\text{chunk}}$ does not remain constant, an error will be generated. If needed, you can enforce a constant $N_{\text{chunk}}$ by using the \texttt{nchunk once} or \texttt{ids once} options when specifying the \texttt{compute chunk/atom} command.

\textbf{Note:} This compute stores the original position (of the center-of-mass) of each chunk. When a displacement is calculated on a later timestep, it is assumed that the same atoms are assigned to the same chunk ID. However LAMMPS has no simple way to insure this is the case, though you can use the \texttt{ids once} option when specifying the \texttt{compute chunk/atom} command. Note that if this is not the case, the MSD calculation does not have a sensible meaning.

\textbf{Note:} The initial coordinates of the atoms in each chunk are stored in “unwrapped” form, by using the image flags associated with each atom. See the \texttt{dump custom} command for a discussion of “unwrapped” coordinates. See the Atoms section of the \texttt{read_data} command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the \texttt{set image} command.

\textbf{Note:} If you want the quantities calculated by this compute to be continuous when running from a \texttt{restart file}, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-chunk quantities will also have the same ID, and thus be initialized correctly with chunk reference positions from the restart file.
The simplest way to output the results of the compute msd/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute c1 all chunk/atom molecule
compute myChunk all msd/chunk c1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 19.59.4 Output info

This compute calculates a global array where the number of rows = the number of chunks $N_{chunk}$ as calculated by the specified `compute chunk/atom` command. The number of columns = 4 for $dx,dy,dz$ and the total displacement. These values can be accessed by any command that uses global array values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in distance^2 units.

### 19.60 compute msd/nongauss command

#### 19.60.1 Syntax

```
compute ID group-ID msd/nongauss keyword values ...
```

- ID, group-ID are documented in `compute` command
- `msd/nongauss` = style name of this compute command
- zero or more keyword/value pairs may be appended
- `keyword = com`
  
  `com value = yes or no`
19.60.2 Examples

```
compute 1 all msd/nongauss
compute 1 upper msd/nongauss com yes
```

19.60.3 Description

Define a computation that calculates the mean-squared displacement (MSD) and non-Gaussian parameter (NGP) of the group of atoms, including all effects due to atoms passing through periodic boundaries.

A vector of three quantities is calculated by this compute. The first element of the vector is the total squared dx,dy,dz displacements $dr_{squared} = (dx^2 + dy^2 + dz^2)$ of atoms, and the second is the fourth power of these displacements $dr_{fourth} = (dx^2 + dy^2 + dz^2)^2 (dx^2 + dy^2 + dz^2)$, summed and averaged over atoms in the group. The third component is the non-Gaussian diffusion parameter $NGP = 3*dr_{fourth}/(5*dr_{squared}^2)$, i.e.

$$NGP(t) = 3 <(r(t) - r(0))^4>/5 <(r(t) - r(0))^2>^2 - 1$$

The NGP is a commonly used quantity in studies of dynamical heterogeneity. Its minimum theoretical value (-0.4) occurs when all atoms have the same displacement magnitude. NGP=0 for Brownian diffusion, while NGP > 0 when some mobile atoms move faster than others.

If the `com` option is set to `yes` then the effect of any drift in the center-of-mass of the group of atoms is subtracted out before the displacement of each atom is calculated.

See the `compute msd` doc page for further important NOTEs, which also apply to this compute.

19.60.4 Output info

This compute calculates a global vector of length 3, which can be accessed by indices 1-3 by any command that uses global vector values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The first vector value will be in distance^2 units, the second is in distance^4 units, and the third is dimensionless.

19.60.5 Restrictions

This compute is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

19.60.6 Related commands

`compute msd`
19.60.7 Default

The option default is com = no.

19.61 compute omega/chunk command

19.61.1 Syntax

```
compute ID group-ID omega/chunk chunkID
```

- ID, group-ID are documented in compute command
- omega/chunk = style name of this compute command
- chunkID = ID of compute chunk/atom command

19.61.2 Examples

```
compute 1 fluid omega/chunk molchunk
```

19.61.3 Description

Define a computation that calculates the angular velocity (omega) of multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and Howto chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the 3 components of the angular velocity vector for each chunk, via the formula \( \mathbf{L} = \mathbf{I}\omega \) where \( \mathbf{L} \) is the angular momentum vector of the chunk, \( \mathbf{I} \) is its moment of inertia tensor, and \( \omega \) is omega = angular velocity of the chunk. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The compute chunk/atom command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

Note: The coordinates of an atom contribute to the chunk’s angular velocity in “unwrapped” form, by using the image flags associated with each atom. See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the set image command.

The simplest way to output the results of the compute omega/chunk calculation to a file is to use the fix ave/time command, for example:

```
compute ccl all chunk/atom molecule
compute myChunk all omega/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```
19.61.4 Output info

This compute calculates a global array where the number of rows = the number of chunks \textit{Nchunk} as calculated by the specified \textit{compute chunk/atom} command. The number of columns = 3 for the 3 xyz components of the angular velocity for each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the \textit{Howto output} doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in velocity/distance \textit{units}.

- one or more keyword/value pairs may be appended

\texttt{keyword = cutoff or nnn or degrees or components or chunksize}
\texttt{cutoff value = distance cutoff}
\texttt{nnn value = number of nearest neighbors}
\texttt{degrees values = nlvalues, l1, l2,...}
\texttt{wl value = yes or no}
\texttt{wl/hat value = yes or no}
\texttt{components value = ldegree}
\texttt{chunksize value = number of atoms in each pass}
19.62.2 Examples

```plaintext
compute 1 all orientorder/atom
compute 1 all orientorder/atom degrees 5 4 6 8 10 12 nnn NULL cutoff 1.5
compute 1 all orientorder/atom wl/hat yes
compute 1 all orientorder/atom components 6
```

19.62.3 Description

Define a computation that calculates a set of bond-orientational order parameters $Q_l$ for each atom in a group. These order parameters were introduced by Steinhardt et al. as a way to characterize the local orientational order in atomic structures. For each atom, $Q_l$ is a real number defined as follows:

$$Y_{lm} = \frac{1}{nnn} \sum_{j=1}^{nnn} Y_{lm}(\theta(r_{ij}), \phi(r_{ij}))$$

$$Q_l = \frac{4\pi}{2l+1} \sum_{m=-l}^{m=l} Y_{lm}Y_{lm}^*$$

The first equation defines the local order parameters as averages of the spherical harmonics $Y_{lm}$ for each neighbor. These are complex number components of the 3D analog of the 2D order parameter $q_n$, which is implemented as LAMMPS compute `hexorder/atom`. The summation is over the `nnn` nearest neighbors of the central atom. The angles $\theta$ and $\phi$ are the standard spherical polar angles defining the direction of the bond vector $r_{ij}$. The phase and sign of $Y_{lm}$ follow the standard conventions, so that $\text{sign}(Y_{ll}(0,0)) = (-1)^l$. The second equation defines $Q_l$, which is a rotationally invariant non-negative amplitude obtained by summing over all the components of degree $l$.

The optional keyword `cutoff` defines the distance cutoff used when searching for neighbors. The default value, also the maximum allowable value, is the cutoff specified by the pair style.

The optional keyword `nnn` defines the number of nearest neighbors used to calculate $Q_l$. The default value is 12. If the value is NULL, then all neighbors up to the specified distance cutoff are used.

The optional keyword `degrees` defines the list of order parameters to be computed. The first argument `nlvalues` is the number of order parameters. This is followed by that number of non-negative integers giving the degree of each order parameter. Because $Q_2$ and all odd-degree order parameters are zero for atoms in cubic crystals (see Steinhardt), the default order parameters are $Q_4$, $Q_6$, $Q_8$, $Q_{10}$, and $Q_{12}$. For the FCC crystal with `nnn` =12, $Q_4 = \sqrt{\frac{7}{192}} = 0.19094...$ The numerical values of all order parameters up to $Q_{12}$ for a range of commonly encountered high-symmetry structures are given in Table I of Mickel et al., and these can be reproduced with this compute.

The optional keyword `wl` will output the third-order invariants $W_l$ (see Eq. 1.4 in Steinhardt) for the same degrees as for the $Q_l$ parameters. For the FCC crystal with `nnn` =12, $W_4 = -\sqrt{\frac{7}{192}} = -0.19094...$ The numerical values of $W_l$ for a range of commonly encountered high-symmetry structures are given in Table I of Steinhardt, and these can be reproduced with this keyword.

The optional keyword `wl/hat` will output the normalized third-order invariants $\hat{W}_l$ (see Eq. 2.2 in Steinhardt) for the same degrees as for the $Q_l$ parameters. For the FCC crystal with `nnn` =12, $\hat{W}_4 = -\frac{7}{\sqrt{192}} = -0.159317...$ The numerical values of $\hat{W}_l$ for a range of commonly encountered high-symmetry structures are given in Table I of Steinhardt, and these can be reproduced with this keyword.

The optional keyword `components` will output the components of the normalized complex vector $\hat{Y}_{lm} = Y_{lm}/|Y_{lm}|$ of degree `ldegree`, which must be included in the list of order parameters to be computed. This option can be used in conjunction with `compute coord_atom` to calculate the ten Wolde’s criterion to identify crystal-like particles, as discussed in ten Wolde.

The optional keyword `chunksize` is only applicable when using the the KOKKOS package and is ignored otherwise. This keyword controls the number of atoms in each pass used to compute the bond-orientational order parameters and
is used to avoid running out of memory. For example if there are 4000 atoms in the simulation and the chunksize is set to 2000, the parameter calculation will be broken up into two passes.

The value of $Q_l$ is set to zero for atoms not in the specified compute group, as well as for atoms that have less than $nnn$ neighbors within the distance cutoff, unless $nnn$ is NULL.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

**Note:** If you have a bonded system, then the settings of special_bonds command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the special_bonds command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the order parameter. This difficulty can be circumvented by writing a dump file, and using the rerun command to compute the order parameter for snapshots in the dump file. The rerun script can use a special_bonds command that includes all pairs in the neighbor list.

Styles with a *gpu, intel, kk, omp, or opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 19.62.4 Output info

This compute calculates a per-atom array with nlvalues columns, giving the $Q_l$ values for each atom, which are real numbers on the range $0 \leq Q_l \leq 1$.

If the keyword $wl$ is set to yes, then the $W_l$ values for each atom will be added to the output array, which are real numbers.

If the keyword $wl/hat$ is set to yes, then the $\hat{W}_l$ values for each atom will be added to the output array, which are real numbers.

If the keyword components is set, then the real and imaginary parts of each component of normalized $\hat{Y}_{lm}$ will be added to the output array in the following order: $\text{Re}(\hat{Y}_{-m})$, $\text{Im}(\hat{Y}_{-m})$, $\text{Re}(\hat{Y}_{-m+1})$, $\text{Im}(\hat{Y}_{-m+1})$, ..., $\text{Re}(\hat{Y}_m)$, $\text{Im}(\hat{Y}_m)$.

In summary, the per-atom array will contain nlvalues columns, followed by an additional nlvalues columns if $wl$ is set to yes, followed by an additional nlvalues columns if $wl/hat$ is set to yes, followed by an additional $2*(2* ldegree+1)$ columns if the components keyword is set.

These values can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.
19.62.5 Restrictions

none

19.62.6 Related commands

compute coord/atom, compute centro/atom, compute hexorder/atom

19.62.7 Default

The option defaults are cutoff = pair style cutoff, nnn = 12, degrees = 5 4 6 8 10 12 i.e. \(Q_4\), \(Q_6\), \(Q_8\), \(Q_{10}\), and \(Q_{12}\), \(wl\) = no, \(wl/hat\) = no, \(components\) off, and \(chunksize\) = 2000

19.63 compute pair command

19.63.1 Syntax

\[
\text{compute ID group-ID pair pstyle \{nstyle\} \{evalue\}}
\]

- ID, group-ID are documented in compute command
- \(pair\) = style name of this compute command
- \(pstyle\) = style name of a pair style that calculates additional values
- \(nsub\) = \(n\)-instance of a sub-style, if a pair style is used multiple times in a hybrid style
- \(evalue\) = \(epair\) or \(evdwl\) or \(ecoul\) or blank (optional)

19.63.2 Examples

\[
\begin{array}{l}
\text{compute 1 all pair gauss} \\
\text{compute 1 all pair lj/cut/coul/cut ecoul} \\
\text{compute 1 all pair tersoff 2 epair} \\
\text{compute 1 all pair reax/c}
\end{array}
\]
19.63.3 Description

Define a computation that extracts additional values calculated by a pair style, and makes them accessible for output or further processing by other commands.

Note: The group specified for this command is ignored.

The specified *pstyle* must be a pair style used in your simulation either by itself or as a sub-style in a *pair_style hybrid* or *hybrid/overlay* command. If the sub-style is used more than once, an additional number *nsub* has to be specified in order to choose which instance of the sub-style will be used by the compute. Not specifying the number in this case will cause the compute to fail.

The *value* setting is optional. All pair styles tally a potential energy *epair* which may be broken into two parts: *evdwl* and *ecoul* such that *epair = evdwl + ecoul*. If the pair style calculates Coulombic interactions, their energy will be tallied in *ecoul*. Everything else (whether it is a Lennard-Jones style van der Waals interaction or not) is tallied in *evdwl*. If *value* is blank or specified as *epair*, then *epair* is stored as a global scalar by this compute. This is useful when using *pair_style hybrid* if you want to know the portion of the total energy contributed by one sub-style. If *value* is specified as *evdwl* or *ecoul*, then just that portion of the energy is stored as a global scalar.

Note: The energy returned by the *evdwl* keyword does not include tail corrections, even if they are enabled via the *pair_modify* command.

Some pair styles tally additional quantities, e.g. a breakdown of potential energy into 14 components is tallied by the *pair_style reax/c* command. These values (1 or more) are stored as a global vector by this compute. See the doc page for individual pair styles for info on these values.

19.63.4 Output info

This compute calculates a global scalar which is *epair* or *evdwl* or *ecoul*. If the pair style supports it, it also calculates a global vector of length >= 1, as determined by the pair style. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar and vector values calculated by this compute are “extensive”.

The scalar value will be in energy *units*. The vector values will typically also be in energy *units*, but see the doc page for the pair style for details.

19.63.5 Restrictions

none
19.63.6 Related commands

compute pe, compute bond

19.63.7 Default

The keyword defaults are \textit{value} = \textit{epair}, \textit{nsub} = 0.

19.64 compute pair/local command

19.64.1 Syntax

\begin{verbatim}
compute ID group-ID pair/local value1 value2 ... keyword args ...
\end{verbatim}

- ID, group-ID are documented in \textit{compute} command
- pair/local = style name of this compute command
- one or more values may be appended
- value = \textit{dist} or \textit{eng} or \textit{force} or \textit{fx} or \textit{fy} or \textit{fz} or \textit{pN}
  - \textit{dist} = pairwise distance
  - \textit{eng} = pairwise energy
  - \textit{force} = pairwise force
  - \textit{fx}, \textit{fy}, \textit{fz} = components of pairwise force
  - \textit{pN} = pair style specific quantities for allowed N values
- zero or more keyword/arg pairs may be appended
- keyword = \textit{cutoff}
  - \textit{cutoff} arg = \textit{type} or \textit{radius}

19.64.2 Examples

\begin{verbatim}
compute 1 all pair/local eng
compute 1 all pair/local dist eng force
compute 1 all pair/local dist eng fx fy fz
compute 1 all pair/local dist fx fy fz p1 p2 p3
\end{verbatim}

19.64.3 Description

Define a computation that calculates properties of individual pairwise interactions. The number of datums generated, aggregated across all processors, equals the number of pairwise interactions in the system.

The local data stored by this command is generated by looping over the pairwise neighbor list. Info about an individual pairwise interaction will only be included if both atoms in the pair are in the specified compute group, and if the current pairwise distance is less than the force cutoff distance for that interaction, as defined by the \textit{pair_style} and \textit{pair_coeff} commands.

The value \textit{dist} is the distance between the pair of atoms.

The value \textit{eng} is the interaction energy for the pair of atoms.
The value \textit{force} is the force acting between the pair of atoms, which is positive for a repulsive force and negative for an attractive force. The values $f_x$, $f_y$, and $f_z$ are the xyz components of \textit{force} on atom I.

A pair style may define additional pairwise quantities which can be accessed as $p1$ to $pN$, where N is defined by the pair style. Most pair styles do not define any additional quantities, so $N = 0$. An example of ones that do are the \textit{granular pair styles} which calculate the tangential force between two particles and return its components and magnitude acting on atom I for $N = 1,2,3,4$. See individual pair styles for details.

When using $pN$ with pair style \textit{hybrid}, the output will be the Nth quantity from the sub-style that computes the pairwise interaction (based on atom types). If that sub-style does not define a $pN$, the output will be 0.0. The maximum allowed N is the maximum number of quantities provided by any sub-style.

When using $pN$ with pair style \textit{hybrid/overlay} the quantities from all sub-styles that provide them are concatenated together into one long list. For example, if there are 3 sub-styles and 2 of them have additional output (with 3 and 4 quantities, respectively), then 7 values ($p1$ up to $p7$) are defined. The values $p1$ to $p3$ refer to quantities defined by the first of the two sub-styles. Values $p4$ to $p7$ refer to quantities from the second of the two sub-styles. If the referenced $pN$ is not computed for the specific pairwise interaction (based on atom types), then the output will be 0.0.

The value $\textit{dist}$ will be in distance \textit{units}. The value $\textit{eng}$ will be in energy \textit{units}. The values $\textit{force}$, $f_x$, $f_y$, and $f_z$ will be in force \textit{units}. The values $pN$ will be in whatever units the pair style defines.

The optional \textit{cutoff} keyword determines how the force cutoff distance for an interaction is determined. For the default setting of \textit{type}, the pairwise cutoff defined by the \textit{pair_style} command for the types of the two atoms is used. For the \textit{radius} setting, the sum of the radii of the two particles is used as a cutoff. For example, this is appropriate for granular particles which only interact when they are overlapping, as computed by \textit{granular pair styles}. Note that if a granular model defines atom types such that all particles of a specific type are monodisperse (same diameter), then the two settings are effectively identical.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, pair output from the \textit{compute property/local} command can be combined with data from this command and output by the \textit{dump local} command in a consistent way.

Here is an example of how to do this:

```
compute 1 all property/local patom1 patom2
compute 2 all pair/local dist eng force
```

\textbf{Note:} For pairs, if two atoms LJ are involved in 1-2, 1-3, 1-4 interactions within the molecular topology, their pairwise interaction may be turned off, and thus they may not appear in the neighbor list, and will not be part of the local data created by this command. More specifically, this will be true of LJ pairs with a weighting factor of 0.0; pairs with a non-zero weighting factor are included. The weighting factors for 1-2, 1-3, and 1-4 pairwise interactions are set by the \textit{special_bonds} command. An exception is if long-range Coulombics are being computed via the \textit{kspace_style} command, then atom pairs with weighting factors of zero are still included in the neighbor list, so that a portion of the long-range interaction contribution can be computed in the pair style. Hence in that case, those atom pairs will be part of the local data created by this command.
19.64.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of pairs. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The output for dist will be in distance units. The output for eng will be in energy units. The output for force, fx, fy, and fz will be in force units. The output for pN will be in whatever units the pair style defines.

19.64.5 Restrictions

none

19.64.6 Related commands

19.64.7 Default

The keyword default is cutoff = type.

19.65 compute pe command

19.65.1 Syntax

compute ID group-ID pe keyword ... 

- ID, group-ID are documented in compute command
- pe = style name of this compute command
- zero or more keywords may be appended
- keyword = pair or bond or angle or dihedral or improper or kspace or fix

19.65.2 Examples

compute 1 all pe
compute molPE all pe bond angle dihedral improper
19.65.3 Description

Define a computation that calculates the potential energy of the entire system of atoms. The specified group must be “all”. See the `compute pe/atom` command if you want per-atom energies. These per-atom values could be summed for a group of atoms via the `compute reduce` command.

The energy is calculated by the various pair, bond, etc potentials defined for the simulation. If no extra keywords are listed, then the potential energy is the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix energy. I.e. it is as if all the keywords were listed. If any extra keywords are listed, then only those components are summed to compute the potential energy.

The Kspace contribution requires 1 extra FFT each timestep the energy is calculated, if using the PPPM solver via the `kspace_style ppm` command. Thus it can increase the cost of the PPPM calculation if it is needed on a large fraction of the simulation timesteps.

Various fixes can contribute to the total potential energy of the system if the `fix` contribution is included. See the doc pages for `individual fixes` for details of which ones compute a potential energy.

---

**Note:** The `fix_modify energy yes` command must also be specified if a fix is to contribute potential energy to this command.

---

A compute of this style with the ID of “thermo_pe” is created when LAMMPS starts up, as if this command were in the input script:

```
compute thermo_pe all pe
```

See the “thermo_style” command for more details.

---

19.65.4 Output info

This compute calculates a global scalar (the potential energy). This value can be used by any command that uses a global scalar value from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy units.

19.66 compute pe/atom command

19.66.1 Syntax

```
compute ID group-ID pe/atom keyword ...  
```

- ID, group-ID are documented in `compute` command
- `pe/atom = style name of this compute command`
- zero or more keywords may be appended
- `keyword = pair or bond or angle or dihedral or improper or kspace or fix`

19.66.2 Examples

```
compute 1 all pe/atom
compute 1 all pe/atom pair
compute 1 all pe/atom pair bond
```

19.66.3 Description

Define a computation that computes the per-atom potential energy for each atom in a group. See the `compute pe` command if you want the potential energy of the entire system.

The per-atom energy is calculated by the various pair, bond, etc potentials defined for the simulation. If no extra keywords are listed, then the potential energy is the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix energy. I.e. it is as if all the keywords were listed. If any extra keywords are listed, then only those components are summed to compute the potential energy.

Note that the energy of each atom is due to its interaction with all other atoms in the simulation, not just with other atoms in the group.

For an energy contribution produced by a small set of atoms (e.g. 4 atoms in a dihedral or 3 atoms in a Tersoff 3-body interaction), that energy is assigned in equal portions to each atom in the set. E.g. 1/4 of the dihedral energy to each of the 4 atoms.

The `dihedral_style charmm` style calculates pairwise interactions between 1-4 atoms. The energy contribution of these terms is included in the pair energy, not the dihedral energy.

The KSpace contribution is calculated using the method in (Heyes) for the Ewald method and a related method for PPPM, as specified by the `kspace_style ppm` command. For PPPM, the calculation requires 1 extra FFT each timestep that per-atom energy is calculated. This document describes how the long-range per-atom energy calculation is performed.

Various fixes can contribute to the per-atom potential energy of the system if the `fix` contribution is included. See the doc pages for `individual fixes` for details of which ones compute a per-atom potential energy.
Note: The `fix_modify energy yes` command must also be specified if a fix is to contribute per-atom potential energy to this command.

As an example of per-atom potential energy compared to total potential energy, these lines in an input script should yield the same result in the last 2 columns of thermo output:

```plaintext
compute peratom all pe/atom
compute pe all reduce sum c_peratom
thermo_style custom step temp etotal press pe c_pe
```

Note: The per-atom energy does not include any Lennard-Jones tail corrections to the energy added by the `pair_modify tail yes` command, since those are contributions to the global system energy.

### 19.66.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options. The per-atom vector values will be in energy units.

```

- ID, group-ID are documented in compute command
- plasticity/atom = style name of this compute command
19.67.2 Examples

```plaintext
compute 1 all plasticity/atom
```

19.67.3 Description

Define a computation that calculates the per-atom plasticity for each atom in a group. This is a quantity relevant for Peridynamics models. See this document for an overview of LAMMPS commands for Peridynamics modeling.

The plasticity for a Peridynamic particle is the so-called consistency parameter (\(\lambda\)). For elastic deformation \(\lambda = 0\), otherwise \(\lambda > 0\) for plastic deformation. For details, see (Mitchell) and the PDF doc included in the LAMMPS distribution in `doc/PDF/PDLammps_EPS.pdf`.

This command can be invoked for one of the Peridynamic pair styles: peri/eps.

The plasticity value will be 0.0 for atoms not in the specified compute group.

19.67.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector values are unitless numbers (\(\lambda\)) \(\geq 0.0\).

19.67.5 Restrictions

This compute is part of the PERI package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

```

- ID, group-ID are documented in `compute` command
• pressure = style name of this compute command
• temp-ID = ID of compute that calculates temperature, can be NULL if not needed
• zero or more keywords may be appended
• keyword = ke or pair or bond or angle or dihedral or improper or kspace or fix or virial or pair/hybrid

19.68.2 Examples

```plaintext
compute 1 all pressure thermo_temp
compute 1 all pressure NULL pair bond
compute 1 all pressure NULL pair/hybrid lj/cut
```

19.68.3 Description

Define a computation that calculates the pressure of the entire system of atoms. The specified group must be “all”. See the `compute stress/atom` command if you want per-atom pressure (stress). These per-atom values could be summed for a group of atoms via the `compute reduce` command.

The pressure is computed by the formula

\[ P = \frac{Nk_B T}{V} + \sum_{k} r_k \cdot f_k \]

where \( N \) is the number of atoms in the system (see discussion of DOF below), \( k_B \) is the Boltzmann constant, \( T \) is the temperature, \( d \) is the dimensionality of the system (2 or 3 for 2d/3d), and \( V \) is the system volume (or area in 2d). The second term is the virial, equal to \(-dU/dV\), computed for all pairwise as well as 2-body, 3-body, 4-body, many-body, and long-range interactions, where \( r_k \) and \( f_k \) are the position and force vector of atom \( i \), and the black dot indicates a dot product. When periodic boundary conditions are used, \( N' \) necessarily includes periodic image (ghost) atoms outside the central box, and the position and force vectors of ghost atoms are thus included in the summation. When periodic boundary conditions are not used, \( N' = N = \) the number of atoms in the system. Fixes that impose constraints (e.g. the `fix shake` command) also contribute to the virial term.

A symmetric pressure tensor, stored as a 6-element vector, is also calculated by this compute. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz. The equation for the I,J components (where I and J = x,y,z) is similar to the above formula, except that the first term uses components of the kinetic energy tensor and the second term uses components of the virial tensor:

\[ P_{I,J} = \sum_{k} \frac{m_k v_{k,I} v_{k,J}}{V} + \sum_{k} \frac{r_{k,I} f_{k,J}}{V} \]

If no extra keywords are listed, the entire equations above are calculated. This includes a kinetic energy (temperature) term and the virial as the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix contributions to the force on each atom. If any extra keywords are listed, then only those components are summed to compute temperature or ke and/or the virial. The `virial` keyword means include all terms except the kinetic energy `ke`.

The `pair/hybrid` keyword means to only include contribution from a sub-style in a hybrid or hybrid/overlay pair style.

Details of how LAMMPS computes the virial efficiently for the entire system, including for many-body potentials and accounting for the effects of periodic boundary conditions are discussed in (Thompson).

The temperature and kinetic energy tensor is not calculated by this compute, but rather by the temperature compute specified with the command. If the kinetic energy is not included in the pressure, than the temperature compute is not used and can be specified as NULL. Normally the temperature compute used by compute pressure should calculate the temperature of all atoms for consistency with the virial term, but any compute style that calculates temperature can be used, e.g. one that excludes frozen atoms or other degrees of freedom.
Note that if desired the specified temperature compute can be one that subtracts off a bias to calculate a temperature using only the thermal velocity of the atoms, e.g., by subtracting a background streaming velocity. See the doc pages for individual compute commands to determine which ones include a bias.

Also note that the N in the first formula above is really degrees-of-freedom divided by d = dimensionality, where the DOF value is calculated by the temperature compute. See the various compute temperature styles for details.

A compute of this style with the ID of “thermo_press” is created when LAMMPS starts up, as if this command were in the input script:

```plaintext
compute thermo_press all pressure thermo_temp
```

where “thermo_temp” is the ID of a similarly defined compute of style “temp”. See the “thermo_style” command for more details.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 19.68.4 Output info

This compute calculates a global scalar (the pressure) and a global vector of length 6 (pressure tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar and vector values calculated by this compute are “intensive”. The scalar and vector values will be in pressure units.

19.69  compute pressure/cylinder command

19.69.1  Syntax

\texttt{compute ID group-ID pressure/cylinder zlo zhi Rmax bin_width}

• ID, group-ID are documented in \texttt{compute} command
• pressure/cylinder = style name of this compute command
• zlo = minimum z-boundary for cylinder
• zhi = maximum z-boundary for cylinder
• Rmax = maximum radius to perform calculation to
• bin_width = width of radial bins to use for calculation

19.69.2  Examples

\texttt{compute 1 all pressure/cylinder -10.0 10.0 15.0 0.25}

19.69.3  Description

Define a computation that calculates the pressure tensor of a system in cylindrical coordinates, as discussed in \textit{(Addington)}. This is useful for systems with a single axis of rotational symmetry, such as cylindrical micelles or carbon nanotubes. The compute splits the system into radial, cylindrical-shell-type bins of width bin_width, centered at x=0,y=0, and calculates the radial (P_{rhorho}), azimuthal (P_{phiphii}), and axial (P_{zz}) components of the configurational pressure tensor. The local density is also calculated for each bin, so that the true pressure can be recovered as P_{kin}+P_{conf}=density*k*T+P_{conf}. The output is a global array with 5 columns; one each for bin radius, local number density, P_{rhorho}, P_{phiphii}, and P_{zz}. The number of rows is governed by the values of Rmax and bin_width. Pressure tensor values are output in pressure units.

19.69.4  Output info

This compute calculates a global array with 5 columns and Rmax/bin_width rows. The output columns are: R (distance units), number density (inverse volume units), configurational radial pressure (pressure units), configurational azimuthal pressure (pressure units), and configurational axial pressure (pressure units).

The values calculated by this compute are “intensive”. The pressure values will be in pressure \textit{units}. The number density values will be in inverse volume \textit{units}. 

19.69. compute pressure/cylinder command 1577
19.69.5 Restrictions

This compute currently calculates the pressure tensor contributions for pair styles only (i.e. no bond, angle, dihedral, etc. contributions and in the presence of bonded interactions, the result will be incorrect due to exclusions for special bonds) and requires pair-wise force calculations not available for most many-body pair styles. K-space calculations are also excluded. Note that this pressure compute outputs the configurational terms only; the kinetic contribution is not included and may be calculated from the number density output by \( P_{\text{kin}} = \text{density} \times k \times T \).

This compute is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

compute 1 all property/atom xs vx fx mux
compute 2 all property/atom type
compute 1 all property/atom ix iy iz
compute 3 all property/atom sp spx spy spz
```

19.71.3 Description

Define a computation that simply stores atom attributes for each atom in the group. This is useful so that the values can be used by other output commands that take computes as inputs. See for example, the compute reduce, fix ave/atom, fix ave/histo, fix ave/chunk, and atom-style variable commands.

The list of possible attributes is the same as that used by the dump custom command, which describes their meaning, with some additional quantities that are only defined for certain atom styles. Basically, this augmented list gives an input script access to any per-atom quantity stored by LAMMPS.

The values are stored in a per-atom vector or array as discussed below. Zeroes are stored for atoms not in the specified group or for quantities that are not defined for a particular particle in the group (e.g. shapex if the particle is not an ellipsoid).

The additional quantities only accessible via this command, and not directly via the dump custom command, are as follows.

* Shapex, shapey, and shapez are defined for ellipsoidal particles and define the 3d shape of each particle.
* Quatw, quati, quatj, and quatk are defined for ellipsoidal particles and body particles and store the 4-vector quaternion representing the orientation of each particle. See the set command for an explanation of the quaternion vector.
* End1x, end1y, end1z, end2x, end2y, end2z, are defined for line segment particles and define the end points of each line segment.
* Corner1x, corner1y, corner1z, corner2x, corner2y, corner2z, corner3x, corner3y, corner3z, are defined for triangular particles and define the corner points of each triangle.
* Nbonds is available for all molecular atom styles and refers to the number of explicit bonds assigned to an atom. Note that if the newton bond command is set to on, which is the default, then every bond in the system is assigned to only one of the two atoms in the bond. Thus a bond between atoms I,J may be tallied for either atom I or atom J. If newton bond off is set, it will be tallied with both atom I and atom J.

The i_name and d_name attributes refer to custom integer and floating-point properties that have been added to each atom via the fix property/atom command. When that command is used specific names are given to each attribute which are what is specified as the “name” portion of i_name or d_name.

19.71.4 Output info

This compute calculates a per-atom vector or per-atom array depending on the number of input values. If a single input is specified, a per-atom vector is produced. If two or more inputs are specified, a per-atom array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The vector or array values will be in whatever units the corresponding attribute is in, e.g. velocity units for vx, charge units for q, etc.

For the spin quantities, sp is in the units of the Bohr magneton, spx, spy, and spz are unitless quantities, and fm, fmy and fmz are given in rad/THz.

19.72 compute property/chunk command

19.72.1 Syntax

```plaintext
compute ID group-ID property/chunk chunkID input1 input2 ...
```

- ID, group-ID are documented in compute command
- property/chunk = style name of this compute command
- input = one or more attributes
  - attributes = count, id, coord1, coord2, coord3
  - count = # of atoms in chunk
  - id = original chunk IDs before compression by compute chunk/atom
  - coord123 = coordinates for spatial bins calculated by compute chunk/atom

19.72.2 Examples

```plaintext
compute 1 all property/chunk count
compute 1 all property/chunk ID coord1
```

19.72.3 Description

Define a computation that stores the specified attributes of chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and Howto chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates and stores the specified attributes of chunks as global data so they can be accessed by other output commands and used in conjunction with other commands that generate per-chunk data, such as compute com/chunk or compute msd/chunk.

Note that only atoms in the specified group contribute to the calculation of the count attribute. The compute chunk/atom command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.
The `count` attribute is the number of atoms in the chunk. The `id` attribute stores the original chunk ID for each chunk. It can only be used if the `compress` keyword was set to `yes` for the `compute chunk/atom` command referenced by chunkID. This means that the original chunk IDs (e.g., molecule IDs) will have been compressed to remove chunk IDs with no atoms assigned to them. Thus a compressed chunk ID of 3 may correspond to an original chunk ID (molecule ID in this case) of 415. The `id` attribute will then be 415 for the third chunk.

The `coordN` attributes can only be used if a binning style was used in the `compute chunk/atom` command referenced by chunkID. For `bin/1d`, `bin/2d`, and `bin/3d` styles the attribute is the center point of the bin in the corresponding dimension. Style `bin/1d` only defines a `coord1` attribute. Style `bin/2d` adds a `coord2` attribute. Style `bin/3d` adds a `coord3` attribute.

Note that if the value of the `units` keyword used in the `compute chunk/atom` command is `box` or `lattice`, the `coordN` attributes will be in distance units. If the value of the `units` keyword is `reduced`, the `coordN` attributes will be in unitless reduced units (0-1).

The simplest way to output the results of the compute property/chunk calculation to a file is to use the `fix ave/time` command, for example:

```plaintext
compute ccl all chunk/atom molecule
compute myChunk1 all property/chunk ccl count
compute myChunk2 all com/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk1 c_myChunk2[*] file tmp.out mode vector
```

### 19.72.4 Output info

This compute calculates a global vector or global array depending on the number of input values. The length of the vector or number of rows in the array is the number of chunks.

This compute calculates a global vector or global array where the number of rows = the number of chunks \( N_{chunk} \) as calculated by the specified `compute chunk/atom` command. If a single input is specified, a global vector is produced. If two or more inputs are specified, a global array is produced where the number of columns = the number of inputs.

The vector or array can be accessed by any command that uses global values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The vector or array values are “intensive”. The values will be unitless or in the units discussed above.

                  iatom1 iatom2 iatom3 iatom4 itype
```

- natom1, natom2 = IDs of 2 atoms in each pair (within neighbor cutoff)
- ntype1, ntype2 = type of 2 atoms in each pair (within neighbor cutoff)
- patom1, patom2 = IDs of 2 atoms in each pair (within force cutoff)
- ptype1, ptype2 = type of 2 atoms in each pair (within force cutoff)
- batom1, batom2 = IDs of 2 atoms in each bond
- btype = bond type of each bond
- aatom1, aatom2, aatom3 = IDs of 3 atoms in each angle
- atype = angle type of each angle
- datom1, datom2, datom3, datom4 = IDs of 4 atoms in each dihedral
- dtype = dihedral type of each dihedral
- iatom1, iatom2, iatom3, iatom4 = IDs of 4 atoms in each improper
- itype = improper type of each improper

- zero or more keyword/arg pairs may be appended
- keyword = cutoff
  - cutoff arg = type or radius

19.73.2 Examples

```
compute 1 all property/local btype batom1 batom2
compute 1 all property/local atype aatom2
```
19.73.3 Description

Define a computation that stores the specified attributes as local data so it can be accessed by other output commands. If the input attributes refer to bond information, then the number of datums generated, aggregated across all processors, equals the number of bonds in the system. Ditto for pairs, angles, etc.

If multiple attributes are specified then they must all generate the same amount of information, so that the resulting local array has the same number of rows for each column. This means that only bond attributes can be specified together, or angle attributes, etc. Bond and angle attributes can not be mixed in the same compute property/local command.

If the inputs are pair attributes, the local data is generated by looping over the pairwise neighbor list. Info about an individual pairwise interaction will only be included if both atoms in the pair are in the specified compute group. For natom1 and natom2, all atom pairs in the neighbor list are considered (out to the neighbor cutoff = force cutoff + neighbor skin). For patom1 and patom2, the distance between the atoms must be less than the force cutoff distance for that pair to be included, as defined by the pair_style and pair_coeff commands.

The optional cutoff keyword determines how the force cutoff distance for an interaction is determined for the patom1 and patom2 attributes. For the default setting of type, the pairwise cutoff defined by the pair_style command for the types of the two atoms is used. For the radius setting, the sum of the radii of the two particles is used as a cutoff. For example, this is appropriate for granular particles which only interact when they are overlapping, as computed by granular pair styles. Note that if a granular model defines atom types such that all particles of a specific type are monodisperse (same diameter), then the two settings are effectively identical.

If the inputs are bond, angle, etc attributes, the local data is generated by looping over all the atoms owned on a processor and extracting bond, angle, etc info. For bonds, info about an individual bond will only be included if both atoms in the bond are in the specified compute group. Likewise for angles, dihedrals, etc.

For bonds and angles, a bonds/angles that have been broken by setting their bond/angle type to 0 will not be included. Bonds/angles that have been turned off (see the fix shake or delete_bonds commands) by setting their bond/angle type negative are written into the file. This is consistent with the compute bond/local and compute angle/local commands.

Note: For pairs, if two atoms I,J are involved in 1-2, 1-3, 1-4 interactions within the molecular topology, their pairwise interaction may be turned off, and thus they may not appear in the neighbor list, and will not be part of the local data created by this command. More specifically, this may be true of I,J pairs with a weighting factor of 0.0; pairs with a non-zero weighting factor are included. The weighting factors for 1-2, 1-3, and 1-4 pairwise interactions are set by the special_bonds command.

The natom1 and natom2, or patom1 and patom2 attributes refer to the atom IDs of the 2 atoms in each pairwise interaction computed by the pair_style command. The ntype1 and ntype2, or ptype1 and ptype2 attributes refer to the atom types of the 2 atoms in each pairwise interaction.

The batom1 and batom2 attributes refer to the atom IDs of the 2 atoms in each bond. The btype attribute refers to the type of the bond, from 1 to Nbtypes = # of bond types. The number of bond types is defined in the data file read by the read_data command.

The attributes that start with “a”, “d”, “i”, refer to similar values for angles, dihedrals, and impropers.
19.73.4 Output info

This compute calculates a local vector or local array depending on the number of input values. The length of the vector or number of rows in the array is the number of bonds, angles, etc. If a single input is specified, a local vector is produced. If two or more inputs are specified, a local array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The vector or array values will be integers that correspond to the specified attribute.

19.74 compute ptm/atom command

19.74.1 Syntax

```
compute ID group-ID ptm/atom structures threshold group2-ID
```

- ID, group-ID are documented in compute command
- ptm/atom = style name of this compute command
- structures = structure types to search for
- threshold = lattice distortion threshold (RMSD)
- group2-ID determines which group is used for neighbor selection (optional, default “all”)

19.74.2 Examples

```
compute 1 all ptm/atom default 0.1 all
compute 1 all ptm/atom fcc-hcp-dcub-dhex 0.15 all
compute 1 all ptm/atom all 0
```
19.74.3 Description

Define a computation that determines the local lattice structure around an atom using the PTM (Polyhedral Template Matching) method. The PTM method is described in (Larsen).

Currently, there are seven lattice structures PTM recognizes:

- fcc = 1
- hcp = 2
- bcc = 3
- ico (icosahedral) = 4
- sc (simple cubic) = 5
- dcub (diamond cubic) = 6
- dhex (diamond hexagonal) = 7
- graphene = 8

The value of the PTM structure will be 0 for unknown types and -1 for atoms not in the specified compute group. The choice of structures to search for can be specified using the “structures” argument, which is a hyphen-separated list of structure keywords. Two convenient pre-set options are provided:

- default: fcc-hcp-bcc-ico
- all: fcc-hcp-bcc-ico-sc-dcub-dhex-graphene

The ‘default’ setting detects the same structures as the Common Neighbor Analysis method. The ‘all’ setting searches for all structure types. A performance penalty is incurred for the diamond and graphene structures, so it is not recommended to use this option if it is known that the simulation does not contain these structures.

PTM identifies structures using two steps. First, a graph isomorphism test is used to identify potential structure matches. Next, the deviation is computed between the local structure (in the simulation) and a template of the ideal lattice structure. The deviation is calculated as:

\[
RMSD(u, v) = \min_{s, Q} \sqrt{\frac{1}{N} \sum_{i=1}^{N} ||s[u_i - \bar{u}] - Q[v_i]|^2}
\]

Here, u and v contain the coordinates of the local and ideal structures respectively, s is a scale factor, and Q is a rotation. The best match is identified by the lowest RMSD value, using the optimal scaling, rotation, and correspondence between the points.

The ‘threshold’ keyword sets an upper limit on the maximum permitted deviation before a local structure is identified as disordered. Typical values are in the range 0.1-0.15, but larger values may be desirable at higher temperatures. A value of 0 is equivalent to infinity and can be used if no threshold is desired.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a ptm/atom style. By default the compute processes all neighbors unless the optional group2-ID argument is given, then only members of that group are considered as neighbors.
19.74.4 Output info

This compute calculates a per-atom array, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

Results are stored in the per-atom array in the following order:

- type
- rmsd
- interatomic distance
- qw
- qx
- qy
- qz

The type is a number from -1 to 8. The rmsd is a positive real number. The interatomic distance is computed from the scale factor in the RMSD equation. The (qw,qx,qy,qz) parameters represent the orientation of the local structure in quaternion form. The reference coordinates for each template (from which the orientation is determined) can be found in the `ptm_constants.h` file in the PTM source directory. For atoms that are not within the compute group-ID, all values are set to zero.

19.74.5 Restrictions

This fix is part of the USER-PTM package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

</tr>
</tbody>
</table>

19.75.3 Description

Define a computation that calculates the radial distribution function (RDF), also called g(r), and the coordination number for a group of particles. Both are calculated in histogram form by binning pairwise distances into \( N_{bin} \) bins from 0.0 to the maximum force cutoff defined by the \texttt{pair_style} command or the cutoff distance \( R_{cut} \) specified via the \texttt{cutoff} keyword. The bins are of uniform size in radial distance. Thus a single bin encompasses a thin shell of distances in 3d and a thin ring of distances in 2d.

\textbf{Note:} If you have a bonded system, then the settings of \texttt{special_bonds} command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the \texttt{special_bonds} command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses a neighbor list, it also means those pairs will not be included in the RDF. This does not apply when using long-range coulomb interactions (coul/long, coul/msm, coul/wolf) or similar. One way to get around this would be to set special_bond scaling factors to very tiny numbers that are not exactly zero (e.g. 1.0e-50). Another workaround is to write a dump file, and use the \texttt{rerun} command to compute the RDF for snapshots in the dump file. The rerun script can use a \texttt{special_bonds} command that includes all pairs in the neighbor list.

By default the RDF is computed out to the maximum force cutoff defined by the \texttt{pair_style} command. If the \texttt{cutoff} keyword is used, then the RDF is computed accurately out to the \( R_{cut} > 0.0 \) distance specified.

\textbf{Note:} Normally, you should only use the \texttt{cutoff} keyword if no pair style is defined, e.g. the \texttt{rerun} command is being used to post-process a dump file of snapshots. Or if you really want the RDF for distances beyond the \texttt{pair_style} force cutoff and cannot easily post-process a dump file to calculate it. This is because using the \texttt{cutoff} keyword incurs extra computation and possibly communication, which may slow down your simulation. If you specify a \( R_{cut} <= \) force cutoff, you will force an additional neighbor list to be built at every timestep this command is invoked (or every reneighboring timestep, whichever is less frequent), which is inefficient. LAMMPS will warn you if this is the case. If you specify a \( R_{cut} > \) force cutoff, you must insure ghost atom information out to \( R_{cut} + \text{skin} \) is communicated, via the \texttt{comm_modify cutoff} command, else the RDF computation cannot be performed, and LAMMPS will give an error message. The \text{skin} value is whatever is specified with the \texttt{neighbor} command. In this case, you are forcing a large neighbor list to be built just for the RDF computation, and extra communication to be performed every timestep.
The *itype* and *jtype* arguments are optional. These arguments must come in pairs. If no pairs are listed, then a single histogram is computed for g(r) between all atom types. If one or more pairs are listed, then a separate histogram is generated for each *itype*,*jtype* pair.

The *itype* and *jtype* settings can be specified in one of two ways. An explicit numeric value can be used, as in the fourth example above. Or a wild-card asterisk can be used to specify a range of atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

If both *itype* and *jtype* are single values, as in the fourth example above, this means that a g(r) is computed where atoms of type *itype* are the central atom, and atoms of type *jtype* are the distribution atom. If either *itype* and *jtype* represent a range of values via the wild-card asterisk, as in the fifth example above, this means that a g(r) is computed where atoms of any of the range of types represented by *itype* are the central atom, and atoms of any of the range of types represented by *jtype* are the distribution atom.

Pairwise distances are generated by looping over a pairwise neighbor list, just as they would be in a pair_style computation. The distance between two atoms I and J is included in a specific histogram if the following criteria are met:

- atoms I,J are both in the specified compute group
- the distance between atoms I,J is less than the maximum force cutoff
- the type of the I atom matches *itype* (one or a range of types)
- the type of the J atom matches *jtype* (one or a range of types)

It is OK if a particular pairwise distance is included in more than one individual histogram, due to the way the *itype* and *jtype* arguments are specified.

The g(r) value for a bin is calculated from the histogram count by scaling it by the idealized number of how many counts there would be if atoms of type *jtype* were uniformly distributed. Thus it involves the count of *itype* atoms, the count of *jtype* atoms, the volume of the entire simulation box, and the volume of the bin’s thin shell in 3d (or the area of the bin’s thin ring in 2d).

A coordination number coord(r) is also calculated, which is the number of atoms of type *jtype* within the current bin or closer, averaged over atoms of type *itype*. This is calculated as the area- or volume-weighted sum of g(r) values over all bins up to and including the current bin, multiplied by the global average volume density of atoms of type *jtype*.

The simplest way to output the results of the compute rdf calculation to a file is to use the fix ave/time command, for example:

```
compute myRDF all rdf 50
fix 1 all ave/time 100 1 100 c_myRDF[*] file tmp.rdf mode vector
```

### 19.75.4 Output info

This compute calculates a global array with the number of rows = Nbins, and the number of columns = 1 + 2*Npairs, where Npairs is the number of IJ pairings specified. The first column has the bin coordinate (center of the bin). Each successive set of 2 columns has the g(r) and coord(r) values for a specific set of *itype* versus *jtype* interactions, as described above. These values can be used by any command that uses a global values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The array values calculated by this compute are all “intensive”.

The first column of array values will be in distance units. The g(r) columns of array values are normalized numbers >= 0.0. The coordination number columns of array values are also numbers >= 0.0.
19.75.5 Restrictions

The RDF is not computed for distances longer than the force cutoff, since processors (in parallel) don’t know about atom coordinates for atoms further away than that distance. If you want an RDF for larger distances, you can use the rerun command to post-process a dump file and set the cutoff for the potential to be longer in the rerun script. Note that in the rerun context, the force cutoff is arbitrary, since you are not running dynamics and thus are not changing your model. The definition of g(r) used by LAMMPS is only appropriate for characterizing atoms that are uniformly distributed throughout the simulation cell. In such cases, the coordination number is still correct and meaningful. As an example, if a large simulation cell contains only one atom of type itypeN and one of jtypeN, then g(r) will register an arbitrarily large spike at whatever distance they happen to be at, and zero everywhere else. Coord(r) will show a step change from zero to one at the location of the spike in g(r).

Note: compute rdf can handle dynamic groups and systems where atoms are added or removed, but this causes that certain normalization parameters need to be re-computed in every step and include collective communication operations. This will reduce performance and limit parallel efficiency and scaling. For systems, where only the type of atoms changes (e.g. when using fix atom/swap), you need to explicitly request the dynamic normalization updates via compute_modify dynamic yes

compute 3 fluid reduce max c_index[1] c_index[2] c_dist replace 1 3 replace 2 3
\end{verbatim}

### 19.77.3 Description

Define a calculation that “reduces” one or more vector inputs into scalar values, one per listed input. The inputs can be per-atom or local quantities; they cannot be global quantities. Atom attributes are per-atom quantities, \textit{computes} and \textit{fixes} may generate any of the three kinds of quantities, and \textit{atom-style variables} generate per-atom quantities. See the \texttt{variable} command and its special functions which can perform the same operations as the compute reduce command on global vectors.

The reduction operation is specified by the \textit{mode} setting. The \textit{sum} option adds the values in the vector into a global total. The \textit{min} or \textit{max} options find the minimum or maximum value across all vector values. The \textit{ave} setting adds the vector values into a global total, then divides by the number of values in the vector. The \textit{sumsq} option sums the square of the values in the vector into a global total. The \textit{avesq} setting does the same as \textit{sumsq}, then divides the sum of squares by the number of values. The last two options can be useful for calculating the variance of some quantity, e.g.\ variance = \textit{sumsq} - \textit{ave}^2.

Each listed input is operated on independently. For per-atom inputs, the group specified with this command means only atoms within the group contribute to the result. For per-atom inputs, if the compute reduce/region command is used, the atoms must also currently be within the region. Note that an input that produces per-atom quantities may define its own group which affects the quantities it returns. For example, if a compute is used as an input which generates a per-atom vector, it will generate values of 0.0 for atoms that are not in the group specified for that compute.

Each listed input can be an atom attribute (position, velocity, force component) or can be the result of a \texttt{compute} or \texttt{fix} or the evaluation of an atom-style \texttt{variable}.

Note that for values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If \(N\) = the size of the vector (for \textit{mode} = scalar) or the number of columns in the array (for \textit{mode} = vector), then an asterisk with no numeric values means all indices from 1 to \(N\). A leading asterisk means all indices from 1 to \(n\) (inclusive). A trailing asterisk means all indices from \(n\) to \(N\) (inclusive). A middle asterisk means all indices from \(m\) to \(n\) (inclusive).
Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 compute reduce commands are equivalent, since the `compute stress/atom` command creates a per-atom array with 6 columns:

```
compute myPress all stress/atom NULL
compute 2 all reduce min c_myPress[*]
```

The atom attribute values (x,y,z,vx,vy,vz,fx,fy,fz) are self-explanatory. Note that other atom attributes can be used as inputs to this fix by using the `compute property/atom` command and then specifying an input value from that compute.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. Computes can generate per-atom or local quantities. See the individual `compute` doc page for details. If no bracketed integer is appended, the vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the array calculated by the compute is used. Users can also write code for their own compute styles and `add them to LAMMPS`. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. Fixes can generate per-atom or local quantities. See the individual `fix` doc page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute reduce references the values, else an error results. If no bracketed integer is appended, the vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the array calculated by the fix is used. Users can also write code for their own fix style and `add them to LAMMPS`. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. It must be an `atom-style variable`. Atom-style variables can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to reduce.

If the `replace` keyword is used, two indices `vec1` and `vec2` are specified, where each index ranges from 1 to the # of input values. The replace keyword can only be used if the `mode` is `min` or `max`. It works as follows. A min/max is computed as usual on the `vec2` input vector. The index N of that value within `vec2` is also stored. Then, instead of performing a min/max on the `vec1` input vector, the stored index is used to select the Nth element of the `vec1` vector.

Thus, for example, if you wish to use this compute to find the bond with maximum stretch, you can do it as follows:

```
compute 1 all property/local batom1 batom2
compute 2 all bond/local dist
compute 3 all reduce max c_1[1] c_1[2] c_2 replace 1 3 replace 2 3
```

The first two input values in the compute reduce command are vectors with the IDs of the 2 atoms in each bond, using the `compute property/local` command. The last input value is bond distance, using the `compute bond/local` command. Instead of taking the max of the two atom ID vectors, which does not yield useful information in this context, the `replace` keywords will extract the atom IDs for the two atoms in the bond of maximum stretch. These atom IDs and the bond stretch will be printed with thermodynamic output.

If a single input is specified this compute produces a global scalar value. If multiple inputs are specified, this compute produces a global vector of values, the length of which is equal to the number of inputs specified.

As discussed below, for the `sum` and `sumsq` modes, the value(s) produced by this compute are all “extensive”, meaning their value scales linearly with the number of atoms involved. If normalized values are desired, this compute can be
accessed by the `thermo_style custom` command with `thermo_modify norm yes` set as an option. Or it can be accessed by a `variable` that divides by the appropriate atom count.

---

**19.77.4 Output info**

This compute calculates a global scalar if a single input value is specified or a global vector of length N where N is the number of inputs, and which can be accessed by indices 1 to N. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

All the scalar or vector values calculated by this compute are “intensive”, except when the `sum` or `sumsq` modes are used on per-atom or local vectors, in which case the calculated values are “extensive”.

The scalar or vector values will be in whatever *units* the quantities being reduced are in.

**19.78 compute reduce/chunk command**

**19.78.1 Syntax**

```
compute ID group-ID reduce/chunk chunkID mode input1 input2 ...
```

- ID, group-ID are documented in `compute` command
- reduce/chunk = style name of this compute command
- chunkID = ID of `compute chunk/atom` command
- mode = `sum` or `min` or `max`
- one or more inputs can be listed
- input = `c_ID, c_ID[N], f_ID, f_ID[N], v_ID`

`c_ID =` per-atom vector calculated by a compute with ID

`c_ID[I] =` Ith column of per-atom array calculated by a compute with ID, I can

`→include wildcard (see below)`

`f_ID =` per-atom vector calculated by a fix with ID

(continues on next page)
19.78.2 Examples

```
compute 1 all reduce/chunk/atom mychunk min c_cluster
```

19.78.3 Description

Define a calculation that reduces one or more per-atom vectors into per-chunk values. This can be useful for diagnostic output. Or when used in conjunction with the compute chunk/spread/atom command it can be used to create per-atom values that induce a new set of chunks with a second compute chunk/atom command. An example is given below.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and Howto chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

For each atom, this compute accesses its chunk ID from the specified chunkID compute. The per-atom value from an input contributes to a per-chunk value corresponding the the chunk ID.

The reduction operation is specified by the mode setting and is performed over all the per-atom values from the atoms in each chunk. The sum option adds the pre-atom values to a per-chunk total. The min or max options find the minimum or maximum value of the per-atom values for each chunk.

Note that only atoms in the specified group contribute to the reduction operation. If the chunkID compute returns a 0 for the chunk ID of an atom (i.e. the atom is not in a chunk defined by the compute chunk/atom command), that atom will also not contribute to the reduction operation. An input that is a compute or fix may define its own group which affects the quantities it returns. For example, a compute with return a zero value for atoms that are not in the group specified for that compute.

Each listed input is operated on independently. Each input can be the result of a compute or fix or the evaluation of an atom-style variable.

Note that for values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the size of the vector (for mode = scalar) or the number of columns in the array (for mode = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 compute reduce/chunk commands are equivalent, since the compute property/chunk command creates a per-atom array with 3 columns:

```
compute prop all property/atom vx vy vz
compute 10 all reduce/chunk mychunk max c_prop[*]
```

Here is an example of using this compute, in conjunction with the compute chunk/spread/atom command to identify self-assembled micelles. The commands below can be added to the examples/in.micelle script.
Imagine a collection of polymer chains or small molecules with hydrophobic end groups. All the hydrophobic (HP) atoms are assigned to a group called “phobic”.

These commands will assign a unique cluster ID to all HP atoms within a specified distance of each other. A cluster will contain all HP atoms in a single molecule, but also the HP atoms in nearby molecules, e.g. molecules that have clumped to form a micelle due to the attraction induced by the hydrophobicity. The output of the chunk/reduce command will be a cluster ID per chunk (molecule). Molecules with the same cluster ID are in the same micelle.

```plaintext
group phobic type 4  # specific to in.micelle model
compute cluster phobic cluster/atom 2.0
compute cmol all chunk/atom molecule
compute reduce phobic reduce/chunk cmol min c_cluster
```

This per-chunk info could be output in at least two ways:

```plaintext
fix 10 all ave/time 1000 1 1000 c_reduce file tmp.phobic mode vector
compute spread all chunk/spread/atom cmol c_reduce
dump 1 all custom 1000 tmp.dump id type mol x y z c_cluster c_spread
dump_modify 1 sort id
```

In the first case, each snapshot in the tmp.phobic file will contain one line per molecule. Molecules with the same value are in the same micelle. In the second case each dump snapshot contains all atoms, each with a final field with the cluster ID of the micelle that the HP atoms of that atom’s molecule belong to.

The result from compute chunk/spread/atom can be used to define a new set of chunks, where all the atoms in all the molecules in the same micelle are assigned to the same chunk, i.e. one chunk per micelle.

```plaintext
compute micelle all chunk/atom c_spread compress yes
```

Further analysis on a per-micelle basis can now be performed using any of the per-chunk computes listed on the Howto chunk doc page. E.g. count the number of atoms in each micelle, calculate its center or mass, shape (moments of inertia), radius of gyration, etc.

```plaintext
compute prop all property/chunk micelle count
fix 20 all ave/time 1000 1 1000 c_prop file tmp.micelle mode vector
```

Each snapshot in the tmp.micelle file will have one line per micelle with its count of atoms, plus a first line for a chunk with all the solvent atoms. By the time 50000 steps have elapsed there are a handful of large micelles.

### 19.78.4 Output info

This compute calculates a global vector if a single input value is specified, otherwise a global array is output. The number of columns in the array is the number of inputs provided. The length of the vector or the number of vector elements or array rows = the number of chunks $N_{\text{chunk}}$ as calculated by the specified compute chunk/atom command. The vector or array can be accessed by any command that uses global values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom values for the vector or each column of the array will be in whatever units the corresponding input value is in. The vector or array values are “intensive”.

19.79.2 Examples

\texttt{compute 1 all rigid/local myRigid mol x y z}

19.79.3 Description

Define a computation that simply stores rigid body attributes for rigid bodies defined by the \texttt{fix rigid/small} command or one of its NVE, NVT, NPT, NPH variants. The data is stored as local data so it can be accessed by other \texttt{output commands} that process local data, such as the \texttt{compute reduce} or \texttt{dump local} commands.

Note that this command only works with the \texttt{fix rigid/small} command or its variants, not the \texttt{fix rigid} command and its variants. The ID of the \texttt{fix rigid/small} command used to define rigid bodies must be specified as \texttt{rigidID}. The \texttt{fix rigid} command is typically used to define a handful of (potentially very large) rigid bodies. It outputs similar per-body information as this command directly from the fix as global data; see the \texttt{fix rigid} doc page for details.

The local data stored by this command is generated by looping over all the atoms owned on a processor. If the atom is not in the specified \texttt{group-ID} or is not part of a rigid body it is skipped. If it is not the atom within a body that is assigned to store the body information it is skipped (only one atom per body is so assigned). If it is the assigned atom, then the info for that body is output. This means that information for \texttt{N} bodies is generated. \texttt{N} may be less than the \# of bodies defined by the \texttt{fix rigid} command, if the atoms in some bodies are not in the \texttt{group-ID}.

Note: Which atom in a body owns the body info is determined internal to LAMMPS; it’s the one nearest the geometric center of the body. Typically you should avoid this complication, by defining the group associated with this fix to include/exclude entire bodies.

Note that as atoms and bodies migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next.

Here is an example of how to use this compute to dump rigid body info to a file:

\texttt{compute 1 all rigid/local myRigid mol x y z fx fy fz}

This section explains the rigid body attributes that can be specified.

The \texttt{id} attribute is the atom-ID of the atom which owns the rigid body, which is assigned by the \texttt{fix rigid/small} command.

The \texttt{mol} attribute is the molecule ID of the rigid body. It should be the molecule ID which all of the atoms in the body belong to, since that is how the \texttt{fix rigid/small} command defines its rigid bodies.

The \texttt{mass} attribute is the total mass of the rigid body.

There are two options for outputting the coordinates of the center of mass (COM) of the body. The \texttt{x, y, z} attributes write the COM “unscaled”, in the appropriate distance \texttt{units} (Angstroms, sigma, etc). Use \texttt{xu, yu, zu} if you want the COM “unwrapped” by the image flags for each body. Unwrapped means that if the body COM has passed through a periodic boundary one or more times, the value is generated what the COM coordinate would be if it had not been wrapped back into the periodic box.

The image flags for the body can be generated directly using the \texttt{ix, iy, iz} attributes. For periodic dimensions, they specify which image of the simulation box the COM is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as the rigid body COMs cross periodic boundaries during the simulation.

The \texttt{vx, vy, vz, fx, fy, fz} attributes are components of the COM velocity and force on the COM of the body.
The \textit{omegax}, \textit{omegay}, and \textit{omegaz} attributes are the angular velocity components of the body around its COM.

The \textit{angmomx}, \textit{angmomy}, and \textit{angmomz} attributes are the angular momentum components of the body around its COM.

The \textit{quatw}, \textit{quati}, \textit{quatj}, and \textit{quatk} attributes are the components of the 4-vector quaternion representing the orientation of the rigid body. See the \texttt{set} command for an explanation of the quaternion vector.

The \textit{angmomx}, \textit{angmomy}, and \textit{angmomz} attributes are the angular momentum components of the body around its COM.

The \textit{tqx}, \textit{tqy}, \textit{tqz} attributes are components of the torque acting on the body around its COM.

The \textit{inertiax}, \textit{inertiay}, \textit{inertiaz} attributes are components of diagonalized inertia tensor for the body, i.e the 3 moments of inertia for the body around its principal axes, as computed internally by LAMMPS.

\section*{19.79.4 Output info}

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of rigid bodies. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords.

The vector or array can be accessed by any command that uses local values from a compute as input. See the \texttt{Howto output} doc page for an overview of LAMMPS output options.

The vector or array values will be in whatever \textit{units} the corresponding attribute is in:

- \textit{id,mol} = unitless
- \textit{mass} = mass units
- \textit{x,y,z} and \textit{xy,yu,zu} = distance units
- \textit{vx,vy,vz} = velocity units
- \textit{fx,fy,fz} = force units
- \textit{omegax,omegay,omegaz} = radians/time units
- \textit{angmomx,angmomy,angmomz} = mass*distance^2/time units
- \textit{quatw,quati,quatj,quatk} = unitless
- \textit{tqx,tqy,tqz} = torque units
- \textit{inertiax,inertiay,inertiaz} = mass*distance^2 units

\section*{19.79.5 Restrictions}

This compute is part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the \texttt{Build package} doc page for more info.

fix saed/vtk 1 1 1 c_1 file A12O3_001.saed
fix saed/vtk 1 1 1 c_2 file Ni_000.saed
19.80.3 Description

Define a computation that calculates electron diffraction intensity as described in (Coleman) on a mesh of reciprocal lattice nodes defined by the entire simulation domain (or manually) using simulated radiation of wavelength lambda.

The electron diffraction intensity I at each reciprocal lattice point is computed from the structure factor F using the equations:

\[ I = \frac{F^*F}{N} \]

\[ F(k) = \sum_{j=1}^{N} f_j(\theta) \exp(2\pi i k \cdot r_j) \]

Here, K is the location of the reciprocal lattice node, \( r_j \) is the position of each atom, \( f_j \) are atomic scattering factors.

Diffraction intensities are calculated on a three-dimensional mesh of reciprocal lattice nodes. The mesh spacing is defined either (a) by the entire simulation domain or (b) manually using selected values as shown in the 2D diagram below.

For a mesh defined by the simulation domain, a rectilinear grid is constructed with spacing \( c*\text{inv}(A) \) along each reciprocal lattice axis. Where A are the vectors corresponding to the edges of the simulation cell. If one or two directions has non-periodic boundary conditions, then the spacing in these directions is defined from the average of the (inversed) box lengths with periodic boundary conditions. Meshes defined by the simulation domain must contain at least one periodic boundary.

If the manual flag is included, the mesh of reciprocal lattice nodes will defined using the \( c \) values for the spacing along each reciprocal lattice axis. Note that manual mapping of the reciprocal space mesh is good for comparing diffraction results from multiple simulations; however it can reduce the likelihood that Bragg reflections will be satisfied unless small spacing parameters <0.05 Angstrom^-1 are implemented. Meshes with manual spacing do not require a periodic boundary.

The limits of the reciprocal lattice mesh are determined by the use of the \( K_{\text{max}}, Zone, \) and \( d_{R_{Ewald}} \) parameters. The rectilinear mesh created about the origin of reciprocal space is terminated at the boundary of a sphere of radius \( K_{\text{max}} \) centered at the origin. If \( Zone \) parameters \( z1=z2=z3=0 \) are used, diffraction intensities are computed throughout the entire spherical volume - note this can greatly increase the cost of computation. Otherwise, \( Zone \) parameters will denote the \( z1=h, z2=k, \) and \( z3=l \) (in a global since) zone axis of an intersecting Ewald sphere. Diffraction intensities will only be computed at the intersection of the reciprocal lattice mesh and a \( d_{R_{Ewald}} \) thick surface of the Ewald sphere. See the example 3D intensity data and the intersection of a [010] zone axis in the below image.
The atomic scattering factors, \( f_j \), accounts for the reduction in diffraction intensity due to Compton scattering. Compute saed uses analytical approximations of the atomic scattering factors that vary for each atom type (type1 type2 ... typeN) and angle of diffraction. The analytic approximation is computed using the formula (Brown):

\[
f_j \left( \frac{\sin(\theta)}{\lambda} \right) = \sum_{i} a_{i, \exp} \left( -b_i \frac{\sin^2(\theta)}{\lambda^2} \right)
\]

Coefficients parameterized by (Fox) are assigned for each atom type designating the chemical symbol and charge of each atom type. Valid chemical symbols for compute saed are:

| H | He | Li | Be | B | C | N | O | F | Ne | Na | Mg | Al | Si | P | S | Cl | Ar | K | Ca |

If the `echo` keyword is specified, compute saed will provide extra reporting information to the screen.
19.80.4 Output info

This compute calculates a global vector. The length of the vector is the number of reciprocal lattice nodes that are explored by the mesh. The entries of the global vector are the computed diffraction intensities as described above.

The vector can be accessed by any command that uses global values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

All array values calculated by this compute are “intensive”.

19.80.5 Restrictions

This compute is part of the USER-DIFFRACTION package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

The compute_saed command does not work for triclinic cells.

19.80.6 Related commands

*fix saed_vtk, compute xrd*

19.80.7 Default

The option defaults are Kmax = 1.70, Zone 1 0 0, c 1 1 1, dR_Ewald = 0.01.

(Coleman) Coleman, Spearot, Capolungo, MSMSE, 21, 055020 (2013).

19.81 compute slice command

19.81.1 Syntax

```
compute ID group-ID slice Nstart Nstop Nskip input1 input2 ...
```

- ID, group-ID are documented in *compute* command
- slice = style name of this compute command
- Nstart = starting index within input vector(s)
- Nstop = stopping index within input vector(s)
- Nskip = extract every Nskip elements from input vector(s)
- input = c_ID, c_ID[N], f_ID, f_ID[N]
**LAMMPS Documentation**

\[
\begin{align*}
\text{c_ID} &= \text{global vector calculated by a compute with ID} \\
\text{c_ID}[I] &= I\text{th column of global array calculated by a compute with ID} \\
\text{f_ID} &= \text{global vector calculated by a fix with ID} \\
\text{f_ID}[I] &= I\text{th column of global array calculated by a fix with ID} \\
\text{v_name} &= \text{vector calculated by an vector-style variable with name}
\end{align*}
\]

### 19.81.2 Examples

```plaintext
compute 1 all slice 1 100 10 c_msdmol[4]
compute 1 all slice 301 400 1 c_msdmol[4] v_myVec
```

### 19.81.3 Description

Define a calculation that “slices” one or more vector inputs into smaller vectors, one per listed input. The inputs can be global quantities; they cannot be per-atom or local quantities. Computes and fixes and vector-style variables can generate such global quantities. The group specified with this command is ignored.

The values extracted from the input vector(s) are determined by the \(N_{\text{start}}, N_{\text{stop}},\) and \(N_{\text{skip}}\) parameters. The elements of an input vector of length \(N\) are indexed from 1 to \(N\). Starting at element \(N_{\text{start}}\), every \(M\)th element is extracted, where \(M = N_{\text{skip}}\), until element \(N_{\text{stop}}\) is reached. The extracted quantities are stored as a vector, which is typically shorter than the input vector.

Each listed input is operated on independently to produce one output vector. Each listed input must be a global vector or column of a global array calculated by another compute or fix.

If an input value begins with “c_”, a compute ID must follow which has been previously defined in the input script and which generates a global vector or array. See the individual compute doc page for details. If no bracketed integer is appended, the vector calculated by the compute is used. If a bracketed integer is appended, the \(I\)th column of the array calculated by the compute is used. Users can also write code for their own compute styles and add them to LAMMPS.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script and which generates a global vector or array. See the individual fix doc page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute slice references the values, else an error results. If no bracketed integer is appended, the vector calculated by the fix is used. If a bracketed integer is appended, the \(I\)th column of the array calculated by the fix is used. Users can also write code for their own fix style and add them to LAMMPS.

If an input value begins with “v_”, a variable name must follow which has been previously defined in the input script. Only vector-style variables can be referenced. See the variable command for details. Note that variables of style vector define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to slice.

If a single input is specified this compute produces a global vector, even if the length of the vector is 1. If multiple inputs are specified, then a global array of values is produced, with the number of columns equal to the number of inputs specified.
19.81.4 Output info

This compute calculates a global vector if a single input value is specified or a global array with N columns where N is the number of inputs. The length of the vector or the number of rows in the array is equal to the number of values extracted from each input vector. These values can be used by any command that uses global vector or array values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The vector or array values calculated by this compute are simply copies of values generated by computes or fixes or variables that are input vectors to this compute. If there is a single input vector of intensive and/or extensive values, then each value in the vector of values calculated by this compute will be “intensive” or “extensive”, depending on the corresponding input value. If there are multiple input vectors, and all the values in them are intensive, then the array values calculated by this compute are “intensive”. If there are multiple input vectors, and any value in them is extensive, then the array values calculated by this compute are “extensive”. Values produced by a variable are treated as intensive.

The vector or array values will be in whatever *units* the input quantities are in.

19.82 compute smd/contact/radius command

19.82.1 Syntax

```
compute ID group-ID smd/contact/radius
```

- **ID**, **group-ID** are documented in *compute* command
- **smd/contact/radius** = style name of this compute command

19.82.2 Examples

```
compute 1 all smd/contact/radius
```
19.82.3 Description

Define a computation which outputs the contact radius, i.e., the radius used to prevent particles from penetrating each other. The contact radius is used only to prevent particles belonging to different physical bodies from penetrating each other. It is used by the contact pair styles, e.g., smd/hertz and smd/tri_surface.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

The value of the contact radius will be 0.0 for particles not in the specified compute group.

19.82.4 Output info

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-particle vector values will be in distance units.

19.82.5 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.82.6 Related commands

dump custom smd/hertz smd/tri_surface

19.83 compute smd/damage command

19.83.1 Syntax

```
compute ID group-ID smd/damage
```

- ID, group-ID are documented in compute command
- smd/damage = style name of this compute command
19.83.2 Examples

```
compute 1 all smd/damage
```

19.83.3 Description

Define a computation that calculates the damage status of SPH particles according to the damage model which is defined via the SMD SPH pair styles, e.g., the maximum plastic strain failure criterion.

See this PDF guide to use Smooth Mach Dynamics in LAMMPS.

Output Info:

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-particle values are dimensionless and in the range of zero to one.

19.83.4 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the “Build

- smd/hourglass/error = style name of this compute command
19.84.2 Examples

```
compute 1 all smd/hourglass/error
```

19.84.3 Description

Define a computation which outputs the error of the approximated relative separation with respect to the actual relative separation of the particles i and j. Ideally, if the deformation gradient is exact, and there exists a unique mapping between all particles’ positions within the neighborhood of the central node and the deformation gradient, the approximated relative separation will coincide with the actual relative separation of the particles i and j in the deformed configuration. This compute is only really useful for debugging the hourglass control mechanism which is part of the Total-Lagrangian SPH pair style.

See this PDF guide to use Smooth Mach Dynamics in LAMMPS.

Output Info:

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-particle vector values will are dimensionless. See units.

19.84.4 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This quantity will be computed only for particles which interact with tlsph pair style.

- smd/tlsph/defgrad = style name of this compute command
19.89.2 Examples

```bash
compute 1 all smd/tlsph/defgrad
```

19.89.3 Description

Define a computation that calculates the deformation gradient. It is only meaningful for particles which interact according to the Total-Lagrangian SPH pair style.

See this PDF guide to use Smooth Mach Dynamics in LAMMPS.

19.89.4 Output info

This compute outputs a per-particle vector of vectors (tensors), which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-particle vector values will be given dimensionless. See units. The per-particle vector has 10 entries. The first nine entries correspond to the xx, xy, xz, yx, yy, yz, zx, zy, zz components of the asymmetric deformation gradient tensor. The tenth entry is the determinant of the deformation gradient.

19.89.5 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info. This compute can only be used for particles which interact via the total Lagrangian SPH pair style.

- smd/tlsph/dt = style name of this compute command
19.90.2 Examples

```plaintext
compute l all smd/tlsph/dt
```

19.90.3 Description

Define a computation that outputs the CFL-stable time increment per particle. This time increment is essentially given by the speed of sound, divided by the SPH smoothing length. Because both the speed of sound and the smoothing length typically change during the course of a simulation, the stable time increment needs to be re-computed every time step. This calculation is performed automatically in the relevant SPH pair styles and this compute only serves to make the stable time increment accessible for output purposes.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

19.90.4 Output info

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-particle values will be given in units of time.

19.90.5 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This compute can only be used for particles interacting with the Total-Lagrangian SPH pair style.

19.92.2 Examples

```
compute 1 all smd/tlsph/shape
```

19.92.3 Description

Define a computation that outputs the current shape of the volume associated with a particle as a rotated ellipsoid. It is only meaningful for particles which interact according to the Total-Lagrangian SPH pair style.

See this PDF guide to use Smooth Mach Dynamics in LAMMPS.

19.92.4 Output info

This compute calculates a per-particle vector of vectors, which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-particle vector has 7 entries. The first three entries correspond to the lengths of the ellipsoid’s axes and have units of length. These axis values are computed as the contact radius times the xx, yy, or zz components of the Green-Lagrange strain tensor associated with the particle. The next 4 values are quaternions (order: q, x, y, z) which describe the spatial rotation of the particle relative to its initial state.

19.92.5 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This quantity will be computed only for particles which interact with the Total-Lagrangian SPH pair style.

19.95.2 Examples

```
compute 1 all smd/tlsph/stress
```

19.95.3 Description

Define a computation that outputs the Cauchy stress tensor for particles interacting via the Total-Lagrangian SPH pair style.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

19.95.4 Output info

This compute calculates a per-particle vector of vectors (tensors), which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The values will be given in units of pressure.

The per-particle vector has 7 entries. The first six entries correspond to the xx, yy, zz, xy, xz and yz components of the symmetric Cauchy stress tensor. The seventh entry is the second invariant of the stress tensor, i.e., the von Mises equivalent stress.

19.95.5 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This quantity will be computed only for particles which interact with the Total-Lagrangian SPH pair style.

- smd/triangle/vertices = style name of this compute command
19.96.2 Examples

```
compute 1 all smd/triangle/mesh/vertices
```

19.96.3 Description

Define a computation that returns the coordinates of the vertices corresponding to the triangle-elements of a mesh created by the `fix smd/wall_surface`.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

19.96.4 Output info

This compute returns a per-particle vector of vectors, which can be accessed by any command that uses per-particle values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The per-particle vector has nine entries, \((x_1/y_1/z_1), (x_2/y_2/z_2), \text{ and } (x_3/y_3/z_3)\) corresponding to the first, second, and third vertex of each triangle.

It is only meaningful to use this compute for a group of particles which is created via the `fix smd/wall_surface` command.

The output of this compute can be used with the dump2vtk_tris tool to generate a VTK representation of the smd/wall_surface mesh for visualization purposes.

The values will be given in units of distance.

19.96.5 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

```

19.98.3 Description

Define a computation that returns the number of neighbor particles inside of the smoothing kernel radius for particles interacting via the updated Lagrangian SPH pair style.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

19.98.4 Output info

This compute returns a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-particle values will be given dimensionless, see units.

19.98.5 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info. This compute can only be used for particles which interact with the updated Lagrangian SPH pair style.

19.98.6 Related commands

- `smd/ulsph/strain` = style name of this compute command
19.99.2 Examples

```compute 1 all smd/ulsph/strain```

19.99.3 Description

Define a computation that outputs the logarithmic strain tensor for particles interacting via the updated Lagrangian SPH pair style.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

19.99.4 Output info

This compute calculates a per-particle tensor, which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-particle vector has 6 entries, corresponding to the xx, yy, zz, xy, xz, yz components of the symmetric strain rate tensor.

The per-particle tensor values will be given dimensionless, see units.

19.99.5 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info. This compute can only be used for particles which interact with the updated Lagrangian SPH pair style.

19.101.2 Examples

compute 1 all smd/ulsph/stress

19.101.3 Description

Define a computation that outputs the Cauchy stress tensor.
See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

19.101.4 Output info

This compute calculates a per-particle vector of vectors (tensors), which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The values will be given in units of pressure.

The per-particle vector has 7 entries. The first six entries correspond to the xx, yy, zz, xy, xz, yz components of the symmetric Cauchy stress tensor. The seventh entry is the second invariant of the stress tensor, i.e., the von Mises equivalent stress.

19.101.5 Restrictions

This compute is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info. This compute can only be used for particles which interact with the updated Lagrangian SPH pair style.

```
19.106.3 Description

Define a computation that calculates a set of quantities related to the bispectrum components of the atoms in a group. These computes are used primarily for calculating the dependence of energy, force, and stress components on the linear coefficients in the *snap pair_style*, which is useful when training a SNAP potential to match target data.

Bispectrum components of an atom are order parameters characterizing the radial and angular distribution of neighbor atoms. The detailed mathematical definition is given in the paper by Thompson et al. (Thompson)

The position of a neighbor atom *i* relative to a central atom *i* is a point within the 3D ball of radius \( R_{ii'} = \text{rcutfac} (R_i + R_i') \)

Bartok et al. (Bartok), proposed mapping this 3D ball onto the 3-sphere, the surface of the unit ball in a four-dimensional space. The radial distance \( r \) within \( R_{ii'} \) is mapped on to a third polar angle \( \theta_0 \) defined by,

\[
\theta_0 = \frac{r \text{fac0} r - r_{\text{min}0}}{R_{ii'} - r_{\text{min}0} \pi}
\]

In this way, all possible neighbor positions are mapped on to a subset of the 3-sphere. Points south of the latitude \( \theta_0 = r \text{fac0} \pi \) are excluded.

The natural basis for functions on the 3-sphere is formed by the representatives of \( SU(2) \), the matrices \( U_{m,m'}^{j}(\theta, \phi, 0) \). These functions are better known as \( D_{m,m'}^{j} \), the elements of the Wigner \( D \)-matrices (Meremianin, Varshalovich, Mason) The density of neighbors on the 3-sphere can be written as a sum of Dirac-delta functions, one for each neighbor, weighted by species and radial distance. Expanding this density function as a generalized Fourier series in the basis functions, we can write each Fourier coefficient as

\[
u_{m,m'}^{j} = U_{m,m'}^{j}(0,0,0) + \sum_{r,ii'} f_c(r_{ii'}) \nu_{m,m'}^{j}(0,0,0) U_{m,m'}^{j}(\theta_0, \theta, \phi)
\]

The \( \nu_{m,m'}^{j} \) neighbor weights are dimensionless numbers that depend on \( \mu_{ii'} \), the SNAP element of atom *i*′, while the central atom is arbitrarily assigned a unit weight. The function \( f_c(r) \) ensures that the contribution of each neighbor atom goes smoothly to zero at \( R_{ii'} \):

\[f_c(r) = \frac{1}{2} (\cos(\pi \frac{r - r_{\text{min}0}}{R_{ii'} - r_{\text{min}0}}) + 1), r \leq R_{ii'}
\]

\[ = 0, r > R_{ii'}
\]

The expansion coefficients \( u_{m,m'}^{j} \) are complex-valued and they are not directly useful as descriptors, because they are not invariant under rotation of the polar coordinate frame. However, the following scalar triple products of expansion coefficients can be shown to be real-valued and invariant under rotation (Bartok).

\[
B_{j_1,j_2,j_3} = \sum_{m_1,m_1'} = -j_1 \sum_{m_2,m_2'} = -j_2 \sum_{m,m'} = -j \left( u_{m,m'}^{j} \right)^* H_{j_1 m_1 m_1', j_2 m_2 m_2'}^{j m m'} u_{m_1,m_1'}^{j_1} u_{m_2,m_2'}^{j_2}
\]

The constants \( H_{j_1 m_1 m_1', j_2 m_2 m_2'}^{j m m'} \) are coupling coefficients, analogous to Clebsch-Gordan coefficients for rotations on the 2-sphere. These invariants are the components of the bispectrum and these are the quantities calculated by the compute snad/atom. They characterize the strength of density correlations at three points on the 3-sphere. The \( j_2=0 \) subset form the power spectrum, which characterizes the correlations of two points. The lowest-order components describe the coarsest features of the density function, while higher-order components reflect finer detail. Each bispectrum component contains terms that depend on the positions of up to 4 atoms (3 neighbors and the central atom).

Compute snad/atom calculates the derivative of the bispectrum components summed separately for each LAMMPS atom type:

\[- \sum_{i \in L} \frac{\partial B_{j_1,j_2,j_3}}{\partial r_i} \]
The sum is over all atoms \(i'\) of atom type \(I\). For each atom \(i\), this compute evaluates the above expression for each direction, each atom type, and each bispectrum component. See section below on output for a detailed explanation.

Compute \textit{snav/atom} calculates the virial contribution due to the derivatives:

\[-r_i \otimes \sum_{i' \in I} \frac{\partial B_{i'j_1j_2j_3}}{\partial r_i} \]

Again, the sum is over all atoms \(i'\) of atom type \(I\). For each atom \(i\), this compute evaluates the above expression for each of the six virial components, each atom type, and each bispectrum component. See section below on output for a detailed explanation.

Compute \textit{snap} calculates a global array containing information related to all three of the above per-atom computes \textit{sna/atom}, \textit{snad/atom}, and \textit{snav/atom}. The first row of the array contains the summation of \textit{sna/atom} over all atoms, but broken out by type. The last six rows of the array contain the summation of \textit{snav/atom} over all atoms, broken out by type. In between these are \(3N\) rows containing the same values computed by \textit{snad/atom} (these are already summed over all atoms and broken out by type). The element in the last column of each row contains the potential energy, force, or stress, according to the row. These quantities correspond to the user-specified reference potential that must be subtracted from the target data when fitting SNAP. The potential energy calculation uses the built in compute \textit{thermo_pe}. The stress calculation uses a compute called \textit{snap_press} that is automatically created behind the scenes, according to the following command:

\begin{verbatim}
compute snap_press all pressure NULL virial
\end{verbatim}

See section below on output for a detailed explanation of the data layout in the global array.

The value of all bispectrum components will be zero for atoms not in the group. Neighbor atoms not in the group do not contribute to the bispectrum of atoms in the group.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

The argument \(rcutfac\) is a scale factor that controls the ratio of atomic radius to radial cutoff distance.

The argument \(rfac0\) and the optional keyword \(rmin0\) define the linear mapping from radial distance to polar angle \(\theta_0\) on the 3-sphere, given above.

The argument \(twojmax\) defines which bispectrum components are generated. See section below on output for a detailed explanation of the number of bispectrum components and the ordered in which they are listed.

The keyword \textit{switchflag} can be used to turn off the switching function \(f_c(r)\).

The keyword \textit{bzeroflag} determines whether or not \(B_0\), the bispectrum components of an atom with no neighbors, are subtracted from the calculated bispectrum components. This optional keyword normally only affects compute \textit{sna/atom}. However, when \textit{quadraticflag} is on, it also affects \textit{snad/atom} and \textit{snav/atom}.

The keyword \textit{quadraticflag} determines whether or not the quadratic combinations of bispectrum quantities are generated. These are formed by taking the outer product of the vector of bispectrum components with itself. See section below on output for a detailed explanation of the number of quadratic terms and the ordered in which they are listed.

The keyword \textit{chem} activates the explicit multi-element variant of the SNAP bispectrum components. The argument \textit{nelements} specifies the number of SNAP elements that will be handled. This is followed by \textit{elementlist}, a list of integers of length \(n\text{types}\), with values in the range \([0, \text{nelements})\), which maps each LAMMPS type to one of the SNAP elements. Note that multiple LAMMPS types can be mapped to the same element, and some elements may be mapped by no LAMMPS type. However, in typical use cases (training SNAP potentials) the mapping from LAMMPS types to elements is one-to-one.

The explicit multi-element variant invoked by the \textit{chem} keyword partitions the density of neighbors into partial densities for each chemical element. This is described in detail in the paper by Cusentino et al. The bispectrum components
are indexed on ordered triplets of elements:

\[ B_{j_1,j_2,j}^{\lambda \kappa \mu} = \sum_{m_1,m_1'=-j_1} j_1 \sum_{m_2,m_2'=-j_2} j_2 \sum_{m,m'=0}^{j} (u_{j,m,m'}^{\mu})^* H_{j_1 m_1 m_1'}^{j m m'} H_{j_2 m_2 m_2'}^{j m m'} u_{j_1 m_1 m_1'}^{\kappa} u_{j_2 m_2 m_2'}^{\lambda} \]

where \( u_{j,m,m'}^{\mu} \) is an expansion coefficient for the partial density of neighbors of element \( \mu \)

\[ u_{j,m,m'}^{\mu} = w_{\text{self}}^{\mu} f_{j,m,m'}^{(0,0,0)} + \sum_{r_{i,i'} R_{i,i'}} \delta_{\mu_{i,i'}} f_{c}^{(r_{i,i'})} w_{\mu_{i,i'}} U_{j,m,m'}^{j,m,m'}(\theta_0, \theta, \phi) \]

where \( w_{\text{self}}^{\mu} \) is the self-contribution, which is either 1 or 0 (see keyword \( \text{wselfallflag} \) below), \( \delta_{\mu_{i,i'}} \) indicates that the sum is only over neighbor atoms of element \( \mu \), and all other quantities are the same as those appearing in the original equation for \( u_{j,m,m'}^{\mu} \) given above.

The keyword \( \text{wselfallflag} \) defines the rule used for the self-contribution. If \( \text{wselfallflag} \) is on, then \( w_{\text{self}}^{\mu} = 1 \). If it is off then \( w_{\text{self}}^{\mu} = 0 \), except in the case of \( \mu_i = \mu \), when \( w_{\text{self}}^{\mu} = 1 \). When the \( \text{chem} \) keyword is not used, this keyword has no effect.

The keyword \( \text{bnormflag} \) determines whether or not the bispectrum component \( B_{j_1,j_2,j} \) is divided by a factor of \( 2j+1 \). This normalization simplifies force calculations because of the following symmetry relation

\[ \frac{B_{j_1,j_2,j}}{2j+1} = \frac{B_{j_2,j_1,j}}{2j_1+1} = \frac{B_{j_1,j_2,j}}{2j_2+1} \]

This option is typically used in conjunction with the \( \text{chem} \) keyword, and LAMMPS will generate a warning if both \( \text{chem} \) and \( \text{bnormflag} \) are not both set or not both unset.

Note: If you have a bonded system, then the settings of \( \text{special_bonds} \) command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the \( \text{special_bonds} \) command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the calculation. One way to get around this, is to write a dump file, and use the \( \text{rerun} \) command to compute the bispectrum components for snapshots in the dump file. The rerun script can use a \( \text{special_bonds} \) command that includes all pairs in the neighbor list.

19.106.4 Output info

Compute \( \text{sna/atom} \) calculates a per-atom array, each column corresponding to a particular bispectrum component. The total number of columns and the identity of the bispectrum component contained in each column depend of the value of \( \text{twojmax} \), as described by the following piece of python code:

```python
for j1 in range(0,twojmax+1):
    for j2 in range(0,j1+1):
        for j in range(j1-j2, min(twojmax, j1+j2)+1, 2):
            if (j>=j1): print j1/2., j2/2., j/2.
```

For even \( \text{twojmax} = 2(m-1) \), \( K = m(m+1)(2m+1)/6 \), the \( m \)-th pyramidal number. For odd \( \text{twojmax} = 2m-1 \), \( K = m(m+1)(m+2)/3 \), twice the \( m \)-th tetrahedral number.

Note: the \( \text{diagonal} \) keyword allowing other possible choices for the number of bispectrum components was removed in 2019, since all potentials use the value of 3, corresponding to the above set of bispectrum components.
Compute \textit{snad/atom} evaluates a per-atom array. The columns are arranged into \textit{ntypes} blocks, listed in order of atom type \textit{I}. Each block contains three sub-blocks corresponding to the \textit{x}, \textit{y}, and \textit{z} components of the atom position. Each of these sub-blocks contains \textit{K} columns for the \textit{K} bispectrum components, the same as for compute \textit{sna/atom}.

Compute \textit{snav/atom} evaluates a per-atom array. The columns are arranged into \textit{ntypes} blocks, listed in order of atom type \textit{I}. Each block contains six sub-blocks corresponding to the \textit{xx}, \textit{yy}, \textit{zz}, \textit{yz}, \textit{xz}, and \textit{xy} components of the virial tensor in Voigt notation. Each of these sub-blocks contains \textit{K} columns for the \textit{K} bispectrum components, the same as for compute \textit{sna/atom}.

Compute \textit{snap} evaluates a global array. The columns are arranged into \textit{ntypes} blocks, listed in order of atom type \textit{I}. Each block contains one column for each bispectrum component, the same as for compute \textit{sna/atom}. A final column contains the corresponding energy, force component on an atom, or virial stress component. The rows of the array appear in the following order:

- 1 row: \textit{sna/atom} quantities summed for all atoms of type \textit{I}
- 3*\textit{N} rows: \textit{snad/atom} quantities, with derivatives w.r.t. \textit{x}, \textit{y}, and \textit{z} coordinate of atom \textit{i} appearing in consecutive rows. The atoms are sorted based on atom ID.
- 6 rows: \textit{snav/atom} quantities summed for all atoms of type \textit{I}

For example, if \textit{K} = 30 and \textit{ntypes} = 1, the number of columns in the per-atom arrays generated by \textit{sna/atom}, \textit{snad/atom}, and \textit{snav/atom} are 30, 90, and 180, respectively. With \textit{quadratic} value = 1, the numbers of columns are 930, 2790, and 5580, respectively. The number of columns in the global array generated by \textit{snap} are 31, and 931, respectively, while the number of rows is 1+3*\textit{N}+6, where \textit{N} is the total number of atoms.

If the \textit{quadratic} keyword value is set to 1, then additional columns are generated, corresponding to the products of all distinct pairs of bispectrum components. If the number of bispectrum components is \textit{K}, then the number of distinct pairs is \textit{K}(\textit{K}+1)/2. For compute \textit{sna/atom} these columns are appended to existing \textit{K} columns. The ordering of quadratic terms is upper-triangular, (1,1),(1,2),..., (1,\textit{K}),(2,1),..., (\textit{K}-1,\textit{K}-1),(\textit{K}-1,\textit{K}),(\textit{K},\textit{K}). For computes \textit{snad/atom} and \textit{snav/atom} each set of \textit{K}(\textit{K}+1)/2 additional columns is inserted directly after each of sub-block of linear terms i.e. linear and quadratic terms are contiguous. So the nesting order from inside to outside is bispectrum component, linear then quadratic, vector/tensor component, type.

If the \textit{chem} keyword is used, then the data is arranged into \textit{N}_{\text{elem}}^3 sub-blocks, each sub-block corresponding to a particular chemical labeling \(\kappa\lambda\mu\) with the last label changing fastest. Each sub-block contains \textit{K} bispectrum components. For the purposes of handling contributions to force, virial, and quadratic combinations, these \textit{N}_{\text{elem}}^3 sub-blocks are treated as a single block of \(KN_{\text{elem}}^3\) columns.

These values can be accessed by any command that uses per-atom values from a compute as input. See the \textit{Howto output} doc page for an overview of LAMMPS output options. To see how this command can be used within a Python workflow to train SNAP potentials, see the examples in \textit{FitSNAP}.
19.106.5 Restrictions

These computes are part of the SNAP package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.107 compute sph/e/atom command

19.107.1 Syntax

```
compute ID group-ID sph/e/atom
```

- ID, group-ID are documented in compute command
- sph/e/atom = style name of this compute command

19.107.2 Examples

```
compute 1 all sph/e/atom
```
19.107.3 Description

Define a computation that calculates the per-atom internal energy for each atom in a group.

The internal energy is the energy associated with the internal degrees of freedom of an SPH particle, i.e. a Smooth-Particle Hydrodynamics particle.

See this PDF guide to using SPH in LAMMPS.

The value of the internal energy will be 0.0 for atoms not in the specified compute group.

19.107.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector values will be in energy units.

19.107.5 Restrictions

This compute is part of the USER-SPH package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

compute 1 all sph/rho/atom
```

19.108.3 Description

Define a computation that calculates the per-atom SPH density for each atom in a group, i.e. a Smooth-Particle Hydrodynamics density.

The SPH density is the mass density of an SPH particle, calculated by kernel function interpolation using “pair style sph/rhosum”.

See this PDF guide to using SPH in LAMMPS.

The value of the SPH density will be 0.0 for atoms not in the specified compute group.

19.108.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom vector values will be in mass/volume units.

19.108.5 Restrictions

This compute is part of the USER-SPH package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.109.3 Description

Define a computation that calculates the per-atom internal temperature for each atom in a group. The internal temperature is the ratio of internal energy over the heat capacity associated with the internal degrees of freedom of an SPH particles, i.e. a Smooth-Particle Hydrodynamics particle.

\[ T_{\text{int}} = \frac{E_{\text{int}}}{C_{V,\text{int}}} \]

See this PDF guide to using SPH in LAMMPS. The value of the internal energy will be 0.0 for atoms not in the specified compute group.

19.109.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options. The per-atom vector values will be in temperature units.

19.109.5 Restrictions

This compute is part of the USER-SPH package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.109.6 Related commands

\texttt{dump custom}

19.109.7 Default

none

19.110 compute spin command

19.110.1 Syntax

\texttt{compute ID group-ID spin}

- ID, group-ID are documented in compute command
- spin = style name of this compute command
19.110.2 Examples

\texttt{compute out\_mag all spin}

19.110.3 Description

Define a computation that calculates magnetic quantities for a system of atoms having spins.

This compute calculates the following 6 magnetic quantities:

- the three first quantities are the \(x\text{-}\), \(y\text{-}\) and \(z\text{-}\) coordinates of the total magnetization,
- the fourth quantity is the norm of the total magnetization,
- The fifth quantity is the magnetic energy (in eV),
- The sixth one is referred to as the spin temperature, according to the work of (Nurdin).

The simplest way to output the results of the compute spin calculation is to define some of the quantities as variables, and to use the thermo and thermo_style commands, for example:

\begin{verbatim}
compute out\_mag all spin
variable mag_z equal c_out_mag[3]
variable mag_norm equal c_out_mag[4]
variable temp_mag equal c_out_mag[6]
thermo 10
thermo_style custom step v_mag_z v_mag_norm v_temp_mag
\end{verbatim}

This series of commands evaluates the total magnetization along \(z\text{-}\), the norm of the total magnetization, and the magnetic temperature. Three variables are assigned to those quantities. The thermo and thermo_style commands print them every 10 timesteps.

19.110.4 Output info

The array values are “intensive”. The array values will be in metal units \textit{(units)}.

19.110.5 Restrictions

The spin compute is part of the SPIN package. This compute is only enabled if LAMMPS was built with this package. See the Build package doc page for more info. The atom_style has to be “spin” for this compute to be valid.

\]

- ID, group-ID are documented in compute command
- style = stress/atom or centroid/stress/atom
- temp-ID = ID of compute that calculates temperature, can be NULL if not needed
- zero or more keywords may be appended
- keyword = \textit{ke} or \textit{pair} or \textit{bond} or \textit{angle} or \textit{dihedral} or \textit{improper} or \textit{kspace} or \textit{fix} or \textit{virial}

19.112.2 Examples

\begin{verbatim}
compute 1 mobile stress/atom NULL
compute 1 mobile stress/atom myRamp
compute 1 all stress/atom NULL pair bond
compute 1 all centroid/stress/atom NULL bond dihedral improper
\end{verbatim}

19.112.3 Description

Define a computation that computes per-atom stress tensor for each atom in a group. In case of compute \textit{stress/atom}, the tensor for each atom is symmetric with 6 components and is stored as a 6-element vector in the following order: \textit{xx}, \textit{yy}, \textit{zz}, \textit{xy}, \textit{xz}, \textit{yz}. In case of compute \textit{centroid/stress/atom}, the tensor for each atom is asymmetric with 9 components and is stored as a 9-element vector in the following order: \textit{xx}, \textit{yy}, \textit{zz}, \textit{xy}, \textit{xz}, \textit{yz}, \textit{yx}, \textit{zx}, \textit{zy}. See the compute pressure command if you want the stress tensor (pressure) of the entire system.

The stress tensor for atom \textit{I} is given by the following formula, where \textit{a} and \textit{b} take on values \textit{x}, \textit{y}, \textit{z} to generate the components of the tensor:

\[
S_{ab} = -mv_av_b - W_{ab}
\]

The first term is a kinetic energy contribution for atom \textit{I}. See details below on how the specified \textit{temp-ID} can affect the velocities used in this calculation. The second term is the virial contribution due to intra and intermolecular interactions, where the exact computation details are determined by the compute style.
In case of compute stress/atom, the virial contribution is:

\[
W_{ab} = \frac{1}{2} \sum_{n=1}^{N_p} (r_{1a} F_{1b} + r_{2a} F_{2b}) + \frac{1}{2} \sum_{n=1}^{N_b} (r_{1a} F_{1b} + r_{2a} F_{2b}) \\
+ \frac{1}{3} \sum_{n=1}^{N_i} (r_{1a} F_{1b} + r_{2a} F_{2b} + r_{3a} F_{3b}) + \frac{1}{4} \sum_{n=1}^{N_d} (r_{1a} F_{1b} + r_{2a} F_{2b} + r_{3a} F_{3b} + r_{4a} F_{4b}) \\
+ \frac{1}{4} \sum_{n=1}^{N_f} (r_{1a} F_{1b} + r_{2a} F_{2b} + r_{3a} F_{3b} + r_{4a} F_{4b}) + K_{\text{space}}(r_{1a}, F_{1b}) + \sum_{n=1}^{N_f} r_{ia} F_{ib}
\]

The first term is a pairwise energy contribution where \( n \) loops over the \( N_p \) neighbors of atom \( I \), \( r_1 \) and \( r_2 \) are the positions of the 2 atoms in the pairwise interaction, and \( F_1 \) and \( F_2 \) are the forces on the 2 atoms resulting from the pairwise interaction. The second term is a bond contribution of similar form for the \( N_b \) bonds which atom \( I \) is part of. There are similar terms for the \( N_\alpha \) angle, \( N_d \) dihedral, and \( N_i \) improper interactions atom \( I \) is part of. There is also a term for the KSpace contribution from long-range Coulombic interactions, if defined. Finally, there is a term for the \( N_f \) fixes that apply internal constraint forces to atom \( I \). Currently, only the fix shake and fix rigid commands contribute to this term. As the coefficients in the formula imply, a virial contribution produced by a small set of atoms (e.g. 4 atoms in a dihedral or 3 atoms in a Tersoff 3-body interaction) is assigned in equal portions to each atom in the set. E.g. 1/4 of the dihedral virial to each of the 4 atoms, or 1/3 of the fix virial due to SHAKE constraints applied to atoms in a water molecule via the fix shake command.

In case of compute centroid/stress/atom, the virial contribution is:

\[
W_{ab} = \sum_{n=1}^{N_p} r_{10a} F_{1b} + \sum_{n=1}^{N_b} r_{10a} F_{1b} + \sum_{n=1}^{N_d} r_{10a} F_{1b} + \sum_{n=1}^{N_d} r_{10a} F_{1b} + \sum_{n=1}^{N_i} r_{10a} F_{1b} \\
+ K_{\text{space}}(r_{1a}, F_{1b}) + \sum_{n=1}^{N_f} r_{ia} F_{ib}
\]

As with compute stress/atom, the first, second, third, fourth and fifth terms are pairwise, bond, angle, dihedral and improper contributions, but instead of assigning the virial contribution equally to each atom, only the force \( F_I \) acting on atom \( I \) due to the interaction and the relative position \( r_{10} \) of the atom \( I \) to the geometric center of the interacting atoms, i.e. centroid, is used. As the geometric center is different for each interaction, the \( r_{10} \) also differs. The sixth and seventh terms, Kspace and fix contribution respectively, are computed identical to compute stress/atom. Although the total system virial is the same as compute stress/atom, compute centroid/stress/atom is know to result in more consistent heat flux values for angle, dihedrals and impropers when computed via compute heat/flux.

If no extra keywords are listed, the kinetic contribution all of the virial contribution terms are included in the per-atom stress tensor. If any extra keywords are listed, only those terms are summed to compute the tensor. The virial keyword means include all terms except the kinetic energy ke.

Note that the stress for each atom is due to its interaction with all other atoms in the simulation, not just with other atoms in the group.

Details of how compute stress/atom obtains the virial for individual atoms for either pairwise or many-body potentials, and including the effects of periodic boundary conditions is discussed in (Thompson). The basic idea for many-body potentials is to treat each component of the force computation between a small cluster of atoms in the same manner as in the formula above for bond, angle, dihedral, etc interactions. Namely the quantity \( r \cdot F \) is summed over the atoms in the interaction, with the \( r \) vectors unwrapped by periodic boundaries so that the cluster of atoms is close together. The total contribution for the cluster interaction is divided evenly among those atoms. Details of how compute centroid/stress/atom obtains the virial for individual atoms is given in (Surblys), where the idea is that the virial of the atom \( I \) is the result of only the force \( F_I \) on the atom due to the interaction and its positional vector \( r_{10} \), relative to the geometric center of the interacting atom, regardless of the number of participating atoms. The periodic boundary treatment is identical to that of compute stress/atom, and both of them reduce to identical expressions for two-body interactions, i.e. computed values for contributions from bonds and two-body pair styles, such as Lennard-Jones, will be the same, while contributions from angles, dihedrals and impropers will be different.
The \textit{dihedral_style charmmp} style calculates pairwise interactions between 1-4 atoms. The virial contribution of these terms is included in the pair virial, not the dihedral virial.

The KSpace contribution is calculated using the method in \textit{(Heyes)} for the Ewald method and by the methodology described in \textit{(Sirk)} for PPPM. The choice of KSpace solver is specified by the \textit{kspace_style ppm} command. Note that for PPPM, the calculation requires 6 extra FFTs each timestep that per-atom stress is calculated. Thus it can significantly increase the cost of the PPPM calculation if it is needed on a large fraction of the simulation timesteps.

The \textit{temp-ID} argument can be used to affect the per-atom velocities used in the kinetic energy contribution to the total stress. If the kinetic energy is not included in the stress, than the temperature compute is not used and can be specified as NULL. If the kinetic energy is included and you wish to use atom velocities as-is, then \textit{temp-ID} can also be specified as NULL. If desired, the specified temperature compute can be one that subtracts off a bias to leave each atom with only a thermal velocity to use in the formula above, e.g. by subtracting a background streaming velocity. See the doc pages for individual compute commands to determine which ones include a bias.

Note that as defined in the formula, per-atom stress is the negative of the per-atom pressure tensor. It is also really a stress*volume formulation, meaning the computed quantity is in units of pressure*volume. It would need to be divided by a per-atom volume to have units of stress (pressure), but an individual atom’s volume is not well defined or easy to compute in a deformed solid or a liquid. See the \textit{compute voronoi/atom} command for one possible way to estimate a per-atom volume.

Thus, if the diagonal components of the per-atom stress tensor are summed for all atoms in the system and the sum is divided by \(dV\), where \(d\) = dimension and \(V\) is the volume of the system, the result should be \(-P\), where \(P\) is the total pressure of the system.

These lines in an input script for a 3d system should yield that result. I.e. the last 2 columns of thermo output will be the same:

\begin{verbatim}
compute peratom all stress/atom NULL
thermo_style custom step temp etotal press v_press
\end{verbatim}

Note: The per-atom stress does not include any Lennard-Jones tail corrections to the pressure added by the \textit{pair_modify tail yes} command, since those are contributions to the global system pressure.

\subsection{19.112.4 Output info}

This compute \textit{stress/atom} calculates a per-atom array with 6 columns, which can be accessed by indices 1-6 by any command that uses per-atom values from a compute as input. The compute \textit{centroid/stress/atom} produces a per-atom array with 9 columns, but otherwise can be used in an identical manner to compute \textit{stress/atom}. See the \textit{Howto output} doc page for an overview of LAMMPS output options.

The per-atom array values will be in pressure*volume \textit{units} as discussed above.
19.112.5 Restrictions

Currently (Spring 2020), compute `centroid/stress/atom` does not support pair styles with many-body interactions, such as `Tersoff`, or pair styles with long-range Coulomb interactions. LAMMPS will generate an error in such cases. In principal, equivalent formulation to that of angle, dihedral and improper contributions in the virial $W_{ab}$ formula can also be applied to the many-body pair styles, and is planned in the future.

fix 1 all ave/time 10 1000 10000 c_1[2] file mop.time

19.114.2 Description

Compute `stress/mop` and compute `stress/mop/profile` define computations that calculate components of the local stress tensor using the method of planes (Todd). Specifically in `compute stress/mop` calculates 3 components are computed in directions `dir,x`, `dir,y`, and `dir,z`; where `dir` is the direction normal to the plane, while in `compute stress/mop/profile` the profile of the stress is computed.

Contrary to methods based on histograms of atomic stress (i.e. using `compute stress/atom`), the method of planes is compatible with mechanical balance in heterogeneous systems and at interfaces (Todd).

The stress tensor is the sum of a kinetic term and a configurational term, which are given respectively by Eq. (21) and Eq. (16) in (Todd). For the kinetic part, the algorithm considers that atoms have crossed the plane if their positions at times `t-dt` and `t` are on either side of the plane, and uses the velocity at time `t-dt/2` given by the velocity-Verlet algorithm.

Between one and three keywords can be used to indicate which contributions to the stress must be computed: kinetic stress (kin), configurational stress (conf), and/or total stress (total).

NOTE 1: The configurational stress is computed considering all pairs of atoms where at least one atom belongs to group group-ID.

NOTE 2: The local stress does not include any Lennard-Jones tail corrections to the pressure added by the `pair_modify tail yes` command, since those are contributions to the global system pressure.

19.114.3 Output info

Compute `stress/mop` calculates a global vector (indices starting at 1), with 3 values for each declared keyword (in the order the keywords have been declared). For each keyword, the stress tensor components are ordered as follows: stress_dir,x, stress_dir,y, and stress_dir,z.

Compute `stress/mop/profile` instead calculates a global array, with 1 column giving the position of the planes where the stress tensor was computed, and with 3 columns of values for each declared keyword (in the order the keywords have been declared). For each keyword, the profiles of stress tensor components are ordered as follows: stress_dir,x; stress_dir,y; and stress_dir,z.

The values are in pressure units.

The values produced by this compute can be accessed by various output commands. For instance, the results can be written to a file using the `fix ave/time` command. Please see the example in the examples/USER/mop folder.
19.114.4 Restrictions

These styles are part of the USER-MISC package. They are only enabled if LAMMPS is built with that package. See the Build package doc page on for more info.

The method is only implemented for 3d orthogonal simulation boxes whose size does not change in time, and axis-aligned planes.

The method only works with two-body pair interactions, because it requires the class method pair->single() to be implemented. In particular, it does not work with more than two-body pair interactions, intra-molecular interactions, and long range (kspace) interactions.

compute ID group-ID style group2-ID
```

- ID, group-ID are documented in compute command
- style = force/tally or pe/tally or pe/mol/tally or stress/tally
- group2-ID = group ID of second (or same) group
19.119.2 Examples

```plaintext
compute 1 lower force/tally upper
compute 1 left pe/tally right
compute 1 lower stress/tally lower
```

19.119.3 Description

Define a computation that calculates properties between two groups of atoms by accumulating them from pairwise non-bonded computations. The two groups can be the same. This is similar to `compute group/group` only that the data is accumulated directly during the non-bonded force computation. The computes `force/tally`, `pe/tally`, `stress/tally`, and `heat/flux/tally` are primarily provided as example how to program additional, more sophisticated computes using the tally callback mechanism. Compute `pe/mol/tally` is one such style, that can - through using this mechanism - separately tally intermolecular and intramolecular energies. Something that would otherwise be impossible without integrating this as a core functionality into the based classes of LAMMPS.

The pairwise contributions are computing via a callback that the compute registers with the non-bonded pairwise force computation. This limits the use to systems that have no bonds, no Kspace, and no many-body interactions. On the other hand, the computation does not have to compute forces or energies a second time and thus can be much more efficient. The callback mechanism allows to write more complex pairwise property computations.

19.119.4 Output info

Compute `pe/tally` calculates a global scalar (the energy) and a per atom scalar (the contributions of the single atom to the global scalar). Compute `pe/mol/tally` calculates a global 4-element vector containing (in this order): `evdwl` and `ecoul` for intramolecular pairs and `evdwl` and `ecoul` for intermolecular pairs. Since molecules are identified by their molecule IDs, the partitioning does not have to be related to molecules, but the energies are tallied into the respective slots depending on whether the molecule IDs of a pair are the same or different. Compute `force/tally` calculates a global scalar (the force magnitude) and a per atom 3-element vector (force contribution from each atom). Compute `stress/tally` calculates a global scalar (average of the diagonal elements of the stress tensor) and a per atom vector (the 6 elements of stress tensor contributions from the individual atom).

Both the scalar and vector values calculated by this compute are “extensive”.

19.119.5 Restrictions

This compute is part of the USER-TALLY package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

Not all pair styles can be evaluated in a pairwise mode as required by this compute. For example, 3-body and other many-body potentials, such as `Tersoff` and `Stillinger-Weber` cannot be used. `EAM` potentials only include the pair potential portion of the EAM interaction when used by this compute, not the embedding term. Also bonded or Kspace interactions do not contribute to this compute.

The computes in this package are not compatible with dynamic groups.

19.121 compute temp command

Accelerator Variants: temp/kk

19.121.1 Syntax

compute ID group-ID temp

- ID, group-ID are documented in compute command
- temp = style name of this compute command

19.121.2 Examples

compute 1 all temp
compute myTemp mobile temp

19.121.3 Description

Define a computation that calculates the temperature of a group of atoms. A compute of this style can be used by any command that computes a temperature, e.g. thermo_modify, fix temp/rescale, fix npt, etc.

The temperature is calculated by the formula \( KE = \frac{\text{dim}}{2} N k T \), where \( KE = \) total kinetic energy of the group of atoms (sum of \( \frac{1}{2} m v^2 \)), \( \text{dim} = 2 \) or \( 3 \) = dimensionality of the simulation, \( N = \) number of atoms in the group, \( k = \) Boltzmann constant, and \( T = \) temperature.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( v_x v_y \) for the \( xy \) component, etc. The 6 components of the vector are ordered \( xx, yy, zz, xy, xz, yz \).

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the dynamic option of the compute_modify command if this is not the case.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as fix shake and fix rigid. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the extra option of the compute_modify command.

A compute of this style with the ID of “thermo_temp” is created when LAMMPS starts up, as if this command were in the input script:
compute thermo_temp all temp

See the “thermo_style” command for more details.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostatting.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

19.121.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

\end{align*}
\]

19.122.2 Examples

\begin{verbatim}
compute 1 all temp/asphere
compute myTemp mobile temp/asphere bias tempCOM
compute myTemp mobile temp/asphere dof rotate
\end{verbatim}

19.122.3 Description

Define a computation that calculates the temperature of a group of aspherical particles, including a contribution from both their translational and rotational kinetic energy. This differs from the usual \textit{compute temp} command, which assumes point particles with only translational kinetic energy.

Only finite-size particles (aspherical or spherical) can be included in the group. For 3d finite-size particles, each has 6 degrees of freedom (3 translational, 3 rotational). For 2d finite-size particles, each has 3 degrees of freedom (2 translational, 1 rotational).

\textbf{Note:} This choice for degrees of freedom (dof) assumes that all finite-size aspherical or spherical particles in your model will freely rotate, sampling all their rotational dof. It is possible to use a combination of interaction potentials and fixes that induce no torque or otherwise constrain some of all of your particles so that this is not the case. Then there are less dof and you should use the \textit{compute_modify extra} command to adjust the dof accordingly.

For example, an aspherical particle with all three of its shape parameters the same is a sphere. If it does not rotate, then it should have 3 dof instead of 6 in 3d (or 2 instead of 3 in 2d). A uniaxial aspherical particle has two of its three shape parameters the same. If it does not rotate around the axis perpendicular to its circular cross section, then it should have 5 dof instead of 6 in 3d. The latter is the case for uniaxial ellipsoids in a \textit{GayBerne model} since there is no induced torque around the optical axis. It will also be the case for bi-axial ellipsoids when exactly two of the semiaxes have the same length and the corresponding relative well depths are equal.

The translational kinetic energy is computed the same as is described by the \textit{compute temp} command. The rotational kinetic energy is computed as \( \frac{1}{2} I \ w^2 \), where \( I \) is the inertia tensor for the aspherical particle and \( w \) is its angular velocity, which is computed from its angular momentum.
Note: For 2d models, particles are treated as ellipsoids, not ellipses, meaning their moments of inertia will be the same as in 3d.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) and \( w^2 \) are replaced by \( vx*vy \) and \( wx*wy \) for the xy component, and the appropriate elements of the inertia tensor are used. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the dynamic option of the compute_modify command if this is not the case.

This compute subtracts out translational degrees-of-freedom due to fixes that constrain molecular motion, such as fix shake and fix rigid. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the extra option of the compute_modify command.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostatting.

The keyword/value option pairs are used in the following ways.

For the bias keyword, bias-ID refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This allows compute temp/sphere to compute its thermal temperature after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile. Thermostats that use this compute will work with this bias term. See the doc pages for individual computes that calculate a temperature and the doc pages for fixes that perform thermostating for more details.

For the dof keyword, a setting of all calculates a temperature that includes both translational and rotational degrees of freedom. A setting of rotate calculates a temperature that includes only rotational degrees of freedom.

19.122.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

19.122.5 Restrictions

This compute is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This compute requires that atoms store angular momentum and a quaternion as defined by the atom_style ellipsoid command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.
19.122.6 Related commands

*compute temp*

19.122.7 Default

*none*

19.123 compute temp/body command

19.123.1 Syntax

```
compute ID group-ID temp/body keyword value ...
```

- ID, group-ID are documented in *compute* command
- `temp/body` = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = *bias* or *dof*
  - *bias* value = bias-ID
    - bias-ID = ID of a temperature compute that removes a velocity bias
  - *dof* value = *all* or *rotate*
    - *all* = compute temperature of translational and rotational degrees of freedom
    - *rotate* = compute temperature of just rotational degrees of freedom

19.123.2 Examples

```
compute 1 all temp/body
compute myTemp mobile temp/body bias tempCOM
compute myTemp mobile temp/body dof rotate
```

19.123.3 Description

Define a computation that calculates the temperature of a group of body particles, including a contribution from both their translational and rotational kinetic energy. This differs from the usual *compute temp* command, which assumes point particles with only translational kinetic energy.

Only body particles can be included in the group. For 3d particles, each has 6 degrees of freedom (3 translational, 3 rotational). For 2d body particles, each has 3 degrees of freedom (2 translational, 1 rotational).

**Note:** This choice for degrees of freedom (dof) assumes that all body particles in your model will freely rotate, sampling all their rotational dof. It is possible to use a combination of interaction potentials and fixes that induce no torque or otherwise constrain some of all of your particles so that this is not the case. Then there are less dof and you should use the *compute_modify extra* command to adjust the dof accordingly.
The translational kinetic energy is computed the same as is described by the `compute temp` command. The rotational kinetic energy is computed as 1/2 I w^2, where I is the inertia tensor for the aspherical particle and w is its angular velocity, which is computed from its angular momentum.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formula, except that v^2 and w^2 are replaced by vx*vy and wx*wy for the xy component, and the appropriate elements of the inertia tensor are used. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out translational degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` doc page for a discussion of different ways to compute temperature and perform thermostatting.

The keyword/value option pairs are used in the following ways.

For the `bias` keyword, `bias-ID` refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This allows compute temp/sphere to compute its thermal temperature after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile. Thermostats that use this compute will work with this bias term. See the doc pages for individual computes that calculate a temperature and the doc pages for fixes that perform thermostatting for more details.

For the `dof` keyword, a setting of `all` calculates a temperature that includes both translational and rotational degrees of freedom. A setting of `rotate` calculates a temperature that includes only rotational degrees of freedom.

---

**19.123.4 Output info**

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

---

**19.123.5 Restrictions**

This compute is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

This compute requires that atoms store angular momentum and a quaternion as defined by the `atom_style body` command.

19.124.2 Examples

```
compute 1 fluid temp/chunk molchunk
compute 1 fluid temp/chunk molchunk temp internal
compute 1 fluid temp/chunk molchunk bias tpartial adof 2.0
```
19.124.3 Description

Define a computation that calculates the temperature of a group of atoms that are also in chunks, after optionally subtracting out the center-of-mass velocity of each chunk. By specifying optional values, it can also calculate the per-chunk temperature or energies of the multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

The temperature is calculated by the formula \( KE = DOF/2 \ k \ T \), where \( KE \) = total kinetic energy of all atoms assigned to chunks (sum of \( 1/2 \ m \ v^2 \)), \( DOF \) = the total number of degrees of freedom for those atoms, \( k \) = Boltzmann constant, and \( T \) = temperature.

The \( DOF \) is calculated as \( N*adof + Nchunk*cdof \), where \( N \) = number of atoms contributing to the \( KE \), \( adof \) = degrees of freedom per atom, and \( cdof \) = degrees of freedom per chunk. By default \( adof = 2 \) or \( 3 \) = dimensionality of system, as set via the `dimension` command, and \( cdof = 0.0 \). This gives the usual formula for temperature.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( vx*vy \) for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

Note that the number of atoms contributing to the temperature is calculated each time the temperature is evaluated since it is assumed the atoms may be dynamically assigned to chunks. Thus there is no need to use the `dynamic` option of the `compute modify` command for this compute style.

If any optional values are specified, then per-chunk quantities are also calculated and stored in a global array, as described below.

The `temp` value calculates the temperature for each chunk by the formula \( KE = DOF/2 \ k \ T \), where \( KE \) = total kinetic energy of the chunk of atoms (sum of \( 1/2 \ m \ v^2 \)), \( DOF \) = the total number of degrees of freedom for all atoms in the chunk, \( k \) = Boltzmann constant, and \( T \) = temperature.

The \( DOF \) in this case is calculated as \( N*adof + cdof \), where \( N \) = number of atoms in the chunk, \( adof \) = degrees of freedom per atom, and \( cdof \) = degrees of freedom per chunk. By default \( adof = 2 \) or \( 3 \) = dimensionality of system, as set via the `dimension` command, and \( cdof = 0.0 \). This gives the usual formula for temperature.

The `kecom` value calculates the kinetic energy of each chunk as if all its atoms were moving with the velocity of the center-of-mass of the chunk.

The `internal` value calculates the internal kinetic energy of each chunk. The internal KE is summed over the atoms in the chunk using an internal “thermal” velocity for each atom, which is its velocity minus the center-of-mass velocity of the chunk.

Note that currently the global and per-chunk temperatures calculated by this compute only include translational degrees of freedom for each atom. No rotational degrees of freedom are included for finite-size particles. Also no degrees of freedom are subtracted for any velocity bias or constraints that are applied, such as `compute temp/partial`, or `fix shake` or `fix rigid`. This is because those degrees of freedom (e.g. a constrained bond) could apply to sets of atoms that are both included and excluded from a specific chunk, and hence the concept is somewhat ill-defined. In some cases, you can use the `adof` and `cdof` keywords to adjust the calculated degrees of freedom appropriately, as explained below.

Note that the per-chunk temperature calculated by this compute and the `fix ave/chunk temp` command can be different. This compute calculates the temperature for each chunk for a single snapshot. Fix ave/chunk can do that but can also time average those values over many snapshots, or it can compute a temperature as if the atoms in the chunk on different timesteps were collected together as one set of atoms to calculate their temperature. This compute allows the center-of-mass velocity of each chunk to be subtracted before calculating the temperature; fix ave/chunk does not.
Note: Only atoms in the specified group contribute to the calculations performed by this compute. The \texttt{compute chunk/atom} command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

The simplest way to output the per-chunk results of the compute temp/chunk calculation to a file is to use the \texttt{fix ave/time} command, for example:

\begin{verbatim}
compute ccl all chunk/atom molecule
compute myChunk all temp/chunk ccl temp
fix 1 all ave/time 100 1 100 c_myChunk file tmp.out mode vector
\end{verbatim}

The keyword/value option pairs are used in the following ways.

The \texttt{com} keyword can be used with a value of \texttt{yes} to subtract the velocity of the center-of-mass for each chunk from the velocity of the atoms in that chunk, before calculating either the global or per-chunk temperature. This can be useful if the atoms are streaming or otherwise moving collectively, and you wish to calculate only the thermal temperature.

For the \texttt{bias} keyword, \texttt{bias-ID} refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This also allows calculation of the global or per-chunk temperature using only the thermal temperature of atoms in each chunk after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a velocity profile. It also applies to the calculation of the other per-chunk values, such as \texttt{kecom} or \texttt{internal}, which involve the center-of-mass velocity of each chunk, which is calculated after the velocity bias is removed from each atom. Note that the temperature compute will apply its bias globally to the entire system, not on a per-chunk basis.

The \texttt{adof} and \texttt{cdof} keywords define the values used in the degree of freedom (DOF) formulas used for the global or per-chunk temperature, as described above. They can be used to calculate a more appropriate temperature for some kinds of chunks. Here are 3 examples:

If spatially binned chunks contain some number of water molecules and \texttt{fix shake} is used to make each molecule rigid, then you could calculate a temperature with 6 degrees of freedom (DOF) (3 translational, 3 rotational) per molecule by setting \texttt{adof} to 2.0.

If \texttt{compute temp/partial} is used with the \texttt{bias} keyword to only allow the x component of velocity to contribute to the temperature, then \texttt{adof} = 1.0 would be appropriate.

If each chunk consists of a large molecule, with some number of its bonds constrained by \texttt{fix shake} or the entire molecule by \texttt{fix rigid/small}, \texttt{adof} = 0.0 and \texttt{cdof} could be set to the remaining degrees of freedom for the entire molecule (entire chunk in this case), e.g. 6 for 3d, or 3 for 2d, for a rigid molecule.

19.124.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the \texttt{Howto output} doc page for an overview of LAMMPS output options.

This compute also optionally calculates a global array, if one or more of the optional values are specified. The number of rows in the array = the number of chunks \texttt{Nchunk} as calculated by the specified \texttt{compute chunk/atom} command. The number of columns is the number of specified values (1 or more). These values can be accessed by any command that uses global array values from a compute as input. Again, see the \texttt{Howto output} doc page for an overview of LAMMPS output options.
The scalar value calculated by this compute is “intensive”. The vector values are “extensive”. The array values are “intensive”.

The scalar value will be in temperature units. The vector values will be in energy units. The array values will be in temperature units for the temp value, and in energy units for the kecom and internal values.

19.124.5 Restrictions

The com and bias keywords cannot be used together.

19.124.6 Related commands

compute temp, fix ave/chunk temp

19.124.7 Default

The option defaults are com no, no bias, adof = dimensionality of the system (2 or 3), and cdo = 0.0.

19.125 compute temp/com command

19.125.1 Syntax

```plaintext
compute ID group-ID temp/com
```

- ID, group-ID are documented in compute command
- temp/com = style name of this compute command

19.125.2 Examples

```plaintext
compute 1 all temp/com
compute myTemp mobile temp/com
```

19.125.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out the center-of-mass velocity of the group. This is useful if the group is expected to have a non-zero net velocity for some reason. A compute of this style can be used by any command that computes a temperature, e.g. thermo_modify, fix temp/rescale, fix npt, etc.

After the center-of-mass velocity has been subtracted from each atom, the temperature is calculated by the formula KE = dim/2 N k T, where KE = total kinetic energy of the group of atoms (sum of 1/2 m v^2), dim = 2 or 3 = dimensionality of the simulation, N = number of atoms in the group, k = Boltzmann constant, and T = temperature.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that v^2 is replaced by vx*vy for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.
The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the dynamic option of the compute_modify command if this is not the case.

The removal of the center-of-mass velocity by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include fix nvt, fix temp/rescale, fix temp/berendsen, and fix langevin.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as fix shake and fix rigid. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the extra option of the compute_modify command.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostatting.

### 19.125.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

19.126.2 Examples

```plaintext
compute oxygen_c-s all temp/cs 0_core 0_shell
compute core_shells all temp/cs cores shells
```

19.126.3 Description

Define a computation that calculates the temperature of a system based on the center-of-mass velocity of atom pairs that are bonded to each other. This compute is designed to be used with the adiabatic core/shell model of (Mitchell and Finchham). See the Howto coreshell doc page for an overview of the model as implemented in LAMMPS. Specifically, this compute enables correct temperature calculation and thermostatting of core/shell pairs where it is desirable for the internal degrees of freedom of the core/shell pairs to not be influenced by a thermostat. A compute of this style can be used by any command that computes a temperature via fix_modify e.g. fix temp/rescale, fix npt, etc.

Note that this compute does not require all ions to be polarized, hence defined as core/shell pairs. One can mix core/shell pairs and ions without a satellite particle if desired. The compute will consider the non-polarized ions according to the physical system.

For this compute, core and shell particles are specified by two respective group IDs, which can be defined using the group command. The number of atoms in the two groups must be the same and there should be one bond defined between a pair of atoms in the two groups. Non-polarized ions which might also be included in the treated system should not be included into either of these groups, they are taken into account by the group-ID (second argument) of the compute.

The temperature is calculated by the formula KE = dim/2 N k T, where KE = total kinetic energy of the group of atoms (sum of 1/2 m v^2), dim = 2 or 3 = dimensionality of the simulation, N = number of atoms in the group, k = Boltzmann constant, and T = temperature. Note that the velocity of each core or shell atom used in the KE calculation is the velocity of the center-of-mass (COM) of the core/shell pair the atom is part of.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that v^2 is replaced by vx*vy for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz. In contrast to the temperature, the velocity of each core or shell atom is taken individually.

The change this fix makes to core/shell atom velocities is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. This “bias” is the velocity of the atom relative to the COM velocity of the core/shell pair. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining COM velocity will be performed, and the bias will be added back in. This means the thermostatting will effectively be performed on the core/shell pairs, instead of on the individual core and shell atoms. Thermostatting fixes that work in this way include fix nvt, fix temp/rescale, fix temp/berendsen, and fix langevin.

The internal energy of core/shell pairs can be calculated by the compute temp/chunk command, if chunks are defined as core/shell pairs. See the Howto coreshell doc page doc page for more discussion on how to do this.
19.126.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

19.126.5 Restrictions

The number of core/shell pairs contributing to the temperature is assumed to be constant for the duration of the run. No fixes should be used which generate new molecules or atoms during a simulation.

19.126.6 Related commands

compute temp, compute temp/chunk

19.126.7 Default

- temp/deform = style name of this compute command

19.127.2 Examples

```
compute myTemp all temp/deform
```
19.127.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out a streaming velocity induced by the simulation box changing size and/or shape, for example in a non-equilibrium MD (NEMD) simulation. The size/shape change is induced by use of the fix deform command. A compute of this style is created by the fix nvt/sllod command to compute the thermal temperature of atoms for thermostatting purposes. A compute of this style can also be used by any command that computes a temperature, e.g. thermo_modify, fix temp/rescale, fix npt, etc.

The deformation fix changes the box size and/or shape over time, so each atom in the simulation box can be thought of as having a “streaming” velocity. For example, if the box is being sheared in x, relative to y, then atoms at the bottom of the box (low y) have a small x velocity, while atoms at the top of the box (hi y) have a large x velocity. This position-dependent streaming velocity is subtracted from each atom’s actual velocity to yield a thermal velocity which is used to compute the temperature.

Note: Fix deform has an option for remapping either atom coordinates or velocities to the changing simulation box. When using this compute in conjunction with a deforming box, fix deform should NOT remap atom positions, but rather should let atoms respond to the changing box by adjusting their own velocities (or let fix deform remap the atom velocities, see it's remap option). If fix deform does remap atom positions, then they appear to move with the box but their velocity is not changed, and thus they do NOT have the streaming velocity assumed by this compute. LAMMPS will warn you if fix deform is defined and its remap setting is not consistent with this compute.

After the streaming velocity has been subtracted from each atom, the temperature is calculated by the formula KE = dim/2 N k T, where KE = total kinetic energy of the group of atoms (sum of 1/2 m v^2), dim = 2 or 3 = dimensionality of the simulation, N = number of atoms in the group, k = Boltzmann constant, and T = temperature. Note that v in the kinetic energy formula is the atom’s thermal velocity.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that v^2 is replaced by vx*vy for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the dynamic option of the compute_modify command if this is not the case.

The removal of the box deformation velocity component by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include fix nvt, fix temp/rescale, fix temp/berendsen, and fix langevin.

Note: The temperature calculated by this compute is only accurate if the atoms are indeed moving with a stream velocity profile that matches the box deformation. If not, then the compute will subtract off an incorrect stream velocity, yielding a bogus thermal temperature. You should NOT assume that your atoms are streaming at the same rate the box is deforming. Rather, you should monitor their velocity profile, e.g. via the fix ave/chunk command. And you can compare the results of this compute to compute temp/profile, which actually calculates the stream profile before subtracting it. If the two computes do not give roughly the same temperature, then your atoms are not streaming consistent with the box deformation. See the fix deform command for more details on ways to get atoms to stream consistently with the box deformation.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as fix shake and fix rigid. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the extra option of the compute_modify command.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostatting.
19.127.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

compute myTemp all temp/deform/eff

19.128.3 Description

Define a computation that calculates the temperature of a group of nuclei and electrons in the electron force field model, after subtracting out a streaming velocity induced by the simulation box changing size and/or shape, for example in a non-equilibrium MD (NEMD) simulation. The size/shape change is induced by use of the fix deform command. A compute of this style is created by the fix nvt/sllod/eff command to compute the thermal temperature of atoms for thermostating purposes. A compute of this style can also be used by any command that computes a temperature, e.g. thermo_modify, fix npt/eff, etc.

The calculation performed by this compute is exactly like that described by the compute temp/deform command, except that the formula for the temperature includes the radial electron velocity contributions, as discussed by the compute temp/eff command. Note that only the translational degrees of freedom for each nuclei or electron are affected by the streaming velocity adjustment. The radial velocity component of the electrons is not affected.
19.128.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

19.129.2 Examples

```
compute TDRUDE all temp/drude
```

19.129.3 Description

Define a computation that calculates the temperatures of core-Drude pairs. This compute is designed to be used with the thermalized Drude oscillator model. Polarizable models in LAMMPS are described on the Howto polarizable doc page.

Drude oscillators consist of a core particle and a Drude particle connected by a harmonic bond, and the relative motion of these Drude oscillators is usually maintained cold by a specific thermostat that acts on the relative motion of the core-Drude particle pairs. Therefore, because LAMMPS considers Drude particles as normal atoms in its default temperature compute (compute temp command), the reduced temperature of the core-Drude particle pairs is not calculated correctly.
By contrast, this compute calculates the temperature of the cores using center-of-mass velocities of the core-Drude pairs, and the reduced temperature of the Drude particles using the relative velocities of the Drude particles with respect to their cores. Non-polarizable atoms are considered as cores. Their velocities contribute to the temperature of the cores.

19.129.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6, which can be accessed by indices 1-6, whose components are

1. temperature of the centers of mass (temperature units)
2. temperature of the dipoles (temperature units)
3. number of degrees of freedom of the centers of mass
4. number of degrees of freedom of the dipoles
5. kinetic energy of the centers of mass (energy units)
6. kinetic energy of the dipoles (energy units)

These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

Both the scalar value and the first two values of the vector calculated by this compute are “intensive”. The other 4 vector values are “extensive”.

19.129.5 Restrictions

The number of degrees of freedom contributing to the temperature is assumed to be constant for the duration of the run unless the fix modify command sets the option dynamic yes.

19.129.6 Related commands

19.129.7 Default

none

19.130 compute temp/eff command

19.130.1 Syntax

compute ID group-ID temp/eff

- ID, group-ID are documented in compute command
- temp/eff = style name of this compute command
19.130.2 Examples

\begin{verbatim}
compute 1 all temp/eff
compute myTemp mobile temp/eff
\end{verbatim}

19.130.3 Description

Define a computation that calculates the temperature of a group of nuclei and electrons in the electron force field model. A compute of this style can be used by commands that compute a temperature, e.g. `thermo_modify`, `fix npt/eff`, etc.

The temperature is calculated by the formula \( KE = \frac{\text{dim}}{2} N k T \), where \( KE \) = total kinetic energy of the group of atoms (sum of \( \frac{1}{2} m v^2 \) for nuclei and sum of \( \frac{1}{2} (m v^2 + \frac{3}{4} m s^2) \) for electrons, where \( s \) includes the radial electron velocity contributions), \( \text{dim} = 2 \) or \( 3 \) = dimensionality of the simulation, \( N \) = number of atoms (only total number of nuclei in the eFF (see the `pair_eff` command) in the group, \( k \) = Boltzmann constant, and \( T \) = temperature. This expression is summed over all nuclear and electronic degrees of freedom, essentially by setting the kinetic contribution to the heat capacity to \( \frac{3}{2}k \) (where only nuclei contribute). This subtlety is valid for temperatures well below the Fermi temperature, which for densities two to five times the density of liquid H2 ranges from 86,000 to 170,000 K.

**Note:** For eFF models, in order to override the default temperature reported by LAMMPS in the thermodynamic quantities reported via the `thermo` command, the user should apply a `thermo_modify` command, as shown in the following example:

\begin{verbatim}
compute effTemp all temp/eff
thermo_style custom step etotal pe ke temp press
thermo_modify temp effTemp
\end{verbatim}

A 6-component kinetic energy tensor is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( vx^2 \) for the xy component, etc. For the eFF, again, the radial electronic velocities are also considered.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the *Howto thermostat* doc page for a discussion of different ways to compute temperature and perform thermostatting.

19.130.4 Output info

The scalar value calculated by this compute is “intensive”, meaning it is independent of the number of atoms in the simulation. The vector values are “extensive”, meaning they scale with the number of atoms in the simulation.
19.130.5 Restrictions

This compute is part of the USER-EFF package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.130.6 Related commands

compute temp/partial, compute temp/region, compute pressure

19.130.7 Default

19.131 compute temp/partial command

19.131.1 Syntax

\[
\text{compute ID group-ID temp/partial xflag yflag zflag}
\]

- ID, group-ID are documented in compute command
- temp/partial = style name of this compute command
- xflag, yflag, zflag = 0/1 for whether to exclude/include this dimension

19.131.2 Examples

\[
\text{compute newT flow temp/partial 1 1 0}
\]

19.131.3 Description

Define a computation that calculates the temperature of a group of atoms, after excluding one or more velocity components. A compute of this style can be used by any command that computes a temperature, e.g. thermo_modify, fix temp/rescale, fix npt, etc.

The temperature is calculated by the formula \( KE = \frac{\text{dim}}{2} N k T \), where \( KE \) = total kinetic energy of the group of atoms (sum of \( \frac{1}{2} m v^2 \)), \( \text{dim} \) = dimensionality of the simulation, \( N \) = number of atoms in the group, \( k \) = Boltzmann constant, and \( T \) = temperature. The calculation of \( KE \) excludes the x, y, or z dimensions if \( xflag, yflag, zflag = 0 \).

The \( \text{dim} \) parameter is adjusted to give the correct number of degrees of freedom.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the calculation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( vx*vy \) for the xy component, etc. The 6 components of the vector are ordered \( xx, yy, zz, xy, xz, yz \).

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the dynamic option of the compute_modify command if this is not the case.

The removal of velocity components by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed.
and the bias will be added back in. Thermostatting fixes that work in this way include \texttt{fix nvt}, \texttt{fix temp/rescale}, \texttt{fix temp/berendsen}, and \texttt{fix langevin}.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as \texttt{fix shake} and \texttt{fix rigid}. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the \texttt{extra} option of the \texttt{compute modify} command.

See the \texttt{Howto thermostat} doc page for a discussion of different ways to compute temperature and perform thermostatting.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \texttt{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

### 19.131.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the \texttt{Howto output} doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature \texttt{units}. The vector values will be in energy \texttt{units}.

compute myTemp flow temp/profile 1 1 1 x 10 out bin 
compute myTemp flow temp/profile 0 1 1 xyz 20 20 20 
```

19.132.3  Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out a spatially-averaged center-of-mass velocity field, before computing the kinetic energy. This can be useful for thermostating a collection of atoms undergoing a complex flow, e.g. via a profile-unbiased thermostat (PUT) as described in (Evans). A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

The `xflag`, `yflag`, `zflag` settings determine which components of average velocity are subtracted out.

The `binstyle` setting and its `Nx`, `Ny`, `Nz` arguments determine how bins are setup to perform spatial averaging. “Bins” can be 1d slabs, 2d pencils, or 3d bricks depending on which `binstyle` is used. The simulation box is partitioned conceptually into `Nx` by `Ny` by `Nz` bins. Depending on the `binstyle`, you may only specify one or two of these values; the others are effectively set to 1 (no binning in that dimension). For non-orthogonal (triclinic) simulation boxes, the bins are “tilted” slabs or pencils or bricks that are parallel to the tilted faces of the box. See the `region prism` command for a discussion of the geometry of tilted boxes in LAMMPS.

When a temperature is computed, the center-of-mass velocity for the set of atoms that are both in the compute group and in the same spatial bin is calculated. This bias velocity is then subtracted from the velocities of individual atoms in the bin to yield a thermal velocity for each atom. Note that if there is only one atom in the bin, its thermal velocity will thus be 0.0.
After the spatially-averaged velocity field has been subtracted from each atom, the temperature is calculated by the formula $KE = (\text{dim} \times N - \text{dim} \times N_x \times N_y \times N_z) \frac{k}{2} T$, where $KE = \text{total kinetic energy of the group of atoms (sum of } \frac{1}{2} m v^2)$, dim = 2 or 3 = dimensionality of the simulation, $N = \text{number of atoms in the group}$, $k = \text{Boltzmann constant}$, and $T = \text{temperature}$. The $\text{dim} \times N_x \times N_y \times N_z$ term are degrees of freedom subtracted to adjust for the removal of the center-of-mass velocity in each of $N_x \times N_y \times N_z$ bins, as discussed in the (Evans) paper.

If the out keyword is used with a tensor value, which is the default, a kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $vx \times vy$ for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

If the out keyword is used with a bin value, the count of atoms and computed temperature for each bin are stored for output, as an array of values, as described below. The temperature of each bin is calculated as described above, where the bias velocity is subtracted and only the remaining thermal velocity of atoms in the bin contributes to the temperature. See the note below for how the temperature is normalized by the degrees-of-freedom of atoms in the bin.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the dynamic option of the compute_modify command if this is not the case.

The removal of the spatially-averaged velocity field by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include fix nvt, fix temp/rescale, fix temp/berendsen, and fix langevin.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as fix shake and fix rigid. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the extra option of the compute_modify command.

Note: When using the out keyword with a value of bin, the calculated temperature for each bin does not include the degrees-of-freedom adjustment described in the preceding paragraph, for fixes that constrain molecular motion. It does include the adjustment due to the extra option, which is applied to each bin.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostatting. Using this compute in conjunction with a thermostatting fix, as explained there, will effectively implement a profile-unbiased thermostat (PUT), as described in (Evans).

**19.132.4 Output info**

This compute calculates a global scalar (the temperature). Depending on the setting of the out keyword, it also calculates a global vector or array. For out = tensor, it calculates a vector of length 6 (KE tensor), which can be accessed by indices 1-6. For out = bin it calculates a global array which has 2 columns and N rows, where N is the number of bins. The first column contains the number of atoms in that bin. The second contains the temperature of that bin, calculated as described above. The ordering of rows in the array is as follows. Bins in x vary fastest, then y, then z. Thus for a 10x10x10 3d array of bins, there will be 1000 rows. The bin with indices ix,iy,iz = 2,3,4 would map to row $M = (iz-1) \times 10^2 + (iy-1) \times 10 + ix = 322$, where the rows are numbered from 1 to 1000 and the bin indices are numbered from 1 to 10 in each dimension.

These values can be used by any command that uses global scalar or vector or array values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”. The array values are “intensive”.

The scalar value will be in temperature units. The vector values will be in energy units. The first column of array values are counts; the values in the second column will be in temperature units.
19.132.5 Restrictions

You should not use too large a velocity-binning grid, especially in 3d. In the current implementation, the binned velocity averages are summed across all processors, so this will be inefficient if the grid is too large, and the operation is performed every timestep, as it will be for most thermostats.

- ID, group-ID are documented in compute command
- temp/ramp = style name of this compute command
- vdim = vx or vy or vz
- vlo,vhi = subtract velocities between vlo and vhi (velocity units)
- dim = x or y or z
- clo,chi = lower and upper bound of domain to subtract from (distance units)
- zero or more keyword/value pairs may be appended
- keyword = units
  units value = lattice or box

19.133.2 Examples

compute 2nd middle temp/ramp vx 0 8 y 2 12 units lattice
19.133.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out an ramped velocity profile before computing the kinetic energy. A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

The meaning of the arguments for this command which define the velocity ramp are the same as for the `velocity_ramp` command which was presumably used to impose the velocity.

After the ramp velocity has been subtracted from the specified dimension for each atom, the temperature is calculated by the formula \( KE = \frac{\text{dim}}{2} N k T \), where \( KE \) = total kinetic energy of the group of atoms (sum of \( \frac{1}{2} m v^2 \)), dim = 2 or 3 = dimensionality of the simulation, N = number of atoms in the group, k = Boltzmann constant, and T = temperature.

The `units` keyword determines the meaning of the distance units used for coordinates (c1,c2) and velocities (vlo,vhi). A `box` value selects standard distance units as defined by the `units` command, e.g. Angstroms for units = real or metal. A `lattice` value means the distance units are in lattice spacings; e.g. velocity = lattice spacings / tau. The `lattice` command must have been previously used to define the lattice spacing.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( vx*vy \) for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

The removal of the ramped velocity component by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` doc page for a discussion of different ways to compute temperature and perform thermostatting.

19.133.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature `units`. The vector values will be in energy `units`.
19.133.5 Restrictions

19.133.7 Default

The option default is units = lattice.

19.134 compute temp/region command

19.134.1 Syntax

compute ID group-ID temp/region region-ID

- ID, group-ID are documented in compute command
- temp/region = style name of this compute command
- region-ID = ID of region to use for choosing atoms

19.134.2 Examples

compute mine flow temp/region boundary

19.134.3 Description

Define a computation that calculates the temperature of a group of atoms in a geometric region. This can be useful for thermostating one portion of the simulation box. E.g. a McDLT simulation where one side is cooled, and the other side is heated. A compute of this style can be used by any command that computes a temperature, e.g. thermo_modify, fix temp/rescale, etc.

Note that a region-style temperature can be used to thermostat with fix temp/rescale or fix langevin, but should probably not be used with Nose/Hoover style fixes (fix nvt, fix npt, or fix nph), if the degrees-of-freedom included in the computed T varies with time.

The temperature is calculated by the formula KE = dim/2 N k T, where KE = total kinetic energy of the group of atoms (sum of 1/2 m v^2), dim = 2 or 3 = dimensionality of the simulation, N = number of atoms in both the group and region, k = Boltzmann constant, and T = temperature.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that v^2 is replaced by vx*vy for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is calculated each time the temperature is evaluated since it is assumed atoms can enter/leave the region. Thus there is no need to use the dynamic option of the compute_modify command for this compute style.
The removal of atoms outside the region by this fix is essentially computing the temperature after a “bias” has been removed, which in this case is the velocity of any atoms outside the region. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`. This means that when this compute is used to calculate the temperature for any of the thermostatting fixes via the `fix modify temp` command, the thermostat will operate only on atoms that are currently in the geometric region.

Unlike other compute styles that calculate temperature, this compute does not subtract out degrees-of-freedom due to fixes that constrain motion, such as `fix shake` and `fix rigid`. This is because those degrees of freedom (e.g. a constrained bond) could apply to sets of atoms that straddle the region boundary, and hence the concept is somewhat ill-defined. If needed the number of subtracted degrees-of-freedom can be set explicitly using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` doc page for a discussion of different ways to compute temperature and perform thermostatting.

### 19.134.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. - ID, group-ID are documented in \texttt{compute} command
- temp/rotate = style name of this compute command
19.136.2 Examples

\texttt{compute Tbead bead temp/rotate}

19.136.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out the center-of-mass velocity and angular velocity of the group. This is useful if the group is expected to have a non-zero net velocity and/or global rotation motion for some reason. A compute of this style can be used by any command that computes a temperature, e.g. \texttt{thermo_modify}, \texttt{fix temp/rescale}, \texttt{fix npt}, etc.

After the center-of-mass velocity and angular velocity has been subtracted from each atom, the temperature is calculated by the formula $KE = \frac{\text{dim}}{2} N k T$, where $KE = \text{total kinetic energy of the group of atoms}$ (sum of $\frac{1}{2} m v^2$), $\text{dim} = 2$ or $3 = \text{dimensionality of the simulation}$, $N = \text{number of atoms in the group}$, $k = \text{Boltzmann constant}$, and $T = \text{temperature}$.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $v_x v_y$ for the xy component, etc. The 6 components of the vector are ordered $xx, yy, zz, xy, xz, yz$.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the \texttt{dynamic} option of the \texttt{compute_modify} command if this is not the case.

The removal of the center-of-mass velocity and angular velocity by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include \texttt{fix nvt}, \texttt{fix temp/rescale}, \texttt{fix temp/berendsen}, and \texttt{fix langevin}.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as \texttt{fix shake} and \texttt{fix rigid}. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the \texttt{extra} option of the \texttt{compute_modify} command.

See the \texttt{Howto thermostat} doc page for a discussion of different ways to compute temperature and perform thermostatting.

19.136.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the \texttt{Howto output} doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature \textit{units}. The vector values will be in energy \textit{units}.
19.136.5 Restrictions

This compute is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

19.136.6 Related commands

*compute temp*

19.136.7 Default

none

19.137 compute temp/sphere command

19.137.1 Syntax

```
compute ID group-ID temp/sphere keyword value ...
```

- ID, group-ID are documented in *compute* command
- temp/sphere = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = *bias* or *dof*
  - *bias*
    - value = bias-ID
      - bias-ID = ID of a temperature compute that removes a velocity bias
  - *dof*
    - value = all or rotate
      - all = compute temperature of translational and rotational degrees of freedom
      - rotate = compute temperature of just rotational degrees of freedom

19.137.2 Examples

```
compute 1 all temp/sphere
compute myTemp mobile temp/sphere bias tempCOM
compute myTemp mobile temp/sphere dof rotate
```

19.137.3 Description

Define a computation that calculates the temperature of a group of spherical particles, including a contribution from both their translational and rotational kinetic energy. This differs from the usual *compute temp* command, which assumes point particles with only translational kinetic energy.

Both point and finite-size particles can be included in the group. Point particles do not rotate, so they have only 3 translational degrees of freedom. For 3d spherical particles, each has 6 degrees of freedom (3 translational, 3 rotational). For 2d spherical particles, each has 3 degrees of freedom (2 translational, 1 rotational).
Note: This choice for degrees of freedom (dof) assumes that all finite-size spherical particles in your model will freely rotate, sampling all their rotational dof. It is possible to use a combination of interaction potentials and fixes that induce no torque or otherwise constrain some of all of your particles so that this is not the case. Then there are less dof and you should use the `compute_modify extra` command to adjust the dof accordingly.

The translational kinetic energy is computed the same as is described by the `compute temp` command. The rotational kinetic energy is computed as \( \frac{1}{2} I w^2 \), where \( I \) is the moment of inertia for a sphere and \( w \) is the particle’s angular velocity.

Note: For 2d models, particles are treated as spheres, not disks, meaning their moment of inertia will be the same as in 3d.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formulas, except that \( v^2 \) and \( w^2 \) are replaced by \( vx*vy \) and \( wx*wy \) for the xy component. The 6 components of the vector are ordered \( xx, yy, zz, xy, xz, yz \).

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out translational degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` doc page for a discussion of different ways to compute temperature and perform thermostatting.

The keyword/value option pairs are used in the following ways.

For the `bias` keyword, `bias-ID` refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This allows `compute temp/sphere` to compute its thermal temperature after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile. Thermostats that use this compute will work with this bias term. See the doc pages for individual computes that calculate a temperature and the doc pages for fixes that perform thermostatting for more details.

For the `dof` keyword, a setting of `all` calculates a temperature that includes both translational and rotational degrees of freedom. A setting of `rotate` calculates a temperature that includes only rotational degrees of freedom.

19.137.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.
19.137.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the atom_style sphere command.

All particles in the group must be finite-size spheres, or point particles with radius = 0.0.

19.137.6 Related commands

compute temp, compute temp/asphere

19.137.7 Default

The option defaults are no bias and dof = all.

19.138 compute temp/uef command

19.138.1 Syntax

compute ID group-ID temp/uef

• ID, group-ID are documented in compute command
• temp/uef = style name of this compute command

19.138.2 Examples

compute 1 all temp/uef
compute 2 sel temp/uef

19.138.3 Description

This command is used to compute the kinetic energy tensor in the reference frame of the applied flow field when fix nvt/uef or fix npt/uef is used. It is not necessary to use this command to compute the scalar value of the temperature. A compute temp may be used for that purpose.

Output information for this command can be found in the documentation for compute temp.

19.138.4 Restrictions

This fix is part of the USER-UEF package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This command can only be used when fix nvt/uef or fix npt/uef is active.

compute 1 all ti lj/cut 1*3 v_lj v_dlj coul/long * v_c v_dc kspace * v_ks v_dks
```
19.139.3 Description

Define a computation that calculates the derivative of the interaction potential with respect to lambda, the coupling parameter used in a thermodynamic integration. This derivative can be used to infer a free energy difference resulting from an alchemical simulation, as described in Eike.

Typically this compute will be used in conjunction with the fix adapt command which can perform alchemical transformations by adjusting the strength of an interaction potential as a simulation runs, as defined by one or more pair_style or kspace_style commands. This scaling is done via a prefactor on the energy, forces, virial calculated by the pair or K-Space style. The prefactor is often a function of a lambda parameter which may be adjusted from 0 to 1 (or vice versa) over the course of a run. The time-dependent adjustment is what the fix adapt command does.

Assume that the unscaled energy of a pair_style or kspace_style is given by \( U \). Then the scaled energy is

\[
Us = f(\lambda) \cdot U
\]

where \( f() \) is some function of lambda. What this compute calculates is

\[
\frac{dUs}{d\lambda} = \frac{U \cdot df(\lambda)/d\lambda}{Us / f(\lambda) \cdot df(\lambda)/d\lambda}
\]

which is the derivative of the system’s scaled potential energy \( Us \) with respect to \( \lambda \).

To perform this calculation, you provide one or more atom types as atype. Atype can be specified in one of two ways. An explicit numeric values can be used, as in the first example above. Or a wildcard asterisk can be used in place of or in conjunction with the atype argument to select multiple atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If \( N \) = the number of atom types, then an asterisk with no numeric values means all types from 1 to \( N \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( N \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive).

You also specify two functions, as equal-style variables. The first is specified as \( v_{name1} \), where \( name1 \) is the name of the variable, and is \( f(\lambda) \) in the notation above. The second is specified as \( v_{name2} \), where \( name2 \) is the name of the variable, and is \( df(\lambda) / d\lambda \) in the notation above. I.e. it is the analytic derivative of \( f() \) with respect to \( \lambda \). Note that the \( name1 \) variable is also typically given as an argument to the fix adapt command.

An alchemical simulation may use several pair potentials together, invoked via the pair_style hybrid or hybrid/overlay command. The total \( dU/d\lambda \) for the overall system is calculated as the sum of each contributing term as listed by the keywords in the compute ti command. Individual pair potentials can be listed, which will be sub-styles in the hybrid case. You can also include a K-space term via the kspace keyword. You can also include a pairwise long-range tail correction to the energy via the tail keyword.

For each term you can specify a different (or the same) scale factor by the two variables that you list. Again, these will typically correspond to the scale factors applied to these various potentials and the K-Space contribution via the fix adapt command.

More details about the exact functional forms for the computation of \( du/dl \) can be found in the paper by Eike.

19.139.4 Output info

This compute calculates a global scalar, namely \( dU/d\lambda \). This value can be used by any command that uses a global scalar value from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”.

The scalar value will be in energy units.
19.139.5 Restrictions

This compute is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.140 compute torque/chunk command

19.140.1 Syntax

```
compute ID group-ID torque/chunk chunkID
```

- ID, group-ID are documented in compute command
- torque/chunk = style name of this compute command
- chunkID = ID of compute chunk/atom command

19.140.2 Examples

```
compute 1 fluid torque/chunk molchunk
```

19.140.3 Description

Define a computation that calculates the torque on multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and Howto chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the 3 components of the torque vector for each chunk, due to the forces on the individual atoms in the chunk around the center-of-mass of the chunk. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The compute chunk/atom command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.
Note: The coordinates of an atom contribute to the chunk’s torque in “unwrapped” form, by using the image flags associated with each atom. See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the set image command.

The simplest way to output the results of the compute torque/chunk calculation to a file is to use the fix ave/time command, for example:

```
compute ccl all chunk/atom molecule
compute myChunk all torque/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

19.140.4 Output info

This compute calculates a global array where the number of rows = the number of chunks Nchunk as calculated by the specified compute chunk/atom command. The number of columns = 3 for the 3 xyz components of the torque for each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in force-distance units.

19.141 compute vacf command

19.141.1 Syntax

```
compute ID group-ID vacf
```

- ID, group-ID are documented in compute command
- vacf = style name of this compute command
### 19.141.2 Examples

```
compute 1 all vacf
compute 1 upper vacf
```

### 19.141.3 Description

Define a computation that calculates the velocity auto-correlation function (VACF), averaged over a group of atoms. Each atom’s contribution to the VACF is its current velocity vector dotted into its initial velocity vector at the time the compute was specified.

A vector of four quantities is calculated by this compute. The first 3 elements of the vector are \( v_x \times v_x0 \) (and similarly for the y and z components), summed and averaged over atoms in the group. \( v_x \) is the current x-component of velocity for the atom, \( v_x0 \) is the initial x-component of velocity for the atom. The fourth element of the vector is the total VACF, i.e. \( (v_x\times v_x0 + v_y\times v_y0 + v_z\times v_z0) \), summed and averaged over atoms in the group.

The integral of the VACF versus time is proportional to the diffusion coefficient of the diffusing atoms. This can be computed in the following manner, using the `variable` `trap()` function:

```
compute 2 all vacf
fix 5 all vector 1 c_2[4]
variable diff equal dt*trap(f_5)
thermo_style custom step v_diff
```

**Note:** If you want the quantities calculated by this compute to be continuous when running from a restart file, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with time=0 atom velocities from the restart file.

### 19.141.4 Output info

This compute calculates a global vector of length 4, which can be accessed by indices 1-4 by any command that uses global vector values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The vector values will be in velocity^2 units.

```
19.143.3 Description

Define a computation that calculates the velocity amplitude of a group of atoms with a cosine-shaped velocity profile and the temperature of them after subtracting out the velocity profile before computing the kinetic energy. A compute of this style can be used by any command that computes a temperature, e.g. thermo_modify, fix npt, etc.

This command together with fix_accelerate/cos enables viscosity calculation with periodic perturbation method, as described by Hess. An acceleration along the x-direction is applied to the simulation system by using fix_accelerate/cos command. The acceleration is a periodic function along the z-direction:

\[ a_x(z) = A \cos \left( \frac{2 \pi z}{l_z} \right) \]

where \( A \) is the acceleration amplitude, \( l_z \) is the z-length of the simulation box. At steady state, the acceleration generates a velocity profile:

\[ v_x(z) = V \cos \left( \frac{2 \pi z}{l_z} \right) \]

The generated velocity amplitude \( V \) is related to the shear viscosity \( \eta \) by:

\[ V = \frac{A \rho}{\eta} \left( \frac{l_z}{2 \pi} \right)^2 \]

and it can be obtained from ensemble average of the velocity profile:

\[ V = \frac{\sum_i 2m_i v_{i,x} \cos \left( \frac{2 \pi z_i}{l_z} \right)}{\sum_i m_i} \]

where \( m_i, v_{i,x} \) and \( z_i \) are the mass, x-component velocity and z coordinate of a particle.

After the cosine-shaped collective velocity in x direction has been subtracted for each atom, the temperature is calculated by the formula \( KE = \text{dim}/2 N k T \), where \( KE = \text{total kinetic energy of the group of atoms (sum of } 1/2 m v^2) \), \( \text{dim} = 2 \) or \( 3 = \text{dimensionality of the simulation} \), \( N = \text{number of atoms in the group} \), \( k = \text{Boltzmann constant} \), and \( T = \text{temperature} \).

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( v_x v_y \) for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the dynamic option of the compute_modify command if this is not the case. However, in order to get meaningful result, the group ID of this compute should be all.

The removal of the cosine-shaped velocity component by this command is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostating fixes that work in this way include fix nvt, fix temp/rescale, fix temp/berendsen, and fix langevin.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as fix shake and fix rigid. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the extra option of the compute_modify command.

See the Howto thermostat doc page for a discussion of different ways to compute temperature and perform thermostating.
## 19.143.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 7, which can be accessed by indices 1-7. The first 6 elements of the vector are the KE tensor, and the 7-th is the cosine-shaped velocity amplitude \( V \), which can be used to calculate the reciprocal viscosity, as shown in the example. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The first 6 elements of vector values are “extensive”, and the 7-th element of vector values is “intensive”.

The scalar value will be in temperature units. The first 6 elements of vector values will be in energy units. The 7-th element of vector value will be in velocity units.

## 19.143.5 Restrictions

This command is only available when LAMMPS was built with the USER-MISC package. Since this compute depends on `fix accelerate/cos` which can only work for 3d systems, it cannot be used for 2d systems.

19.144.3 Description

Define a computation that calculates the Voronoi tessellation of the atoms in the simulation box. The tessellation is calculated using all atoms in the simulation, but non-zero values are only stored for atoms in the group.

By default two per-atom quantities are calculated by this compute. The first is the volume of the Voronoi cell around each atom. Any point in an atom’s Voronoi cell is closer to that atom than any other. The second is the number of faces of the Voronoi cell. This is equal to the number of nearest neighbors of the central atom, plus any exterior faces (see note below). If the peratom keyword is set to “no”, the per-atom quantities are still calculated, but they are not accessible.

If the only_group keyword is specified the tessellation is performed only with respect to the atoms contained in the compute group. This is equivalent to deleting all atoms not contained in the group prior to evaluating the tessellation.

If the surface keyword is specified a third quantity per atom is computed: the Voronoi cell surface of the given atom. surface takes a group ID as an argument. If a group other than all is specified, only the Voronoi cell facets facing a neighbor atom from the specified group are counted towards the surface area.

In the example above, a precipitate embedded in a matrix, only atoms at the surface of the precipitate will have non-zero surface area, and only the outward facing facets of the Voronoi cells are counted (the hull of the precipitate). The total surface area of the precipitate can be obtained by running a “reduce sum” compute on c_2[3]

If the radius keyword is specified with an atom style variable as the argument, a poly-disperse Voronoi tessellation is performed. Examples for radius variables are

```
variable r1 atom (type==1)*0.1+(type==2)*0.4
compute radius all property/atom radius

variable r2 atom c_radius
```

Here v_r1 specifies a per-type radius of 0.1 units for type 1 atoms and 0.4 units for type 2 atoms, and v_r2 accesses the radius property present in atom_style sphere for granular models.
The `edge_histo` keyword activates the compilation of a histogram of number of edges on the faces of the Voronoi cells in the compute group. The argument `maxedge` of the this keyword is the largest number of edges on a single Voronoi cell face expected to occur in the sample. This keyword adds the generation of a global vector with `maxedge+1` entries. The last entry in the vector contains the number of faces with more than `maxedge` edges. Since the polygon with the smallest amount of edges is a triangle, entries 1 and 2 of the vector will always be zero.

The `edge_threshold` and `face_threshold` keywords allow the suppression of edges below a given minimum length and faces below a given minimum area. Ultra short edges and ultra small faces can occur as artifacts of the Voronoi tessellation. These keywords will affect the neighbor count and edge histogram outputs.

If the `occupation` keyword is specified the tessellation is only performed for the first invocation of the compute and then stored. For all following invocations of the compute the number of atoms in each Voronoi cell in the stored tessellation is counted. In this mode the compute returns a per-atom array with 2 columns. The first column is the number of atoms currently in the Voronoi volume defined by this atom at the time of the first invocation of the compute (note that the atom may have moved significantly). The second column contains the total number of atoms sharing the Voronoi cell of the stored tessellation at the location of the current atom. Numbers in column one can be any positive integer including zero, while column two values will always be greater than zero. Column one data can be used to locate vacancies (the coordinates are given by the atom coordinates at the time step when the compute was first invoked), while column two data can be used to identify interstitial atoms.

If the `neighbors` value is set to yes, then this compute creates a local array with 3 columns. There is one row for each face of each Voronoi cell. The 3 columns are the atom ID of the atom that owns the cell, the atom ID of the atom in the neighboring cell (or zero if the face is external), and the area of the face. The array can be accessed by any command that uses local values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options. More specifically, the array can be accessed by a `dump local` command to write a file containing all the Voronoi neighbors in a system:

```bash
compute 6 all voronoi/atom neighbors yes
```

If the `face_threshold` keyword is used, then only faces with areas greater than the threshold are stored.

The Voronoi calculation is performed by the freely available Voro++ package, written by Chris Rycroft at UC Berkeley and LBL, which must be installed on your system when building LAMMPS for use with this compute. See instructions on obtaining and installing the Voro++ software in the src/VORONOI/README file.

**Note:** The calculation of Voronoi volumes is performed by each processor for the atoms it owns, and includes the effect of ghost atoms stored by the processor. This assumes that the Voronoi cells of owned atoms are not affected by atoms beyond the ghost atom cut-off distance. This is usually a good assumption for liquid and solid systems, but may lead to underestimation of Voronoi volumes in low density systems. By default, the set of ghost atoms stored by each processor is determined by the cutoff used for `pair_style` interactions. The cutoff can be set explicitly via the `comm_modify cutoff` command. The Voronoi cells for atoms adjacent to empty regions will extend into those regions up to the communication cutoff in x, y, or z. In that situation, an exterior face is created at the cutoff distance normal to the x, y, or z direction. For triclinic systems, the exterior face is parallel to the corresponding reciprocal lattice vector.

**Note:** The Voro++ package performs its calculation in 3d. This will still work for a 2d LAMMPS simulation, provided all the atoms have the same z coordinate. The Voronoi cell of each atom will be a columnar polyhedron with constant cross-sectional area along the z direction and two exterior faces at the top and bottom of the simulation box. If the atoms do not all have the same z coordinate, then the columnar cells will be accordingly distorted. The cross-sectional area of each Voronoi cell can be obtained by dividing its volume by the z extent of the simulation box. Note that you define the z extent of the simulation box for 2d simulations when using the `create_box` or `read_data` commands.
19.144.4 Output info

By default, this compute calculates a per-atom array with 2 columns. In regular dynamic tessellation mode the first column is the Voronoi volume, the second is the neighbor count, as described above (read above for the output data in case the occupation keyword is specified). These values can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options. If the peratom keyword is set to “no”, the per-atom array is still created, but it is not accessible.

If the edge_histo keyword is used, then this compute generates a global vector of length maxedge+1, containing a histogram of the number of edges per face.

If the neighbors value is set to yes, then this compute calculates a local array with 3 columns. There is one row for each face of each Voronoi cell.

Note: Some LAMMPS commands such as the compute reduce command can accept either a per-atom or local quantity. If this compute produces both quantities, the command may access the per-atom quantity, even if you want to access the local quantity. This effect can be eliminated by using the peratom keyword to turn off the production of the per-atom quantities. For the default value yes both quantities are produced. For the value no, only the local array is produced.

The Voronoi cell volume will be in distance units cubed. The Voronoi face area will be in distance units squared.

19.144.5 Restrictions

This compute is part of the VORONOI package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

It also requires you have a copy of the Voro++ library built and installed on your system. See instructions on obtaining and installing the Voro++ software in the src/VORONOI/README file.

19.144.6 Related commands

dump custom, dump local

19.144.7 Default

neighbors no, peratom yes

19.145 compute xrd command

19.145.1 Syntax

```
compute ID group-ID xrd lambda type1 type2 ... typeN keyword value ...
```

- ID, group-ID are documented in compute command
- xrd = style name of this compute command
- lambda = wavelength of incident radiation (length units)
- type1 type2 . . . typeN = chemical symbol of each atom type (see valid options below)
• zero or more keyword/value pairs may be appended
• keyword = 2Theta or c or LP or manual or echo

2Theta values = Min2Theta Max2Theta
Min2Theta,Max2Theta = minimum and maximum 2 theta range to explore
(radians or degrees)
c values = c1 c2 c3
c1,c2,c3 = parameters to adjust the spacing of the reciprocal
lattice nodes in the h, k, and l directions respectively
LP value = switch to apply Lorentz-polarization factor
0/1 = off/on
manual = flag to use manual spacing of reciprocal lattice points
based on the values of the c parameters
echo = flag to provide extra output for debugging purposes

19.145.2 Examples

```plaintext
compute 1 all xrd 1.541838 Al O 2Theta 0.087 0.87 c 1 1 1 LP 1 echo
compute 2 all xrd 1.541838 Al O 2Theta 10 100 c 0.05 0.05 0.05 LP 1 manual
fix 1 all ave/histo/weight 1 1 1 0.087 0.87 250 c_1[1] c_1[2] mode vector file Rad2Theta.xrd
fix 2 all ave/histo/weight 1 1 1 10 100 250 c_2[1] c_2[2] mode vector file Deg2Theta.xrd
```

19.145.3 Description

Define a computation that calculates x-ray diffraction intensity as described in (Coleman) on a mesh of reciprocal lattice nodes defined by the entire simulation domain (or manually) using a simulated radiation of wavelength lambda.

The x-ray diffraction intensity, I, at each reciprocal lattice point, k, is computed from the structure factor, F, using the equations:

\[
I = Lp(\theta) \frac{F^* F}{N}
\]

\[
F(k) = \sum_{j=1}^{N} f_j(\theta) \exp(2\pi i k \cdot r_j)
\]

\[
Lp(\theta) = \frac{1 + \cos^2(2\theta)}{\cos(\theta)\sin^2(\theta)}
\]

\[
\sin(\theta) = \frac{|k|}{\lambda}
\]

Here, K is the location of the reciprocal lattice node, r_j is the position of each atom, f_j are atomic scattering factors, Lp is the Lorentz-polarization factor, and \( \theta \) is the scattering angle of diffraction. The Lorentz-polarization factor can be turned off using the optional LP keyword.

Diffraction intensities are calculated on a three-dimensional mesh of reciprocal lattice nodes. The mesh spacing is defined either (a) by the entire simulation domain or (b) manually using selected values as shown in the 2D diagram below.

For a mesh defined by the simulation domain, a rectilinear grid is constructed with spacing \( c*\text{inv}(A) \) along each reciprocal lattice axis. Where A are the vectors corresponding to the edges of the simulation cell. If one or two
directions has non-periodic boundary conditions, then the spacing in these directions is defined from the average of the (inversed) box lengths with periodic boundary conditions. Meshes defined by the simulation domain must contain at least one periodic boundary.

If the manual flag is included, the mesh of reciprocal lattice nodes will defined using the $c$ values for the spacing along each reciprocal lattice axis. Note that manual mapping of the reciprocal space mesh is good for comparing diffraction results from multiple simulations; however it can reduce the likelihood that Bragg reflections will be satisfied unless small spacing parameters (< 0.05 Å$^{-1}$) are implemented. Meshes with manual spacing do not require a periodic boundary.

The limits of the reciprocal lattice mesh are determined by range of scattering angles explored. The 2Theta parameters allows the user to reduce the scattering angle range to only the region of interest which reduces the cost of the computation.

The atomic scattering factors, $f_j$, accounts for the reduction in diffraction intensity due to Compton scattering. Compute xrd uses analytical approximations of the atomic scattering factors that vary for each atom type (type1 type2 … typeN) and angle of diffraction. The analytic approximation is computed using the formula (Colliex):

$$f_j \left( \frac{\sin(\theta)}{\lambda} \right) = \sum_i^4 a_i \exp \left( -b_i \frac{\sin^2(\theta)}{\lambda^2} \right) + c$$

Coefficients parameterized by (Peng) are assigned for each atom type designating the chemical symbol and charge of each atom type. Valid chemical symbols for compute xrd are:

If the *echo* keyword is specified, compute xrd will provide extra reporting information to the screen.

### 19.145.4 Output info

This compute calculates a global array. The number of rows in the array is the number of reciprocal lattice nodes that are explored which by the mesh. The global array has 2 columns.

The first column contains the diffraction angle in the units (radians or degrees) provided with the *2Theta* values. The second column contains the computed diffraction intensities as described above.

The array can be accessed by any command that uses global values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

All array values calculated by this compute are “intensive”.

### 19.145.5 Restrictions

This compute is part of the USER-DIFFRACTION package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

The compute_xrd command does not work for triclinic cells.

### 19.145.6 Related commands

*fix ave/histo, compute saed*

### 19.145.7 Default

The option defaults are 2Theta = 1 179 (degrees), c = 1 1 1, LP = 1, no manual flag, no echo flag.

(Coleman) Coleman, Spearot, Capolungo, MSMSE, 21, 055020 (2013).

20.1 pair_style adp command

Accelerator Variants: adp/omp

20.1.1 Syntax

\texttt{pair_style adp}

20.1.2 Examples

\texttt{pair_style adp}
\texttt{pair_coeff * * Ta.adp Ta}
\texttt{pair_coeff * * ../potentials/AlCu.adp Al Al Cu}

20.1.3 Description

Style \textit{adp} computes pairwise interactions for metals and metal alloys using the angular dependent potential (ADP) of (Mishin), which is a generalization of the \textit{embedded atom method (EAM) potential}. The LAMMPS implementation is discussed in (Singh). The total energy $E_i$ of an atom $I$ is given by

$$E_i = F_\alpha \left( \sum_{j \neq i} \rho_\beta (r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha \beta} (r_{ij}) + \frac{1}{2} \sum_s (\mu_s^i)^2 + \frac{1}{2} \sum_{s,t} (\lambda_{st}^i)^2 - \frac{1}{6} \nu_i^2$$

$$\mu_s^i = \sum_{j \neq i} u_{\alpha \beta} (r_{ij}) r_{ij}^s$$

$$\lambda_{st}^i = \sum_{j \neq i} w_{\alpha \beta} (r_{ij}) r_{ij}^s r_{ij}^t$$

$$\nu_i = \sum_s \lambda_{ss}^i$$

where $F$ is the embedding energy which is a function of the atomic electron density $\rho$, $\phi$ is a pair potential interaction, $\alpha$ and $\beta$ are the element types of atoms $I$ and $J$, and $s$ and $t = 1, 2, 3$ and refer to the cartesian coordinates. The $\mu$ and $\lambda$ terms represent the dipole and quadruple distortions of the local atomic environment which extend the original EAM framework by introducing angular forces.
Note that unlike for other potentials, cutoffs for ADP potentials are not set in the pair_style or pair_coeff command; they are specified in the ADP potential files themselves. Likewise, the ADP potential files list atomic masses; thus you do not need to use the mass command to specify them.

**ADP potentials are available from:**
- The NIST WWW site at [http://www.ctcms.nist.gov/potentials](http://www.ctcms.nist.gov/potentials). Note that ADP potentials obtained from NIST must be converted into the extended DYNAMO setfl format discussed below.
- The OpenKIM Project at [https://openkim.org/browse/models/by-type](https://openkim.org/browse/models/by-type) provides ADP potentials that can be used directly in LAMMPS with the kim_commands interface.

Only a single pair_coeff command is used with the adp style which specifies an extended DYNAMO setfl file, which contains information for $M$ elements. These are mapped to LAMMPS atom types by specifying $N$ additional arguments after the filename in the pair_coeff command, where $N$ is the number of LAMMPS atom types:

- filename
- $N$ element names = mapping of extended setfl elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, the potentials/AlCu.adp file, included in the potentials directory of the LAMMPS distribution, is an extended setfl file which has tabulated ADP values for $w$ elements and their alloy interactions: Cu and Al. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Al, and the fourth to be Cu, you would use the following pair_coeff command:

```
pair_coeff * * AlCu.adp Al Al Al Cu
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Al arguments map LAMMPS atom types 1,2,3 to the Al element in the extended setfl file. The final Cu argument maps LAMMPS atom type 4 to the Al element in the extended setfl file. Note that there is no requirement that your simulation use all the elements specified by the extended setfl file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an adp potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Adp files in the potentials directory of the LAMMPS distribution have an “.adp” suffix. A DYNAMO setfl file extended for ADP is formatted as follows. Basically it is the standard setfl format with additional tabulated functions $u$ and $w$ added to the file after the tabulated pair potentials. See the pair_eam command for further details on the setfl format.

- lines 1,2,3 = comments (ignored)
- line 4: $N_{\text{elements}}$ Element1 Element2 ... ElementN
- line 5: $N_{\rho}$, $d_{\rho}$, $N_{r}$, $d_{r}$, cutoff

Following the 5 header lines are $N_{\text{elements}}$ sections, one for each element, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function $F(\rho)$ ($N_{\rho}$ values)
- density function $\rho(r)$ ($N_{r}$ values)

Following the $N_{\text{elements}}$ sections, $N_{r}$ values for each pair potential $\phi(r)$ array are listed for all $i, j$ element pairs in the same format as other arrays. Since these interactions are symmetric ($i, j = j, i$) only $\phi$ arrays with $i \geq j$ are listed, in the following order:

$$i, j = (1, 1), (2, 1), (2, 2), (3, 1), (3, 2), (3, 3), (4, 1), \ldots, (N_{\text{elements}}, N_{\text{elements}}).$$
The tabulated values for each $\phi$ function are listed as $r \times \phi$ (in units of eV-Angstroms), since they are for atom pairs, the same as for other EAM files.

After the $\phi(r)$ arrays, each of the $u(r)$ arrays are listed in the same order with the same assumptions of symmetry. Directly following the $u(r)$, the $w(r)$ arrays are listed. Note that $\phi(r)$ is the only array tabulated with a scaling by $r$.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.1.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, no special mixing rules are needed, since the ADP potential files specify alloy interactions explicitly.

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 20.1.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package.

### 20.1.6 Related commands

`pair_coeff`, `pair_eam`

### 20.1.7 Default

`none`

20.2 pair_style agni command

Accelerator Variants: agni/omp

20.2.1 Syntax

```
pair_style agni
```

20.2.2 Examples

```
pair_style agni
pair_coeff  *  *  Al.agni Al
```

20.2.3 Description

Style `agni` style computes the many-body vectorial force components for an atom as

\[
F_i^u = \sum_i N_t \alpha_t \cdot \exp \left[ -\frac{(d_{i,t}^u)^2}{2l^2} \right]
\]

\[
d_{i,t}^u = ||V_i^u(\eta) - V_t^u(\eta)||
\]

\[
V_i^u(\eta) = \sum_{j \neq i} \frac{r_{ij}^u}{r_{ij}} \cdot e^{-\left(\frac{di}{\l}\right)^2} \cdot f_d(r_{ij})
\]

\[
f_d(r_{ij}) = \frac{1}{2} \left[ \cos \left( \frac{\pi r_{ij}}{R_c} \right) + 1 \right]
\]

\(u\) labels the individual components, i.e. \(x, y\) or \(z\), and \(V\) is the corresponding atomic fingerprint. \(d\) is the Euclidean distance between any two atomic fingerprints. A total of \(N_t\) reference atomic environments are considered to construct the force field file. \(\alpha_t\) and \(l\) are the weight coefficients and length scale parameter of the non-linear regression model.

The method implements the recently proposed machine learning access to atomic forces as discussed extensively in the following publications - (Botu1) and (Botu2). The premise of the method is to map the atomic environment numerically into a fingerprint, and use machine learning methods to create a mapping to the vectorial atomic forces.

Only a single pair_coeff command is used with the `agni` style which specifies an AGNI potential file containing the parameters of the force field for the needed elements. These are mapped to LAMMPS atom types by specifying \(N\) additional arguments after the filename in the pair_coeff command, where \(N\) is the number of LAMMPS atom types:

- filename
- \(N\) element names = mapping of AGNI elements to atom types

See the `pair_coeff` doc page for alternate ways to specify the path for the force field file.

An AGNI force field is fully specified by the filename which contains the parameters of the force field, i.e., the reference training environments used to construct the machine learning force field. Example force field and input files are provided in the examples/USER/misc/agni directory.

*Styles with omp suffix is functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated style takes the same arguments and should produce the same results, except for round-off and precision issues.*
The accelerated style is part of the USER-OMP. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated style explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.2.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

### 20.2.5 Restrictions

Currently, only elemental systems are implemented. Also, the method only provides access to the forces and not energies or stresses. The lack of potential energy data makes this pair style incompatible with several of the minimizer algorithms like cg or sd. It should work with damped dynamics based minimizers like fire or quickmin. However, one can access the energy via thermodynamic integration of the forces as discussed in \( (Botu3) \). This pair style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The AGNI force field files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the AGNI potential with any LAMMPS units, but you would need to create your own AGNI potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

### 20.2.6 Related commands

pair_coeff

### 20.2.7 Default

none

20.3 pair_style airebo command

Accelerator Variants: airebo/intel, airebo/omp

20.4 pair_style airebo/morse command

Accelerator Variants: airebo/morse/intel, airebo/morse/omp

20.5 pair_style rebo command

Accelerator Variants: rebo/intel, rebo/omp

20.5.1 Syntax

```plaintext
pair_style style cutoff LJ_flag TORSION_flag cutoff_min
```

- style = airebo or airebo/morse or rebo
- cutoff = LJ or Morse cutoff (σ scale factor) (AIREBO and AIREBO-M only)
- LJ_flag = 0/1 to turn off/on the LJ or Morse term (AIREBO and AIREBO-M only, optional)
- TORSION_flag = 0/1 to turn off/on the torsion term (AIREBO and AIREBO-M only, optional)
- cutoff_min = Start of the transition region of cutoff (σ scale factor) (AIREBO and AIREBO-M only, optional)

20.5.2 Examples

```plaintext
pair_style airebo 3.0
pair_style airebo 2.5 1 0
pair_coeff * * ../potentials/CH.airebo H C
pair_style airebo/morse 3.0
pair_coeff * * ../potentials/CH.airebo-m H C
pair_style rebo
pair_coeff * * ../potentials/CH.rebo H C
```

20.5.3 Description

The airebo pair style computes the Adaptive Intermolecular Reactive Empirical Bond Order (AIREBO) Potential of (Stuart) for a system of carbon and/or hydrogen atoms. Note that this is the initial formulation of AIREBO from 2000, not the later formulation.

The airebo/morse pair style computes the AIREBO-M potential, which is equivalent to AIREBO, but replaces the LJ term with a Morse potential. The Morse potentials are parameterized by high-quality quantum chemistry (MP2) calculations and do not diverge as quickly as particle density increases. This allows AIREBO-M to retain accuracy to much higher pressures than AIREBO (up to 40 GPa for Polyethylene). Details for this potential and its parameterization are given in (O’Conner).
The rebo pair style computes the Reactive Empirical Bond Order (REBO) Potential of (Brenner). Note that this is the so-called second generation REBO from 2002, not the original REBO from 1990. As discussed below, second generation REBO is closely related to the initial AIREBO; it is just a subset of the potential energy terms with a few slightly different parameters.

The AIREBO potential consists of three terms:

\[
E = \frac{1}{2} \sum_{i} \sum_{j \neq i} \left[ E_{ij}^{REBO} + E_{ij}^{LJ} + \sum_{k \neq i, j} \sum_{l \neq i, j, k} E_{kijl}^{TORSION} \right]
\]

By default, all three terms are included. For the airebo style, if the first two optional flag arguments to the pair_style command are included, the LJ and torsional terms can be turned off. Note that both or neither of the flags must be included. If both of the LJ an torsional terms are turned off, it becomes the second-generation REBO potential, with a small caveat on the spline fitting procedure mentioned below. This can be specified directly as pair_style rebo with no additional arguments.

The detailed formulas for this potential are given in (Stuart); here we provide only a brief description.

The \(E_{ij}^{REBO}\) term has the same functional form as the hydrocarbon REBO potential developed in (Brenner). The coefficients for \(E_{ij}^{REBO}\) in AIREBO are essentially the same as Brenner’s potential, but a few fitted spline values are slightly different. For most cases the \(E_{ij}^{REBO}\) term in AIREBO will produce the same energies, forces and statistical averages as the original REBO potential from which it was derived. The \(E_{ij}^{REBO}\) term in the AIREBO potential gives the model its reactive capabilities and only describes short-ranged C-C, C-H and H-H interactions (\(r < 2\) Angstroms). These interactions have strong coordination-dependence through a bond order parameter, which adjusts the attraction between the I,J atoms based on the position of other nearby atoms and thus has 3- and 4-body dependence.

The \(E_{ij}^{LJ}\) term adds longer-ranged interactions (\(2 < r < \text{cutoff}\)) using a form similar to the standard Lennard Jones potential. The \(E_{ij}^{LJ}\) term in AIREBO contains a series of switching functions so that the short-ranged LJ repulsion \((1/r^{12})\) does not interfere with the energetics captured by the \(E_{ij}^{REBO}\) term. The extent of the \(E_{ij}^{LJ}\) interactions is determined by the cutoff argument to the pair_style command which is a scale factor. For each type pair (C-C, C-H, H-H) the cutoff is obtained by multiplying the scale factor by the sigma value defined in the potential file for that type pair. In the standard AIREBO potential, \(\sigma_{CC} = 3.4\) Angstroms, so with a scale factor of 3.0 (the argument in pair_style), the resulting \(E_{ij}^{LJ}\) cutoff would be 10.2 Angstroms.

By default, the longer-ranged interaction is smoothly switched off between 2.16 and 3.0 \(\sigma\). By specifying \(\text{cutoff\_min}\) in addition to \(\text{cutoff}\), the switching can be configured to take place between \(\text{cutoff\_min}\) and \(\text{cutoff}\). \(\text{cutoff\_min}\) can only be specified if all optional arguments are given.

The \(E_{kijl}^{TORSION}\) term is an explicit 4-body potential that describes various dihedral angle preferences in hydrocarbon configurations.

Only a single pair_coeff command is used with the airebo, airebo or rebo style which specifies an AIREBO, REBO, or AIREBO-M potential file with parameters for C and H. Note that as of LAMMPS version 15 May 2019 the rebo style in LAMMPS uses its own potential file (CH.rebo). These are mapped to LAMMPS atom types by specifying \(N\) additional arguments after the filename in the pair_coeff command, where \(N\) is the number of LAMMPS atom types:

- \text{filename}
- \text{\(N\) element names} = mapping of AIREBO elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, if your LAMMPS simulation has 4 atom types and you want the first 3 to be C, and the fourth to be H, you would use the following pair_coeff command:

```plaintext
pair_coeff * * CH.airebo C C C H
```
The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three C arguments map LAMMPS atom types 1,2,3 to the C element in the AIREBO file. The final H argument maps LAMMPS atom type 4 to the H element in the SW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a airebo potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The parameters/coefficients for the AIREBO potentials are listed in the CH.airebo file to agree with the original (Stuart) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done cautiously.

Similarly the parameters/coefficients for the AIREBO-M potentials are listed in the CH.airebo-m file to agree with the (O'Connor) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done cautiously. The AIREBO-M Morse potentials were parameterized using a cutoff of 3.0 ($\sigma$). Modifying this cutoff may impact simulation accuracy.

This pair style tallies a breakdown of the total AIREBO potential energy into sub-categories, which can be accessed via the compute pair command as a vector of values of length 3. The 3 values correspond to the following sub-categories:

1. $E_{\text{REBO}}$ = REBO energy
2. $E_{\text{LJ}}$ = Lennard-Jones energy
3. $E_{\text{TORSION}}$ = Torsion energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```plaintext
compute 0 all pair airebo
variable REBO equal c_0[1]
variable LJ equal c_0[2]
variable TORSION equal c_0[3]
thermo_style custom step temp epair v_REBO v_LJ v_TORSION
```

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.5.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support the pair_modify mix, shift, table, and tail options.

These pair styles do not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.
20.5.5 Restrictions

These pair styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair potentials require the newton setting to be “on” for pair interactions.

The CH.airebo and CH.airebo-m potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the AIREBO, AIREBO-M or REBO potential with any LAMMPS units, but you would need to create your own AIREBO or AIREBO-M potential file with coefficients listed in the appropriate units, if your simulation does not use “metal” units.

pair_coeff 1 2 atm 2 0.100
pair_coeff 2 2 atm 2 0.125
20.6.3 Description

The \textit{atm} style computes a 3-body \textit{Axilrod-Teller-Muto} potential for the energy $E$ of a system of atoms as

$$E = \nu \frac{1 + 3 \cos \gamma_1 \cos \gamma_2 \cos \gamma_3}{r_{12}^2 r_{23}^2 r_{31}^2}$$

where $\nu$ is the three-body interaction strength. The distances between pairs of atoms $r_{12}$, $r_{23}$, $r_{31}$ and the angles $\gamma_1$, $\gamma_2$, $\gamma_3$ are as shown in this diagram:

Note that for the interaction between a triplet of atoms $I, J, K$, there is no “central” atom. The interaction is symmetric with respect to permutation of the three atoms. Thus the $\nu$ value is the same for all those permutations of the atom types of $I, J, K$ and needs to be specified only once, as discussed below.

The \textit{atm} potential is typically used in combination with a two-body potential using the \textit{pair_style hybrid/overlay} command as in the example above.

The potential for a triplet of atom is calculated only if all 3 distances $r_{12}$, $r_{23}$, $r_{31}$ between the 3 atoms satisfy $r_{I,J} < \text{cutoff}$. In addition, the product of the 3 distances $r_{12} r_{23} r_{31} < \text{cutoff\_triple}^3$ is required, which excludes from calculation the triplets with small contribution to the interaction.

The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the restart files read by the \textit{read_restart} commands:

- $K =$ atom type of the third atom (1 to $N$ types)
- $\nu =$ prefactor (energy/distance$^9$ units)

$K$ can be specified in one of two ways. An explicit numeric value can be used, as in the second example above. $J \leq K$ is required. LAMMPS sets the coefficients for the other 5 symmetric interactions to the same values. E.g. if $I = 1$, $J = 2$, $K = 3$, then these 6 values are set to the specified $\nu$: $\nu_{123}$, $\nu_{132}$, $\nu_{213}$, $\nu_{231}$, $\nu_{312}$, $\nu_{321}$. This enforces the symmetry discussed above.

A wildcard asterisk can be used for $K$ to set the coefficients for multiple triplets of atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If $N$ equals the number of atom types, then an asterisk with no numeric values means all types from 1 to $N$. A leading asterisk means all types from 1 to $n$ (inclusive). A middle asterisk means all types from $n$ to $N$ (inclusive). A middle asterisk means all types from $m$ to $n$ (inclusive). Note that only type triplets with $J \leq K$ are considered; if asterisks imply type triplets where $K < J$, they are ignored.

Note that a \textit{pair_coeff} command can override a previous setting for the same $I, J, K$ triplet. For example, these commands set $\nu$ for all $I, J, K$ triplets, then overwrite $\nu$ for just the $I, J, K = 2, 3, 4$ triplet:

\begin{verbatim}
pair_coeff * * * 0.25
pair_coeff 2 3 4 0.1
\end{verbatim}

Note that for a simulation with a single atom type, only a single entry is required, e.g.

\begin{verbatim}
pair_coeff 1 1 1 0.25
\end{verbatim}

For a simulation with two atom types, four \textit{pair_coeff} commands will specify all possible $\nu$ values:
For a simulation with three atom types, ten pair_coeff commands will specify all possible nu values:

```
pair_coeff 1 1 1 nu1
pair_coeff 1 1 2 nu2
pair_coeff 1 2 2 nu3
pair_coeff 2 2 2 nu4
pair_coeff 1 1 3 nu5
pair_coeff 1 2 3 nu6
pair_coeff 1 3 3 nu7
pair_coeff 2 2 3 nu8
pair_coeff 2 3 3 nu9
pair_coeff 3 3 3 nu10
```

By default the \( \nu \) value for all triplets is set to 0.0. Thus it is not required to provide pair_coeff commands that enumerate triplet interactions for all \( K \) types. If some \( I,J,K \) combination is not specified, then there will be no 3-body ATM interactions for that combination and all its permutations. However, as with all pair styles, it is required to specify a pair_coeff command for all \( I,J \) combinations, else an error will result.

### 20.6.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair styles do not support the pair_modify mix, shift, table, and tail options.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. However, if the atm potential is used in combination with other potentials using the pair_style hybrid/overlay command then pair_coeff commands need to be re-specified in the restart input script.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

### 20.6.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.7 pair_style awpmd/cut command

20.7.1 Syntax

```
pair_style awpmd/cut Rc keyword value ...
```

- \( Rc \) = global cutoff, -1 means cutoff of half the shortest box length
- zero or more keyword/value pairs may be appended
- keyword = \{\text{hartree} or \text{dproduct} or \text{uhf} or \text{free} or \text{pbc} or \text{fix} or \text{harm} or \text{ermscale} or \text{flex_press}\)

  - \text{hartree} value = none
  - \text{dproduct} value = none
  - \text{uhf} value = none
  - \text{free} value = none
  - \text{pbc} value = Plen
    - \(\text{Plen} = \text{periodic width of electron} = -1 \text{ or positive value (distance units)}\)
  - \text{fix} value = Flen
    - \(\text{Flen} = \text{fixed width of electron} = -1 \text{ or positive value (distance units)}\)
  - \text{harm} value = width
    - \(\text{width} = \text{harmonic width constraint}\)
  - \text{ermscale} value = factor
    - \(\text{factor} = \text{scaling between electron mass and width variable mass}\)
  - \text{flex_press} value = none

20.7.2 Examples

```
pair_style awpmd/cut -1
pair_style awpmd/cut 40.0 uhf free
pair_coeff * *
pair_coeff 2 2 20.0
```

20.7.3 Description

This pair style contains an implementation of the Antisymmetrized Wave Packet Molecular Dynamics (AWPMD) method. Need citation here. Need basic formulas here. Could be links to other documents.

\( Rc \) is the cutoff.

The \text{pair_style} command allows for several optional keywords to be specified.

The \text{hartree}, \text{dproduct}, and \text{uhf} keywords specify the form of the initial trial wave function for the system. If the \text{hartree} keyword is used, then a Hartree multielectron trial wave function is used. If the \text{dproduct} keyword is used,
then a trial function which is a product of two determinants for each spin type is used. If the uhf keyword is used, then an unrestricted Hartree-Fock trial wave function is used.

The free, pbc, and fix keywords specify a width constraint on the electron wave packets. If the free keyword is specified, then there is no constraint. If the pbc keyword is used and Plen is specified as -1, then the maximum width is half the shortest box length. If Plen is a positive value, then the value is the maximum width. If the fix keyword is used and Flen is specified as -1, then electrons have a constant width that is read from the data file. If Flen is a positive value, then the constant width for all electrons is set to Flen.

The harm keyword allows oscillations in the width of the electron wave packets. More details are needed.

The ermscale keyword specifies a unitless scaling factor between the electron masses and the width variable mass. More details needed.

If the flex_press keyword is used, then a contribution from the electrons is added to the total virial and pressure of the system.

This potential is designed to be used with atom_style wavepacket definitions, in order to handle the description of systems with interacting nuclei and explicit electrons.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- cutoff (distance units)

For awpmd/cut, the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the pair_style command is used.

### 20.7.4 Mixing, shift, table, tail correction, restart, rRESPA info

The pair_modify mix, shift, table, and tail options are not relevant for this pair style.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

### 20.7.5 Restrictions

20.8 pair_style beck command

Accelerator Variants: beck/gpu, beck/omp

20.8.1 Syntax

```
pair_style beck Rc
```

- Rc = cutoff for interactions (distance units)

20.8.2 Examples

```
pair_style beck 8.0
pair_coeff * * 399.671876712 0.0000867636112694 0.675 4.390 0.0003746
pair_coeff 1 1 399.671876712 0.0000867636112694 0.675 4.390 0.0003746 6.0
```

20.8.3 Description

Style beck computes interactions based on the potential by (Beck), originally designed for simulation of Helium. It includes truncation at a cutoff distance Rc.

\[
E(r) = A \exp\left[-\alpha r - \beta r^6\right] - \frac{B}{(r^2 + a^2)^{3/2}} \left(1 + \frac{2.709 + 3a^2}{r^2 + a^2}\right) \quad r < R_c
\]

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands.

- A (energy units)
- B (energy-distance^6 units)
- a (distance units)
- \(\alpha\) (1/distance units)
- \(\beta\) (1/distance^6 units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff \(R_c\) is used.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.8.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, coefficients must be specified. No default mixing rules are used. This pair style does not support the pair_modify shift option for the energy of the pair interaction. The pair_modify table option is not relevant for this pair style. This pair style does not support the pair_modify tail option for adding long-range tail corrections. This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.9 pair_style body/nparticle command

20.9.1 Syntax

```
pair_style body/nparticle cutoff
```

cutoff = global cutoff for interactions (distance units)
20.9.2 Examples

```plaintext
pair_style body/nparticle 3.0
pair_coeff * * 1.0 1.0
pair_coeff 1 1 1.0 1.5 2.5
```

20.9.3 Description

Style body/nparticle is for use with body particles and calculates pairwise body/body interactions as well as interactions between body and point-particles. See the Howto body doc page for more details on using body particles.

This pair style is designed for use with the “nparticle” body style, which is specified as an argument to the “atom-style body” command. See the Howto body doc page for more details about the body styles LAMMPS supports. The “nparticle” style treats a body particle as a rigid body composed of N sub-particles.

The coordinates of a body particle are its center-of-mass (COM). If the COMs of a pair of body particles are within the cutoff (global or type-specific, as specified above), then all interactions between pairs of sub-particles in the two body particles are computed. E.g. if the first body particle has 3 sub-particles, and the second has 10, then 30 interactions are computed and summed to yield the total force and torque on each body particle.

Note: In the example just described, all 30 interactions are computed even if the distance between a particular pair of sub-particles is greater than the cutoff. Likewise, no interaction between two body particles is computed if the two COMs are further apart than the cutoff, even if the distance between some pairs of their sub-particles is within the cutoff. Thus care should be used in defining the cutoff distances for body particles, depending on their shape and size.

Similar rules apply for a body particle interacting with a point particle. The distance between the two particles is calculated using the COM of the body particle and the position of the point particle. If the distance is within the cutoff and the body particle has N sub-particles, then N interactions with the point particle are computed and summed. If the distance is not within the cutoff, no interactions between the body and point particle are computed.

The interaction between two sub-particles, or a sub-particle and point particle, or between two point particles is computed as a Lennard-Jones interaction, using the standard formula

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \quad r < R_c \]

where \( R_c \) is the cutoff. As explained above, an interaction involving one or two body sub-particles may be computed even for \( r > R_c \).

For style body, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.
20.9.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of this pair style can be mixed. The default mix value is geometric. See the pair_modify command for details.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.9.5 Restrictions

This style is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Defining particles to be bodies so they participate in body/body or body/particle interactions requires the use of the atom_style body command.

20.9.6 Related commands

pair_coeff, fix rigid

20.10 pair_style body/rounded/polygon command

20.10.1 Syntax

```
pair_style body/rounded/polygon c_n c_t mu delta_ua cutoff
```

c_n = normal damping coefficient
c_t = tangential damping coefficient
mu = normal friction coefficient during gross sliding
delta_ua = multiple contact scaling factor
cutoff = global separation cutoff for interactions (distance units), see below for --definition
20.10.2 Examples

```
pair_style  body/rounded/polygon 20.0 5.0 0.0 1.0 0.5
pair_coeff  *  *  100.0  1.0
pair_coeff  1 1 100.0  1.0
```

20.10.3 Description

Style `body/rounded/polygon` is for use with 2d models of body particles of style `rounded/polygon`. It calculates pairwise body/body interactions which can include body particles modeled as 1-vertex circular disks with a specified diameter. See the Howto body doc page for more details on using body rounded/polygon particles.

This pairwise interaction between rounded polygons is described in *Fraige*, where a polygon does not have sharp corners, but is rounded at its vertices by circles centered on each vertex with a specified diameter. The edges of the polygon are defined between pairs of adjacent vertices. The circle diameter for each polygon is specified in the data file read by the `read data` command. This is a 2d discrete element model (DEM) which allows for multiple contact points.

Note that when two particles interact, the effective surface of each polygon particle is displaced outward from each of its vertices and edges by half its circle diameter (as in the diagram below of a gray and yellow square particle). The interaction forces and energies between two particles are defined with respect to the separation of their respective rounded surfaces, not by the separation of the vertices and edges themselves.

This means that the specified cutoff in the pair_style command is the cutoff distance, $r_c$, for the surface separation, $\delta_n$ (see figure below). This is the distance at which two particles no longer interact. If $r_c$ is specified as 0.0, then it is a contact-only interaction. I.e. the two particles must overlap in order to exert a repulsive force on each other. If $r_c > 0.0$, then the force between two particles will be attractive for surface separations from 0 to $r_c$, and repulsive once the particles overlap.

Note that unlike for other pair styles, the specified cutoff is not the distance between the centers of two particles at which they stop interacting. This center-to-center distance depends on the shape and size of the two particles and their relative orientation. LAMMPS takes that into account when computing the surface separation distance and applying the $r_c$ cutoff.

The forces between vertex-vertex, vertex-edge, and edge-edge overlaps are given by:

\[
F_n = \begin{cases} 
  k_n \delta_n - c_n v_n & \delta_n \leq 0 \\
  -k_{na} \delta_n - c_n v_n & 0 < \delta_n \leq r_c \\
  0 & \delta_n > r_c 
\end{cases}
\]

\[
F_t = \begin{cases} 
  \mu k_n \delta_n - c_t v_t & \delta_n \leq 0 \\
  0 & \delta_n > 0 
\end{cases}
\]
Note that $F_n$ and $F_t$ are functions of the surface separation $\delta_n = d - (R_i + R_j)$. In this model, when $(R_i + R_j) < d < (R_i + R_j) + r_c$, that is, $0 < \delta_n < r_c$, the cohesive region of the two surfaces overlap and the two surfaces are attractive to each other.

In *Fraige*, the tangential friction force between two particles that are in contact is modeled differently prior to gross sliding (i.e. static friction) and during gross-sliding (kinetic friction). The latter takes place when the tangential deformation exceeds the Coulomb frictional limit. In the current implementation, however, we do not take into account frictional history, i.e. we do not keep track of how many time steps the two particles have been in contact nor calculate the tangential deformation. Instead, we assume that gross sliding takes place as soon as two particles are in contact.

The following coefficients must be defined for each pair of atom types via the *pair_coeff* command as in the examples above, or in the data file read by the *read_data* command:

- $k_n$ (energy/distance$^2$ units)
- $k_{na}$ (energy/distance$^2$ units)
Effectively, $k_n$ and $k_{na}$ are the slopes of the red lines in the plot above for force versus surface separation, for $\delta_n < 0$ and $0 < \delta_n < r_c$ respectively.

### 20.10.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to binary restart files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 20.10.5 Restrictions

These pair styles are part of the BODY package. They are only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

### 20.10.6 Related commands

`pair_coeff`

### 20.10.7 Default

none

### 20.11 pair_style body/rounded/polyhedron command

#### 20.11.1 Syntax

```plaintext
pair_style body/rounded/polyhedron c_n c_t mu delta ua cutoff
```

- `c_n` = normal damping coefficient
- `c_t` = tangential damping coefficient
- `mu` = normal friction coefficient during gross sliding
- `delta ua` = multiple contact scaling factor
- `cutoff` = global separation cutoff for interactions (distance units), see below for `--definition`
20.11.2 Examples

```
pair_style body/rounded/polyhedron 20.0 5.0 0.0 1.0 0.5
pair_coeff * * 100.0 1.0
pair_coeff 1 1 100.0 1.0
```

20.11.3 Description

Style `body/rounded/polygon` is for use with 3d models of body particles of style `rounded/polyhedron`. It calculates pairwise body/body interactions which can include body particles modeled as 1-vertex spheres with a specified diameter. See the `Howto body` doc page for more details on using body rounded/polyhedron particles.

This pairwise interaction between the rounded polyhedra is described in Wang, where a polyhedron does not have sharp corners and edges, but is rounded at its vertices and edges by spheres centered on each vertex with a specified diameter. The edges if the polyhedron are defined between pairs of adjacent vertices. Its faces are defined by a loop of edges. The sphere diameter for each polygon is specified in the data file read by the `read_data` command. This is a discrete element model (DEM) which allows for multiple contact points.

Note that when two particles interact, the effective surface of each polyhedron particle is displaced outward from each of its vertices, edges, and faces by half its sphere diameter. The interaction forces and energies between two particles are defined with respect to the separation of their respective rounded surfaces, not by the separation of the vertices, edges, and faces themselves.

This means that the specified cutoff in the pair_style command is the cutoff distance, $r_c$, for the surface separation, $\delta_n$ (see figure below). This is the distance at which two particles no longer interact. If $r_c$ is specified as 0.0, then it is a contact-only interaction. I.e. the two particles must overlap in order to exert a repulsive force on each other. If $r_c > 0.0$, then the force between two particles will be attractive for surface separations from 0 to $r_c$, and repulsive once the particles overlap.

Note that unlike for other pair styles, the specified cutoff is not the distance between the centers of two particles at which they stop interacting. This center-to-center distance depends on the shape and size of the two particles and their relative orientation. LAMMPS takes that into account when computing the surface separation distance and applying the $r_c$ cutoff.

The forces between vertex-vertex, vertex-edge, vertex-face, edge-edge, and edge-face overlaps are given by:

$$
F_n = \begin{cases} 
  k_n \delta_n - c_n v_n, & \delta_n \leq 0 \\
  -k_{na} \delta_n - c_n v_n, & 0 < \delta_n \leq r_c \\
  0, & \delta_n > r_c 
\end{cases}
$$

$$
F_t = \begin{cases} 
  \mu k_n \delta_n - c_t v_t, & \delta_n \leq 0 \\
  0, & \delta_n > 0 
\end{cases}
$$
In *Wang*, the tangential friction force between two particles that are in contact is modeled differently prior to gross sliding (i.e., static friction) and during gross-sliding (kinetic friction). The latter takes place when the tangential deformation exceeds the Coulomb frictional limit. In the current implementation, however, we do not take into account frictional history, i.e., we do not keep track of how many time steps the two particles have been in contact nor calculate the tangential deformation. Instead, we assume that gross sliding takes place as soon as two particles are in contact.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file read by the `read_data` command:

- \( k_n \) (energy/distance\(^2\) units)
- \( k_{na} \) (energy/distance\(^2\) units)

Effectively, \( k_n \) and \( k_{na} \) are the slopes of the red lines in the plot above for force versus surface separation, for \( \delta_n < 0 \) and \( 0 < \delta_n < r_c \) respectively.
20.11.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write its information to binary restart files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.11.5 Restrictions

These pair styles are part of the BODY package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

pair_style bop save
pair_coeff * * ../potentials/CdTe.bop.table Cd Te Te
comm_modify cutoff 14.70
```
20.12.3 Description

The *bop* pair style computes Bond-Order Potentials (BOP) based on quantum mechanical theory incorporating both \( \sigma \) and \( \pi \) bonding. By analytically deriving the BOP from quantum mechanical theory its transferability to different phases can approach that of quantum mechanical methods. This potential is similar to the original BOP developed by Pettifor ([Pettifor_1, Pettifor_2, Pettifor_3]) and later updated by Murdick, Zhou, and Ward ([Murdick, Ward]). Currently, BOP potential files for these systems are provided with LAMMPS: AlCu, CCu, CdTe, CdTeSe, CdZnTe, CuH, GaAs. A system with only a subset of these elements, including a single element (e.g. C or Cu or Al or Ga or Zn or CdZn), can also be modeled by using the appropriate alloy file and assigning all atom types to the single element or subset of elements via the pair_coeff command, as discussed below.

The BOP potential consists of three terms:

\[
E = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} \phi_{ij}(r_{ij}) - \sum_{i=1}^{N} \sum_{j=1}^{N} \beta_{\sigma,ij}(r_{ij}) \cdot \Theta_{\sigma,ij} - \sum_{i=1}^{N} \sum_{j=1}^{N} \beta_{\pi,ij}(r_{ij}) \cdot \Theta_{\pi,ij} + U_{prom}
\]

where \( \phi_{ij}(r_{ij}) \) is a short-range two-body function representing the repulsion between a pair of ion cores, \( \beta_{\sigma,ij}(r_{ij}) \) and \( \beta_{\pi,ij}(r_{ij}) \) are respectively sigma and \( \pi \) bond integrals, \( \Theta_{\sigma,ij} \) and \( \Theta_{\pi,ij} \) are \( \sigma \) and \( \pi \) bond-orders, and \( U_{prom} \) is the promotion energy for sp-valent systems.

The detailed formulas for this potential are given in Ward ([Ward]); here we provide only a brief description.

The repulsive energy \( \phi_{ij}(r_{ij}) \) and the bond integrals \( \beta_{\sigma,ij}(r_{ij}) \) and \( \beta_{\pi,ij}(r_{ij}) \) are functions of the interatomic distance \( r_{ij} \) between atom \( i \) and \( j \). Each of these potentials has a smooth cutoff at a radius of \( r_{cut,ij} \). These smooth cutoffs ensure stable behavior at situations with high sampling near the cutoff such as melts and surfaces.

The bond-orders can be viewed as environment-dependent local variables that are \( ij \) bond specific. The maximum value of the \( \sigma \) bond-order (\( \Theta_{\sigma} \)) is 1, while that of the \( \pi \) bond-order (\( \Theta_{\pi} \)) is 2, attributing to a maximum value of the total bond-order (\( \Theta_{\sigma} + \Theta_{\pi} \)) of 3. The \( \sigma \) and \( \pi \) bond-orders reflect the ubiquitous single-, double-, and triple- bond behavior of chemistry. Their analytical expressions can be derived from tight-binding theory by recursively expanding an inter-site Green’s function as a continued fraction. To accurately represent the bonding with a computationally efficient potential formulation suitable for MD simulations, the derived BOP only takes (and retains) the first two levels of the recursive representations for both the \( \sigma \) and the \( \pi \) bond-orders. Bond-order terms can be understood in terms of molecular orbital hopping paths based upon the Cyrot-Lackmann theorem ([Pettifor_1]). The \( \pi \) bond-order with a half-full valence shell is used to interpolate the bond-order expression that incorporated explicit valance band filling. This \( \pi \) bond-order expression also contains also contains a three-member ring term that allows implementation of an asymmetric density of states, which helps to either stabilize or destabilize close-packed structures. The \( \pi \) bond-order includes hopping paths of length 4. This enables the incorporation of dihedral angles effects.

**Note:** Note that unlike for other potentials, cutoffs for BOP potentials are not set in the pair_style or pair_coeff command; they are specified in the BOP potential files themselves. Likewise, the BOP potential files list atomic masses; thus you do not need to use the mass command to specify them. Note that for BOP potentials with hydrogen, you will likely want to set the mass of H atoms to be 10x or 20x larger to avoid having to use a tiny timestep. You can do this by using the mass command after using the pair_coeff command to read the BOP potential file.

One option can be specified as a keyword with the pair_style command.

The save keyword gives you the option to calculate in advance and store a set of distances, angles, and derivatives of angles. The default is to not do this, but to calculate them on-the-fly each time they are needed. The former may be faster, but takes more memory. The latter requires less memory, but may be slower. It is best to test this option to optimize the speed of BOP for your particular system configuration.

Only a single pair_coeff command is used with the *bop* style which specifies a BOP potential file, with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:
• filename
• N element names = mapping of BOP elements to atom types

As an example, imagine the CdTe.bop file has BOP values for Cd and Te. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Cd, and the fourth to be Te, you would use the following pair_coeff command:

```
pair_coeff  *  *  CdTe  Cd  Cd  Cd  Te
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Cd arguments map LAMMPS atom types 1,2,3 to the Cd element in the BOP file. The final Te argument maps LAMMPS atom type 4 to the Te element in the BOP file.

BOP files in the potentials directory of the LAMMPS distribution have a “.bop” suffix. The potentials are in tabulated form containing pre-tabulated pair functions for $\phi_{ij}(r_{ij})$, $\beta_{\sigma}(r_{ij})$, and $\beta_{\pi}(r_{ij})$.

The parameters/coefficients format for the different kinds of BOP files are given below with variables matching the formulation of Ward ([Ward](#)) and Zhou ([Zhou](#)). Each header line containing a “:” is preceded by a blank line.

---

**No angular table file format:**

The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of g is given below with variables matching the formulation of Ward ([Ward](#)). This format also assumes the angular functions have the formulation of ([Ward](#)).

- Line 1: # elements N

The first line is followed by N lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1: nr, nBOt (nr is the number of divisions the radius is broken into for function tables and MUST be a factor of 5; nBOt is the number of divisions for the tabulated values of $\Theta_{S,ij}$)
- Line 2: delta_1-delta_7 (if all are not used in the particular formulation, set unused values to 0.0)

Following this N lines for e_1-e_N containing p_pi.

- Line 3: p_pi (for e_1)
- Line 4: p_pi (for e_2 and continues to e_N)

The next section contains several pair constants for the number of interaction types e_i-e_j, with i=1->N, j=i->N

- Line 1: r_cut (for e_1-e_1 interactions)
- Line 2: c_sigma, a_sigma, c_pi, a_pi
- Line 3: d_sigma, d_pi
- Line 4: f_sigma, k_sigma, delta_3 (This delta_3 is similar to that of the previous section but is interaction type dependent)

The next section contains a line for each three body interaction type e_j-e_i-e_k with i=0->N, j=0->N, k=j->N

- Line 1: g_(sigma0), g_(sigma1), g_(sigma2) (These are coefficients for g_(sigma,jik)(THETA_(jik)) for e_1-e_1-e_1 interaction. Ward contains the full expressions for the constants as functions of b_(sigma,jik), p_(sigma,jik), u_(sigma,jik))
- Line 2: g_(sigma0), g_(sigma1), g_(sigma2) (for e_1-e_1-e_2)

The next section contains a block for each interaction type for the $\phi_{ij}(r_{ij})$. Each block has nr entries with 5 entries per line.
- Line 1: \( \phi(r_1), \phi(r_2), \phi(r_3), \phi(r_4), \phi(r_5) \) (for the \( e_1-e_1 \) interaction type)
- Line 2: \( \phi(r_6), \phi(r_7), \phi(r_8), \phi(r_9), \phi(r_{10}) \) (this continues until \( nr \))
- ... 
- Line \( nr/5 \_1 \): \( \phi(r_1), \phi(r_2), \phi(r_3), \phi(r_4), \phi(r_5) \), (for the \( e_1-e_1 \) interaction type)

The next section contains a block for each interaction type for the \( \beta_\sigma(r_{ij}) \). Each block has \( nr \) entries with 5 entries per line.
- Line 1: \( \beta_\sigma(r_1), \beta_\sigma(r_2), \beta_\sigma(r_3), \beta_\sigma(r_4), \beta_\sigma(r_5) \) (for the \( e_1-e_1 \) interaction type)
- Line 2: \( \beta_\sigma(r_6), \beta_\sigma(r_7), \beta_\sigma(r_8), \beta_\sigma(r_9), \beta_\sigma(r_{10}) \) (this continues until \( nr \))
- ... 
- Line \( nr/5+1 \): \( \beta_\sigma(r_1), \beta_\sigma(r_2), \beta_\sigma(r_3), \beta_\sigma(r_4), \beta_\sigma(r_5) \) (for the \( e_1-e_2 \) interaction type)

The next section contains a block for each interaction type for \( \beta_\pi(r_{ij}) \). Each block has \( nr \) entries with 5 entries per line.
- Line 1: \( \beta_\pi(r_1), \beta_\pi(r_2), \beta_\pi(r_3), \beta_\pi(r_4), \beta_\pi(r_5) \) (for the \( e_1-e_1 \) interaction type)
- Line 2: \( \beta_\pi(r_6), \beta_\pi(r_7), \beta_\pi(r_8), \beta_\pi(r_9), \beta_\pi(r_{10}) \) (this continues until \( nr \))
- ... 
- Line \( nr/5+1 \): \( \beta_\pi(r_1), \beta_\pi(r_2), \beta_\pi(r_3), \beta_\pi(r_4), \beta_\pi(r_5) \) (for the \( e_1-e_2 \) interaction type)

The next section contains a block for each interaction type for \( \Theta_\sigma(r_{ij})((\Theta_\sigma(r_{ij}))^{1/2}, f_\sigma(r_{ij})) \). Each block has \( nBOt \) entries with 5 entries per line.
- Line 1: \( \Theta_\sigma(r_1), \Theta_\sigma(r_2), \Theta_\sigma(r_3), \Theta_\sigma(r_4), \Theta_\sigma(r_5) \) (for the \( e_1-e_2 \) interaction type)
- Line 2: \( \Theta_\sigma(r_6), \Theta_\sigma(r_7), \Theta_\sigma(r_8), \Theta_\sigma(r_9), \Theta_\sigma(r_{10}) \) (this continues until \( nBOt \))
- ... 
- Line \( nBOt/5+1 \): \( \Theta_\sigma(r_1), \Theta_\sigma(r_2), \Theta_\sigma(r_3), \Theta_\sigma(r_4), \Theta_\sigma(r_5) \) (for the \( e_1-e_2 \) interaction type)

The next section contains a block of \( N \) lines for \( e_1-e_N \)
- Line 1: \( \delta^{\mu} \) (for \( e_1 \))
- Line 2: \( \delta^{\mu} \) (for \( e_2 \) and repeats to \( e_N \))

The last section contains more constants for \( e_i-e_j \) interactions with \( i=0->N, j=i->N \)
- Line 1: \( (A_{ij})^{(\mu*nu)} \) (for \( e_1-e_1 \))
- Line 2: \( (A_{ij})^{(\mu*nu)} \) (for \( e_1-e_2 \) and repeats as above)

Angular spline table file format:
The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of \( g \) is given below with variables matching the formulation of Ward (\textit{Ward}). This format also assumes the angular functions have the formulation of (\textit{Zhou}).
- Line 1: \# elements \( N \)
The first line is followed by N lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1: nr, ntheta, nBOt (nr is the number of divisions the radius is broken into for function tables and MUST be a factor of 5; ntheta is the number of divisions for the tabulated values of the THETA_(S,ij) function)
- Line 2: delta_1-delta_7 (if all are not used in the particular formulation, set unused values to 0.0)

Following this N lines for e_1-e_N containing p_pi.

- Line 3: p_pi (for e_1)
- Line 4: p_pi (for e_2 and continues to e_N)

The next section contains several pair constants for the number of interaction types e_i-e_j, with i=1->N, j=i->N

- Line 1: r_cut (for e_1-e_1 interactions)
- Line 2: c_sigma, a_sigma, c_pi, a_pi
- Line 3: delta_sigma, delta_pi
- Line 4: f_sigma, k_sigma, delta_3 (This delta_3 is similar to that of the previous section but is interaction type dependent)

The next section contains a line for each three body interaction type e_j-e_i-e_k with i=0->N, j=0->N, k=j->N

- Line 1: g0, g1, g2... (These are coefficients for the angular spline of the g_(sigma,jik)(THETA_ijk) for e_1-e_1-e_1 interaction. The function can contain up to 10 term thus 10 constants. The first line can contain up to five constants. If the spline has more than five terms the second line will contain the remaining constants The following lines will then contain the constants for the remaining g0, g1, g2... for e_1-e_1-e_2 and the other three body interactions

The rest of the table has the same structure as the previous section (see above).

Angular no-spline table file format:

The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of g is given below with variables matching the formulation of Ward (Ward). This format also assumes the angular functions have the formulation of (Zhou).

- Line 1: # elements N

The first two lines are followed by N lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1: nr, ntheta, nBOt (nr is the number of divisions the radius is broken into for function tables and MUST be a factor of 5; ntheta is the number of divisions for the tabulated values of the g angular function; nBOt is the number of divisions for the tabulated values of the THETA_(S,ij) function)
- Line 2: delta_1-delta_7 (if all are not used in the particular formulation, set unused values to 0.0)

Following this N lines for e_1-e_N containing p_pi.

- Line 3: p_pi (for e_1)
- Line 4: p_pi (for e_2 and continues to e_N)

The next section contains several pair constants for the number of interaction types e_i-e_j, with i=1->N, j=i->N
The next section contains a line for each three body interaction type e_j-e_i-e_k with i=0->N, j=0->N, k=j->N

- Line 1: g(theta1), g(theta2), g(theta3), g(theta4), g(theta5) (for the e_1-e_1-e_1 interaction type)
- Line 2: g(theta6), g(theta7), g(theta8), g(theta9), g(theta10) (this continues until ntheta)

... 

- Line ntheta/5+1: g(theta1), g(theta2), g(theta3), g(theta4), g(theta5), (for the e_1-e_1-e_2 interaction type)

The rest of the table has the same structure as the previous section (see above).

---

### 20.12.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

---

### 20.12.5 Restrictions

These pair styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair potentials require the `newtion` setting to be “on” for pair interactions.

The CdTe.bop and GaAs.bop potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the BOP potential with any LAMMPS units, but you would need to create your own BOP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

---

20.17.3 Description

The born style computes the Born-Mayer-Huggins or Tosi/Fumi potential described in (Fumi and Tosi), given by

\[ E = A \exp \left( \frac{\sigma - r}{\rho} \right) - \frac{C}{r^6} + \frac{D}{r^8} \quad r < r_c \]

where \( \sigma \) is an interaction-dependent length parameter, \( \rho \) is an ionic-pair dependent length parameter, and \( r_c \) is the cutoff.

The styles with coul/long or coul/msm add a Coulombic term as described for the lj/cut pair styles. An additional damping factor is applied to the Coulombic term so it can be used in conjunction with the kspace_style command and its ewald or ppm of msm option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

If one cutoff is specified for the born/coul/long and born/coul/msm style, it is used for both the A,C,D and Coulombic terms. If two cutoffs are specified, the first is used as the cutoff for the A,C,D terms, and the second is the cutoff for the Coulombic term.

The born/coul/wolf style adds a Coulombic term as described for the Wolf potential in the coul/wolf pair style.

The born/coul/dsf style computes the Coulomb contribution with the damped shifted force model as in the coul/dsf style.

Note that these potentials are related to the Buckingham potential.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- A (energy units)
- \( \rho \) (distance units)
- \( \sigma \) (distance units)
- C (energy units \( \times \) distance units\(^6\))
- D (energy units \( \times \) distance units\(^8\))
- cutoff (distance units)

The second coefficient, rho, must be greater than zero.

The last coefficient is optional. If not specified, the global A,C,D cutoff specified in the pair_style command is used.

For born/coul/long, born/coul/wolf and born/coul/dsf no Coulombic cutoff can be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
20.17.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

These styles support the \textit{pair\_modify} shift option for the energy of the \textit{exp()}, 1/r^6, and 1/r^8 portion of the pair interaction.

The \textit{born/coul/long} pair style supports the \textit{pair\_modify} table option to tabulate the short-range portion of the long-range Coulombic interaction.

These styles support the \textit{pair\_modify} tail option for adding long-range tail corrections to energy and pressure.

These styles writes their information to binary \textit{restart} files, so \textit{pair\_style} and \textit{pair\_coeff} commands do not need to be specified in an input script that reads a restart file.

These styles can only be used via the \textit{pair} keyword of the \textit{run\_style respa} command. They do not support the \textit{inner, middle, outer} keywords.

20.17.5 Restrictions

The \textit{born/coul/long} style is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

20.17.6 Related commands

\textit{pair\_coeff}, \textit{pair\_style buck}

20.17.7 Default

\texttt{none}

20.18 \textit{pair\_style brownian} command

Accelerator Variants: \textit{brownian/omp}

20.19 \textit{pair\_style brownian/poly} command

Accelerator Variants: \textit{brownian/poly/omp}
20.19.1 Syntax

```
pair_style style mu flaglog flagfld cutinner cutoff t_target seed flagHI flagVF
```

- `style` = `brownian` or `brownian/poly`
- `mu` = dynamic viscosity (dynamic viscosity units)
- `flaglog` = 0/1 log terms in the lubrication approximation on/off
- `flagfld` = 0/1 to include/exclude Fast Lubrication Dynamics effects
- `cutinner` = inner cutoff distance (distance units)
- `cutoff` = outer cutoff for interactions (distance units)
- `t_target` = target temp of the system (temperature units)
- `seed` = seed for the random number generator (positive integer)
- `flagHI` (optional) = 0/1 to include/exclude 1/r hydrodynamic interactions
- `flagVF` (optional) = 0/1 to include/exclude volume fraction corrections in the long-range isotropic terms

20.19.2 Examples

```
pair_style brownian 1.5 1 1 2.01 2.5 2.0 5878567 (assuming radius = 1)
pair_coeff 1 1 2.05 2.8
pair_coeff * *
```

20.19.3 Description

Styles `brownian` and `brownian/poly` compute Brownian forces and torques on finite-size spherical particles. The former requires monodisperse spherical particles; the latter allows for polydisperse spherical particles.

These pair styles are designed to be used with either the `pair_style lubricate` or `pair_style lubricateU` commands to provide thermostatting when dissipative lubrication forces are acting. Thus the parameters `mu`, `flaglog`, `flagfld`, `cutinner`, and `cutoff` should be specified consistent with the settings in the lubrication pair styles. For details, refer to either of the lubrication pair styles.

The `t_target` setting is used to specify the target temperature of the system. The random number `seed` is used to generate random numbers for the thermostatting procedure.

The `flagHI` and `flagVF` settings are optional. Neither should be used, or both must be defined.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- `cutinner` (distance units)
- `cutoff` (distance units)

The two coefficients are optional. If neither is specified, the two cutoffs specified in the pair_style command are used. Otherwise both must be specified.
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.19.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I ≠ J, the two cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the `pair_modify` shift option for the energy of the pair interaction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 20.19.5 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Only spherical monodisperse particles are allowed for pair_style brownian.

Only spherical particles are allowed for pair_style brownian/poly.

20.23.3 Description

The buck style computes a Buckingham potential (exp/6 instead of Lennard-Jones 12/6) given by

\[ E = A e^{-r/\rho} - \frac{C}{r^6} \quad r < r_c \]

where \( \rho \) is an ionic-pair dependent length parameter, and \( r_c \) is the cutoff on both terms.

The styles with coul/cut or coul/long or coul/msm add a Coulombic term as described for the lj/cut pair styles. For buck/coul/long and buck/coul/msm, an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the kspace_style command and its ewald or pppm or msm option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

If one cutoff is specified for the born/coul/cut and born/coul/long and born/coul/msm styles, it is used for both the A,C and Coulombic terms. If two cutoffs are specified, the first is used as the cutoff for the A,C terms, and the second is the cutoff for the Coulombic term.

Note that these potentials are related to the Born-Mayer-Huggins potential.

**Note:** For all these pair styles, the terms with A and C are always cutoff. The additional Coulombic term can be cutoff or long-range (no cutoff) depending on whether the style name includes coul/cut or coul/long or coul/msm. If you wish the C/r^6 term to be long-range (no cutoff), then see the pair_style buck/long/coul/long command.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- A (energy units)
- \( \rho \) (distance units)
- C (energy-distance^6 units)
- cutoff (distance units)
• cutoff2 (distance units)

The second coefficient, \( \rho \), must be greater than zero. The coefficients \( A \), \( \rho \), and \( C \) can be written as analytical expressions of \( \epsilon \) and \( \sigma \), in analogy to the Lennard-Jones potential \((Khrapak)\).

The latter 2 coefficients are optional. If not specified, the global \( A, C \) and Coulombic cutoffs are used. If only one cutoff is specified, it is used as the cutoff for both \( A, C \) and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the \( A, C \) and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style \( buck \), since it has no Coulombic terms. For \( buck/coul/long \) only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

Styles with a \( gpu \), \( intel \), \( kk \), \( omp \), or \( opt \) suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.23.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These styles support the pair_modify shift option for the energy of the \( \exp() \) and \( 1/r^6 \) portion of the pair interaction.

The \( buck/coul/long \) pair style supports the pair_modify table option to tabulate the short-range portion of the long-range Coulombic interaction.

These styles support the pair_modify tail option for adding long-range tail corrections to energy and pressure for the \( A,C \) terms in the pair interaction.

These styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

20.23.5 Restrictions

The \( buck/coul/long \) style is part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

pair_coeff 1 1 1030. 3.061 457.179 4.521 0.608
```
20.25.3 Description

The *buck6d/coul/gauss* styles evaluate vdW and Coulomb interactions following the MOF-FF force field after (Schmid). The vdW term of the *buck6d* styles computes a dispersion damped Buckingham potential:

\[
E = A e^{-r \kappa} - \frac{C}{r^6} \cdot \frac{1}{1 + D r^{14}} \quad r < r_c
\]

where A and C are a force constant, \( \kappa \) is an ionic-pair dependent reciprocal length parameter, D is a dispersion correction parameter, and the cutoff \( r_c \) truncates the interaction distance. The first term in the potential corresponds to the Buckingham repulsion term and the second term to the dispersion attraction with a damping correction analog to the Grimme correction used in DFT. The latter corrects for artifacts occurring at short distances which become an issue for soft vdW potentials.

The *buck6d* styles include a smoothing function which is invoked according to the global smoothing parameter within the specified cutoff. Hereby a parameter of i.e. 0.9 invokes the smoothing within 90% of the cutoff. No smoothing is applied at a value of 1.0. For the *gauss/dsf* style this smoothing is only applicable for the dispersion damped Buckingham potential. For the *gauss/long* styles the smoothing function can also be invoked for the real space coulomb interactions which enforce continuous energies and forces at the cutoff.

Both styles *buck6d/coul/gauss/dsf* and *buck6d/coul/gauss/long* evaluate a Coulomb potential using spherical Gaussian type charge distributions which effectively dampen electrostatic interactions for high charges at close distances. The electrostatic potential is thus evaluated as:

\[
E = \frac{C q_i q_j}{\varepsilon r_{ij}} \text{erf}(\alpha_{ij} r_{ij}) \quad r < r_c
\]

where C is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, epsilon is the dielectric constant which can be set by the *dielectric* command, \( \alpha \) is the ion pair dependent damping parameter and erf() is the error-function. The cutoff \( r_c \) truncates the interaction distance.

The style *buck6d/coul/gauss/dsf* computes the Coulomb interaction via the damped shifted force model described in (Fennell) approximating an Ewald sum similar to the *pair coul/dsf* styles. In *buck6d/coul/gauss/long* an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the *kspace_style* command and its *ewald* or *pppm* options. The Coulombic cutoff in this case separates the real and reciprocal space evaluation of the Ewald sum.

If one cutoff is specified it is used for both the vdW and Coulomb terms. If two cutoffs are specified, the first is used as the cutoff for the vdW terms, and the second is the cutoff for the Coulombic term.

The following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- A (energy units)
- \( \rho \) (distance^-1 units)
- C (energy-distance^6 units)
- D (distance^14 units)
- \( \alpha \) (distance^-1 units)
- cutoff (distance units)

The second coefficient, \( \rho \), must be greater than zero. The latter coefficient is optional. If not specified, the global vdW cutoff is used.
20.25.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly. These styles do not support the pair_modify shift option for the energy. Instead the smoothing function should be applied by setting the global smoothing parameter to a value < 1.0. These styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

20.25.5 Restrictions

These styles are part of the USER-MOFFF package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.26.3 Description

The buck/long/coul/long style computes a Buckingham potential (exp/6 instead of Lennard-Jones 12/6) and Coulombic potential, given by

\[
E = Ae^{-r/\rho} - \frac{C}{r^6}, \quad r < r_c
\]
\[
E = \frac{Cq_iq_j}{\epsilon r^6}, \quad r < r_c
\]

\(r_c\) is the cutoff. If one cutoff is specified in the pair_style command, it is used for both the Buckingham and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the Buckingham and Coulombic terms respectively.

The purpose of this pair style is to capture long-range interactions resulting from both attractive \(1/r^6\) Buckingham and Coulombic \(1/r\) interactions. This is done by use of the flag_buck and flag_coul settings. The Ismail paper has more details on when it is appropriate to include long-range \(1/r^6\) interactions, using this potential.

If flag_buck is set to long, no cutoff is used on the Buckingham \(1/r^6\) dispersion term. The long-range portion can be calculated by using the kspace_style ewald/disp or pppm/disp commands. The specified Buckingham cutoff then determines which portion of the Buckingham interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the Kspace style. If flag_buck is set to cut, the Buckingham interactions are simply cutoff, as with pair_style buck.

If flag_coul is set to long, no cutoff is used on the Coulombic interactions. The long-range portion can be calculated by using any of several kspace_style command options such as pppm or ewald. Note that if flag_buck is also set to long, then the ewald/disp or pppm/disp Kspace style needs to be used to perform the long-range calculations for both the Buckingham and Coulombic interactions. If flag_coul is set to off, Coulombic interactions are not computed.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- A (energy units)
- rho (distance units)
- C (energy-distance^6 units)
- cutoff (distance units)
- cutoff2 (distance units)

The second coefficient, rho, must be greater than zero.

The latter 2 coefficients are optional. If not specified, the global Buckingham and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both Buckingham and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the Buckingham and Coulombic cutoffs for this type pair. Note that if you are using flag_buck set to long, you cannot specify a Buckingham cutoff for an atom type pair, since only one global Buckingham cutoff is allowed. Similarly, if you are using flag_coul set to long, you cannot specify a Coulombic cutoff for an atom type pair, since only one global Coulombic cutoff is allowed.
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.26.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair styles does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

This pair style supports the `pair_modify` shift option for the energy of the exp() and 1/r^6 portion of the pair interaction, assuming `flag_buck` is `cut`.

This pair style does not support the `pair_modify` shift option for the energy of the Buckingham portion of the pair interaction.

This pair style supports the `pair_modify` table and table/disp options since they can tabulate the short-range portion of the long-range Coulombic and dispersion interactions.

This pair style write its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the `inner`, `middle`, and `outer` keywords of the `run_style respa` command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the `run_style` command for details.

### 20.26.5 Restrictions

This style is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.32.3 Description

These pair styles compute Lennard Jones (LJ) and Coulombic interactions with additional switching or shifting functions that ramp the energy and/or force smoothly to zero between an inner and outer cutoff. They are implementations of the widely used CHARMM force field used in the CHARMM MD code (and others). See (MacKerell) for a description of the CHARMM force field.

The styles with charmm (not charmmfsw or charmmfsh) in their name are the older, original LAMMPS implementations. They compute the LJ and Coulombic interactions with an energy switching function (esw, shown in the formula below as $S(r)$), which ramps the energy smoothly to zero between the inner and outer cutoff. This can cause irregularities in pair-wise forces (due to the discontinuous second derivative of energy at the boundaries of the switching region), which in some cases can result in detectable artifacts in an MD simulation.

The newer styles with charmmfsw or charmmfsh in their name replace the energy switching with force switching (fsw) and force shifting (fsh) functions, for LJ and Coulombic interactions respectively. These follow the formulas and description given in (Steinbach) and (Brooks) to minimize these artifacts.
Note: The newer charmmfsw or charmmfsh styles were released in March 2017. We recommend they be used instead of the older charmm styles. This includes the newer dihedral_style charmmfsw command. Eventually code from the new styles will propagate into the related pair styles (e.g. implicit, accelerator, free energy variants).

Note: The newest CHARMM pair styles reset the Coulombic energy conversion factor used internally in the code, from the LAMMPS value to the CHARMM value, as if it were effectively a parameter of the force field. This is because the CHARMM code uses a slightly different value for the this conversion factor in real units (Kcal/mole), namely CHARMM = 332.0716, LAMMPS = 332.06371. This is to enable more precise agreement by LAMMPS with the CHARMM force field energies and forces, when using one of these two CHARMM pair styles.

\[
E = \begin{cases} 
LJ(r) & r < r_{\text{in}} \\
S(r) \times LJ(r) & r_{\text{in}} < r < r_{\text{out}} \\
0 & r > r_{\text{out}} 
\end{cases}
\]

\[
E = \begin{cases} 
C(r) & r < r_{\text{in}} \\
S(r) \times C(r) & r_{\text{in}} < r < r_{\text{out}} \\
0 & r > r_{\text{out}} 
\end{cases}
\]

\[
LJ(r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right]
\]

\[
C(r) = \frac{C_{q_i q_j}}{\epsilon r}
\]

\[
S(r) = \frac{\left[ r_{\text{out}}^2 - r^2 \right]^2 \left[ r_{\text{out}}^2 + 2r^2 - 3r_{\text{in}}^2 \right]}{\left[ r_{\text{out}}^2 - r_{\text{in}}^2 \right]^3}
\]

where \(S(r)\) is the energy switching function mentioned above for the charmm styles. See the \((\text{Steinbach})\) paper for the functional forms of the force switching and force shifting functions used in the charmmfsw and charmmfsh styles.

When using the lj/charmm/coul/charmm styles, both the LJ and Coulombic terms require an inner and outer cutoff. They can be the same for both formulas or different depending on whether 2 or 4 arguments are used in the pair_style command. For the lj/charmmfsw/coul/charmmfsh style, the LJ term requires both an inner and outer cutoff, while the Coulombic term requires only one cutoff. If the Coulombic cutoff is not specified (2 instead of 3 arguments), the LJ outer cutoff is used for the Coulombic cutoff. In all cases where an inner and outer cutoff are specified, the inner cutoff distance must be less than the outer cutoff. It is typical to make the difference between the inner and outer cutoffs about 2.0 Angstroms.

Style lj/charmm/coul/charmm/implicit computes the same formulas as style lj/charmm/coul/charmm except that an additional 1/\(r\) term is included in the Coulombic formula. The Coulombic energy thus varies as 1/\(r^2\). This is effectively a distance-dependent dielectric term which is a simple model for an implicit solvent with additional screening. It is designed for use in a simulation of an unsolvated biomolecule (no explicit water molecules).

Styles lj/charmm/coul/long and lj/charmm/coul/msm compute the same formulas as style lj/charmm/coul/charmm and style lj/charmmfsw/coul/charmmfsh, except that an additional damping factor is applied to the Coulombic term, so it can be used in conjunction with the kspace_style command and its ewald or pppm or msm option. Only one Coulombic cutoff is specified for these styles; if only 2 arguments are used in the pair_style command, then the outer LJ cutoff is used as the single Coulombic cutoff. The Coulombic cutoff specified for these styles means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

20.32. pair_style lj/charmmfsw/coul/long command 1735
• \( \epsilon \) (energy units)
• \( \sigma \) (distance units)
• \( \epsilon_{14} \) (energy units)
• \( \sigma_{14} \) (distance units)

Note that \( \sigma \) is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at \( 2^{1/6} \sigma \).

The latter 2 coefficients are optional. If they are specified, they are used in the LJ formula between 2 atoms of these types which are also first and fourth atoms in any dihedral. No cutoffs are specified because the CHARMM force field does not allow varying cutoffs for individual atom pairs; all pairs use the global cutoff(s) specified in the pair_style command.

Styles with a `gpu`, `intel`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.32.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I and J, the epsilon, sigma, epsilon_14, and sigma_14 coefficients for all of the lj/charmm pair styles can be mixed. The default mix value is arithmetic to coincide with the usual settings for the CHARMM force field. See the “pair_modify” command for details.

None of the `lj/charmm` or `lj/charmmfsw` pair styles support the `pair_modify shift` option, since the Lennard-Jones portion of the pair interaction is smoothed to 0.0 at the cutoff.

The `lj/charmm/coul/long` and `lj/charmmfsw/coul/long` styles support the `pair_modify table` option since they can tabulate the short-range portion of the long-range Coulombic interaction.

None of the `lj/charmm` or `lj/charmmfsw` pair styles support the `pair_modify tail` option for adding long-range tail corrections to energy and pressure, since the Lennard-Jones portion of the pair interaction is smoothed to 0.0 at the cutoff.

All of the `lj/charmm` and `lj/charmmfsw` pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The `lj/charmm/coul/long` and `lj/charmmfsw/coul/long` pair styles support the use of the `inner`, `middle`, and `outer` keywords of the `run_style respa` command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the `pair` keyword of run_style respa. See the `run_style` command for details.
20.32.5 Restrictions

All the styles with *coul/charmm* or *coul/charmmfsh* styles are part of the MOLECULE package. All the styles with *coul/long* style are part of the KSPACE package. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

| pair_coeff | 1 1 100.0 3.5 9.0        |

20.35.3 Description

The lj/class2 styles compute a 6/9 Lennard-Jones potential given by

\[ E = \epsilon \left[ 2 \left( \frac{\sigma}{r} \right)^9 - 3 \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c \]

\( r_c \) is the cutoff.

The lj/class2/coul/cut and lj/class2/coul/long styles add a Coulombic term as described for the lj/cut pair styles.

See (Sun) for a description of the COMPASS class2 force field.

The following coefficients must be defined for each pair of atoms via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global class 2 and Coulombic cutoffs are used. If only one cutoff is specified, it is used as the cutoff for both class 2 and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the class 2 and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style lj/class2, since it has no Coulombic terms.

For lj/class2/coul/long only the class 2 cutoff can be specified since a Coulombic cutoff cannot be specified for an individual IJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

If the pair_coeff command is not used to define coefficients for a particular I \( \neq \) J type pair, the mixing rule for \( \epsilon \) and \( \sigma \) for all class2 potentials is to use the sixthpower formulas documented by the pair_modify command. The pair_modify
mix setting is thus ignored for class2 potentials for epsilon and sigma. However it is still followed for mixing the cutoff distance.

A version of these styles with a soft core, *lj/cut/soft*, suitable for use in free energy calculations, is part of the USER-FEP package and is documented with the *pair_style */soft* styles. The version with soft core is only available if LAMMPS was built with that package. See the *Build package* doc page for more info.

Styles with a *gpu, intel, kk, omp, or opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

### 20.35.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I ≠ J, the epsilon and sigma coefficients and cutoff distance for all of the *lj/class2* pair styles can be mixed. Epsilon and sigma are always mixed with the value *sixthpower*. The cutoff distance is mixed by whatever option is set by the pair_modify command (default = geometric). See the "pair_modify" command for details.

All of the *lj/class2* pair styles support the *pair_modify* shift option for the energy of the Lennard-Jones portion of the pair interaction.

The *lj/class2/coul/long* pair style does not support the *pair_modify* table option since a tabulation capability has not yet been added to this potential.

All of the *lj/class2* pair styles support the *pair_modify* tail option for adding a long-range tail correction to the energy and pressure of the Lennard-Jones portion of the pair interaction.

All of the *lj/class2* pair styles write their information to *binary restart files*, so *pair_style* and *pair_coeff* commands do not need to be specified in an input script that reads a restart file.

Only the *lj/class2* and *lj/class2/coul/long* pair styles support the use of the *inner, middle, and outer* keywords of the *run_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the *pair* keyword of run_style respa. See the *run_style* command for details.

### 20.35.5 Restrictions

These styles are part of the CLASS2 package. They are only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

20.36 \textit{pair_style colloid} command

Accelerator Variants: \textit{colloid/gpu, colloid/omp}

20.36.1 Syntax

\begin{verbatim}
pair_style colloid cutoff

- cutoff = global cutoff for colloidal interactions (distance units)
\end{verbatim}

20.36.2 Examples

\begin{verbatim}
pair_style colloid 10.0
pair_coeff * * 25 1.0 10.0 10.0
pair_coeff 1 1 144 1.0 0.0 0.0 3.0
pair_coeff 1 2 75.398 1.0 0.0 10.0 9.0
pair_coeff 2 2 39.478 1.0 10.0 10.0 25.0
\end{verbatim}

20.36.3 Description

Style \textit{colloid} computes pairwise interactions between large colloidal particles and small solvent particles using 3 formulas. A colloidal particle has a size > sigma; a solvent particle is the usual Lennard-Jones particle of size sigma.
The colloid-colloid interaction energy is given by

\[ U_A = -\frac{A_{cc}}{6} \left[ \frac{2a_1a_2}{r^2 - (a_1 + a_2)^2} + \frac{2a_1a_2}{r^2 - (a_1 - a_2)^2} + \ln \left( \frac{r^2 - (a_1 + a_2)^2}{r^2 - (a_1 - a_2)^2} \right) \right] \]

\[ U_R = \frac{A_{cc}}{37800} \sigma^6 \left[ \frac{r^2}{r} \left( \frac{1}{r - a_1 - a_2} \right)^7 + \frac{r^2}{r} \left( \frac{1}{r + a_1 + a_2} \right)^7 - \frac{r^2}{r} \left( \frac{1}{r + a_1 - a_2} \right)^7 - \frac{r^2}{r} \left( \frac{1}{r - a_1 + a_2} \right)^7 \right] \]

\[ U = U_A + U_R, \quad r < r_c \]

where \( A_{cc} \) is the Hamaker constant, \( a_1 \) and \( a_2 \) are the radii of the two colloidal particles, and \( r_c \) is the cutoff. This equation results from describing each colloidal particle as an integrated collection of Lennard-Jones particles of size \( \sigma \) and is derived in (Everaers).

The colloid-solvent interaction energy is given by

\[ U = \frac{2a^3 \sigma^3 A_{cs}}{9(a^2 - r^2)^3} \left[ 1 - \left( \frac{5a^6 + 45a^4r^2 + 63a^2r^4 + 15r^6}{15(a - r)^6(a + r)^6} \right) \sigma^6 \right], \quad r < r_c \]

where \( A_{cs} \) is the Hamaker constant, \( a \) is the radius of the colloidal particle, and \( r_c \) is the cutoff. This formula is derived from the colloid-colloid interaction, letting one of the particle sizes go to zero.

The solvent-solvent interaction energy is given by the usual Lennard-Jones formula

\[ U = \frac{A_{ss}}{36} \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6}, \quad r < r_c \]

with \( A_{ss} \) set appropriately, which results from letting both particle sizes go to zero.

When used in combination with pair_style Yukawa/colloid, the two terms become the so-called DLVO potential, which combines electrostatic repulsion and van der Waals attraction.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- \( A \) (energy units)
- \( \sigma \) (distance units)
- \( d_1 \) (distance units)
- \( d_2 \) (distance units)
- cutoff (distance units)

\( A \) is the Hamaker energy prefactor and should typically be set as follows:

- \( A_{cc} = \text{colloid/colloid} = 4\pi^2 = 39.5 \)
- \( A_{cs} = \text{colloid/solvent} = \sqrt{A_{cc}A_{ss}} \)
• \( A_{ss} = \text{solvent/solvent} = 144 \) (assuming epsilon = 1, so that 144/36 = 4)

\( \sigma \) is the size of the solvent particle or the constituent particles integrated over in the colloidal particle and should typically be set as follows:

• \( \sigma_{cc} = \text{colloid/colloid} = 1.0 \)
• \( \sigma_{cs} = \text{colloid/solvent} = \text{arithmetic mixing between colloid } \sigma \text{ and solvent } \sigma \)
• \( \sigma_{ss} = \text{solvent/solvent} = 1.0 \) or whatever size the solvent particle is

Thus typically \( \sigma_{cs} = 1.0, \) unless the solvent particle’s size \( \neq 1.0. \)

D1 and d2 are particle diameters, so that d1 = 2*a1 and d2 = 2*a2 in the formulas above. Both d1 and d2 must be values \( \geq 0. \) If d1 > 0 and d2 > 0, then the pair interacts via the colloid-colloid formula above. If d1 = 0 and d2 = 0, then the pair interacts via the solvent-solvent formula. I.e. a d value of 0 is a Lennard-Jones particle of size \( \sigma. \) If either d1 = 0 or d2 = 0 and the other is larger, then the pair interacts via the colloid-solvent formula.

Note that the diameter of a particular particle type may appear in multiple pair_coeff commands, as it interacts with other particle types. You should insure the particle diameter is specified consistently each time it appears.

The last coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used. However, you typically want different cutoffs for interactions between different particle sizes. E.g. if colloidal particles of diameter 10 are used with solvent particles of diameter 1, then a solvent-solvent cutoff of 2.5 would correspond to a colloid-colloid cutoff of 25. A good rule-of-thumb is to use a colloid-solvent cutoff that is half the big diameter + 4 times the small diameter. I.e. \( 9 = 5 + 4 \) for the colloid-solvent cutoff in this case.

Note: When using pair_style colloid for a mixture with 2 (or more) widely different particles sizes (e.g. sigma=10 colloids in a background sigma=1 LJ fluid), you will likely want to use these commands for efficiency: neighbor multi and comm_modify multi.

Styles with a \( \text{gpu, intel, kk, omp, or opt} \) suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.36.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I \(!= J\), the A, sigma, d1, and d2 coefficients and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. D1 and d2 are distance values and are mixed like sigma. The default mix value is \text{geometric}. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.
This pair style writes its information to *binary restart files*, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 20.36.5 Restrictions

This style is part of the COLLOID package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

Normally, this pair style should be used with finite-size particles which have a diameter, e.g. see the *atom_style sphere* command. However, this is not a requirement, since the only definition of particle size is via the pair_coeff parameters for each type. In other words, the physical radius of the particle is ignored. Thus you should insure that the d1,d2 parameters you specify are consistent with the physical size of the particles of that type.

Per-particle polydispersity is not yet supported by this pair style; only per-type polydispersity is enabled via the pair_coeff parameters.

20.38.3 Description

Style *comb* computes the second generation variable charge COMB (Charge-Optimized Many-Body) potential. Style *comb3* computes the third-generation COMB potential. These COMB potentials are described in *(COMB)* and *(COMB3)*. Briefly, the total energy $E_T$ of a system of atoms is given by

$$E_T = \sum_i E_{i}^{self}(q_i) + \sum_{j>i} [E_{ij}^{\text{short}}(r_{ij}, q_i, q_j) + E_{ij}^{\text{Coul}}(r_{ij}, q_i, q_j)] + E_{ij}^{\text{polar}}(q_i, r_{ij}) + E_{ij}^{\text{vdW}}(r_{ij}) + E_{ij}^{\text{barr}}(q_i) + E_{ij}^{\text{corr}}(r_{ij}, \theta_{ijk})$$

where $E_{i}^{\text{self}}$ is the self-energy of atom $i$ (including atomic ionization energies and electron affinities), $E_{ij}^{\text{short}}$ is the bond-order potential between atoms $i$ and $j$, $E_{ij}^{\text{Coul}}$ is the Coulomb interactions, $E_{ij}^{\text{polar}}$ is the polarization term for organic systems (style *comb3* only), $E_{ij}^{\text{vdW}}$ is the van der Waals energy (style *comb3* only), $E_{ij}^{\text{barr}}$ is a charge barrier function, and $E_{ij}^{\text{corr}}$ are angular correction terms.

The COMB potentials (styles *comb* and *comb3*) are variable charge potentials. The equilibrium charge on each atom is calculated by the electronegativity equalization (QEq) method. See Rick for further details. This is implemented by the *fix qeq/comb* command, which should normally be specified in the input script when running a model with the COMB potential. The *fix qeq/comb* command has options that determine how often charge equilibration is performed, its convergence criterion, and which atoms are included in the calculation.

Only a single pair_coeff command is used with the *comb* and *comb3* styles which specifies the COMB potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the potential file in the pair_coeff command, where N is the number of LAMMPS atom types.

For example, if your LAMMPS simulation of a Si/SiO2/HfO2 interface has 4 atom types, and you want the first and last to be Si, the second to be Hf, and the third to be O, and you would use the following pair_coeff command:

<table>
<thead>
<tr>
<th>command</th>
<th>arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>pair_coeff</td>
<td>* * ../potentials/ffield.comb Si Hf O Si</td>
</tr>
</tbody>
</table>

The first two arguments must be * * so as to span all LAMMPS atom types. The first and last Si arguments map LAMMPS atom types 1 and 4 to the Si element in the *ffield.comb* file. The second Hf argument maps LAMMPS atom type 2 to the Hf element, and the third O argument maps LAMMPS atom type 3 to the O element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *comb* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

For style *comb*, the provided potential file *ffield.comb* contains all currently-available second generation COMB parameterizations: for Si, Cu, Hf, Ti, O, their oxides and Zr, Zn and U metals. For style *comb3*, the potential file *ffield.comb3* contains all currently-available third generation COMB parameterizations: O, Cu, N, C, H, Ti, Zn and Zr.

The status of the optimization of the compounds, for example Cu2O, TiN and hydrocarbons, are given in the following table:

- F = Fully optimized
- M = Only optimized for dimer molecule
- P = in progress, but have it from mixing rule

For style `comb3`, in addition to `ffield.comb3`, a special parameter file, `lib.comb3`, that is exclusively used for C/O/H systems, will be automatically loaded if carbon atom is detected in LAMMPS input structure. This file must be in your working directory or in the directories listed in the environment variable `LAMMPS_POTENTIALS`, as described on the `pair_coeff` command doc page.

The keyword `polar` indicates whether the force field includes the atomic polarization. Since the equilibration of the polarization has not yet been implemented, it can only set `polar_off` at present.

**Note:** You cannot use potential file `ffield.comb` with style `comb3`, nor file `ffield.comb3` with style `comb`.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.38.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

These pair styles do not support the `pair_modify` shift, table, and tail options.

These pair styles do not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style`, `pair_coeff`, and `fix qeq/comb` commands in an input script that reads a restart file.

These pair styles can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.
20.38.5 Restrictions

These pair styles are part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair styles requires the newton setting to be “on” for pair interactions.

The COMB potentials in the ffield.comb and ffield.comb3 files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the COMB potential with any LAMMPS units, but you would need to create your own COMB potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

- sigma = distance of the potential minimum from 0
- cutoff = the cutoff distance for this pair type, if different from global (distance units)
- wca = if specified a Weeks-Chandler-Andersen potential (with eps strength and minimum at sigma) is added, otherwise not
20.39.2 Examples

```plaintext
pair_style cosine/squared 3.0
pair_coeff * * 1.0 1.3
pair_coeff 1 3 1.0 1.3 2.0
pair_coeff 1 3 1.0 1.3 wca
pair_coeff 1 3 1.0 1.3 2.0 wca
```

20.39.3 Description

Style `cosine/squared` computes a potential of the form

\[
E = \begin{cases} 
-\epsilon & r < \sigma \\
-\epsilon \cos \left( \frac{\pi (r - \sigma)}{2(r_c - \sigma)} \right)^2 & \sigma \leq r < r_c \\
0 & r \geq r_c 
\end{cases}
\]

between two point particles, where \((\sigma, -\epsilon)\) is the location of the (rightmost) minimum of the potential, as explained in the syntax section above.

This potential was first used in \((\text{Cooke})\) for a coarse-grained lipid membrane model. It is generally very useful as a non-specific interaction potential because it is fully adjustable in depth and width while joining the minimum at \((\sigma, -\epsilon)\) and zero at \((cutoff, 0)\) smoothly, requiring no shifting and causing no related artifacts, tail energy calculations etc. This evidently requires \(cutoff\) to be larger than \(\sigma\).

If the \(wca\) option is used then a Weeks-Chandler-Andersen potential \((\text{Weeks})\) is added to the above specified cosine-squared potential, specifically the following:

\[
E = \epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - 2 \left( \frac{\sigma}{r} \right)^{6} + 1 \right], \quad r < \sigma
\]

In this case, and this case only, the \(\sigma\) parameter can be equal to \(cutoff\) \((\sigma = cutoff)\) which will result in ONLY the WCA potential being used (and print a warning), so the minimum will be attained at \((\sigma, 0)\). This is a convenience feature that enables a purely repulsive potential to be used without a need to define an additional pair style and use the hybrid styles.

The energy and force of this pair style for parameters \(\epsilon = 1.0\), \(\sigma = 1.0\), \(cutoff = 2.5\), with and without the WCA potential, are shown in the graphs below:
20.39.4 Mixing, shift, table, tail correction, restart, rRESPA info

Mixing is not supported for this style.
The shift, table and tail options are not relevant for this style.
This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.
These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

20.39.5 Restrictions

The cosine/squared style is part of the USER-MISC package. It is only enabled if LAMMPS is build with that package. See the Build package doc page for more info.

20.48.3 Description

The `coul/cut` style computes the standard Coulombic interaction potential given by

\[ E = \frac{Cq_i q_j}{\epsilon r} \quad r < r_c \]

where C is an energy-conversion constant, Q_i and Q_j are the charges on the 2 atoms, and \( \epsilon \) is the dielectric constant which can be set by the `dielectric` command. The cutoff \( r_c \) truncates the interaction distance.

Style `coul/debye` adds an additional exp() damping factor to the Coulombic term, given by

\[ E = \frac{Cq_i q_j}{\epsilon r} \exp(-\kappa r) \quad r < r_c \]

where \( \kappa \) is the Debye length. This potential is another way to mimic the screening effect of a polar solvent.

Style `coul/dsf` computes Coulombic interactions via the damped shifted force model described in Fennell, given by:

\[ E = q_i q_j \left[ \frac{\text{erfc}(\alpha r)}{r} - \frac{\text{erfc}(\alpha r_c)}{r_c} + \left( \frac{\text{erfc}(\alpha r_c)}{r_c^2} + \frac{2\alpha \exp(-\alpha^2 r_c^2)}{\sqrt{\pi}} \frac{1}{r_c} \right) (r - r_c) \right] \quad r < r_c \]
where $\alpha$ is the damping parameter and erfc() is the complementary error-function. The potential corrects issues in the Wolf model (described below) to provide consistent forces and energies (the Wolf potential is not differentiable at the cutoff) and smooth decay to zero.

Style `coul/wolf` computes Coulombic interactions via the Wolf summation method, described in Wolf, given by:

$$E_i = \frac{1}{2} \sum_{j \neq i} q_i q_j \frac{erfc(\alpha r_{ij})}{r_{ij}} + \frac{1}{2} \sum_{j \neq i} q_i q_j \frac{erf(\alpha r_{ij})}{r_{ij}} \quad r < r_c$$

where $\alpha$ is the damping parameter, and erf() and erfc() are error-function and complementary error-function terms. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise $1/r$ summation. With a manipulation of adding and subtracting a self term (for $i = j$) to the first and second term on the right-hand-side, respectively, and a small enough $\alpha$ damping parameter, the second term shrinks and the potential becomes a rapidly-converging real-space summation. With a long enough cutoff and small enough $\alpha$ parameter, the energy and forces calculated by the Wolf summation method approach those of the Ewald sum. So it is a means of getting effective long-range interactions with a short-range potential.

Style `coul/streitz` is the Coulomb pair interaction defined as part of the Streitz-Mintmire potential, as described in this paper, in which charge distribution about an atom is modeled as a Slater 1s orbital. More details can be found in the referenced paper. To fully reproduce the published Streitz-Mintmire potential, which is a variable charge potential, style `coul/streitz` must be used with `pair_style eam/alloy` (or some other short-range potential that has been parameterized appropriately) via the `pair_style hybrid/overlay` command. Likewise, charge equilibration must be performed via the `fix qeq/slater` command. For example:

```
pair_style hybrid/overlay coul/streitz 12.0 wolf 0.31 eam/alloy
pair_coeff * * coul/streitz AlO.streitz Al O
pair_coeff * * eam/alloy AlO.eam.alloy Al O
fix 1 all qeq/slater 1 12.0 1.0e-6 100 coul/streitz
```

The keyword `wolf` in the `coul/streitz` command denotes computing Coulombic interactions via Wolf summation. An additional damping parameter is required for the Wolf summation, as described for the `coul/wolf` potential above. Alternatively, Coulombic interactions can be computed via an Ewald summation. For example:

```
pair_style hybrid/overlay coul/streitz 12.0 ewald eam/alloy
kspace_style ewald 1e-6
```

Keyword `ewald` does not need a damping parameter, but a `kspace_style` must be defined, which can be style `ewald` or `pppm`. The Ewald method was used in Streitz and Mintmire’s original paper, but a Wolf summation offers a speed-up in some cases.

For the fix `qeq/slater` command, the `qfile` can be a filename that contains QEq parameters as discussed on the `fix qeq` command doc page. Alternatively, `qfile` can be replaced by “coul/streitz”, in which case the fix will extract QEq parameters from the coul/streitz pair style itself.

See the examples/streitz directory for an example input script that uses the Streitz-Mintmire potential. The potentials directory has the AlO.eam.alloy and AlO.streitz potential files used by the example.

Note that the Streitz-Mintmire potential is generally used for oxides, but there is no conceptual problem with extending it to nitrides and carbides (such as SiC, TiN). Pair coul/streitz used by itself or with any other pair style such as EAM, MEAM, Tersoff, or LJ in hybrid/overlay mode. To do this, you would need to provide a Streitz-Mintmire parameterization for the material being modeled.

Styles `coul/long` and `coul/msm` compute the same Coulombic interactions as style `coul/cut` except that an additional damping factor is applied so it can be used in conjunction with the `kspace_style` command and its `ewald` or `pppm`
option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

Styles \textit{tip4p/cut} and \textit{tip4p/long} implement the Coulomb part of the TIP4P water model of \textit{(Jorgensen)}, which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as pair_style arguments. Style \textit{tip4p/cut} uses a global cutoff for Coulomb interactions; style \textit{tip4p/long} is for use with a long-range Coulombic solver (Ewald or PPPM).

\textbf{Note:} For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

See the \textit{Howto tip4p} doc page for more information on how to use the TIP4P pair styles and lists of parameters to set. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance 2*qdist when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff >= Coulombic cutoff + 2*qdist, to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

Note that these potentials are designed to be combined with other pair potentials via the \textit{pair_style hybrid/overlay} command. This is because they have no repulsive core. Hence if they are used by themselves, there will be no repulsion to keep two oppositely charged particles from moving arbitrarily close to each other.

The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the data or restart files read by the \textit{read_data} or \textit{read restart} commands, or by mixing as described below:

- \texttt{cutoff} (distance units)

For \texttt{coul/cut} and \texttt{coul/debye}, the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the pair_style command is used.

For \texttt{coul/long} and \texttt{coul/msm} no cutoff can be specified for an individual IJ type pair via the \texttt{pair_coeff} command. All type pairs use the same global Coulomb cutoff specified in the pair_style command.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix command-line switch} when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.
20.48.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I ≠ J, the cutoff distance for the coul/cut style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

The pair_modify shift option is not relevant for these pair styles.

The coul/long style supports the pair_modify table option for tabulation of the short-range portion of the long-range Coulombic interaction.

These pair styles do not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

20.48.5 Restrictions

The coul/long, coul/msm and tip4p/long styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.49 pair_style coul/diel command

Accelerator Variants: coul/diel/omp
20.49.1 Syntax

pair_style coul/diel cutoff

cutoff = global cutoff (distance units)

20.49.2 Examples

pair_style coul/diel 3.5
pair_coeff 1 4 78. 1.375 0.112

20.49.3 Description

Style coul/diel computes a Coulomb correction for implicit solvent ion interactions in which the dielectric permittivity is distance dependent. The dielectric permittivity $\epsilon_D(r)$ connects to limiting regimes: One limit is defined by a small dielectric permittivity (close to vacuum) at or close to contact separation between the ions. At larger separations the dielectric permittivity reaches a bulk value used in the regular Coulomb interaction coul/long or coul/cut. The transition is modeled by a hyperbolic function which is incorporated in the Coulomb correction term for small ion separations as follows

$$E = \frac{Cq_i q_j}{\epsilon r} \left( \frac{\epsilon}{\epsilon_D(r)} - 1 \right) \quad r < r_c$$

$$\epsilon_D(r) = \frac{5.2 + \epsilon}{2} + \frac{\epsilon - 5.2}{2} \tanh \left( \frac{r - r_{me}}{\sigma_e} \right)$$

where $r_{me}$ is the inflection point of $\epsilon_D(r)$ and $\sigma_e$ is a slope defining length scale. $C$ is the same Coulomb conversion factor as in the pair_styles coul/cut, coul/long, and coul/debye. In this way the Coulomb interaction between ions is corrected at small distances $r$. The lower limit of $\epsilon_D(r=0)=5.2$ due to dielectric saturation (Stiles) while the Coulomb interaction reaches its bulk limit by setting $\epsilon_D(r \to \infty) = \epsilon$, the bulk value of the solvent which is 78 for water at 298K.

Examples of the use of this type of Coulomb interaction include implicit solvent simulations of salt ions (Lenart) and of ionic surfactants (Jusufi). Note that this potential is only reasonable for implicit solvent simulations and in combination with coul/cut or coul/long. It is also usually combined with gauss/cut, see (Lenart) or (Jusufi).

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- $\epsilon$ (no units)
- $r_{me}$ (distance units)
- $\sigma_e$ (distance units)

The global cutoff ($r_c$) specified in the pair_style command is used.
20.49.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support parameter mixing. Coefficients must be given explicitly for each type of particle pairs.

This pair style supports the pair_modify shift option for the energy of the Gauss-potential portion of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.49.5 Restrictions

This style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

\]

\[
\text{Tap}(r_{ij}) = 20 \left( \frac{r_{ij}}{R_{cut}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{cut}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{cut}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{cut}} \right)^4 + 1
\]

Where \( \text{Tap}(r_{ij}) \) is the taper function which provides a continuous cutoff (up to third derivative) for inter-atomic separations larger than \( r_c \) (Leven1), (Leven2) and (Maaravi). Here \( \lambda \) is the shielding parameter that eliminates the short-range singularity of the classical mono-polar electrostatic interaction expression (Maaravi).

The shielding parameter \( \lambda \) (1/distance units) must be defined for each pair of atom types via the `pair_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands.

The global cutoff \( r_c \) specified in the `pair_style` command is used.

20.50.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support parameter mixing. Coefficients must be given explicitly for each type of particle pairs.

The `pair_modify table` option is not relevant for this pair style.

This pair style does not support the `pair_modify tail` option for adding long-range tail corrections to energy and pressure.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.
20.50.5 Restrictions

This style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

```
20.53.3 Description

Styles `coul/slater` compute electrostatic interactions in mesoscopic models which employ potentials without explicit excluded-volume interactions. The goal is to prevent artificial ionic pair formation by including a charge distribution in the Coulomb potential, following the formulation of (Melchor):

$$E = \frac{Cq_i q_j}{cr} \left( 1 - \left( 1 + \frac{r_{ij}}{\lambda} \exp \left( -\frac{2r_{ij}}{\lambda} \right) \right) \right) \quad r < r_c$$

where \(r_c\) is the cutoff distance and \(\lambda\) is the decay length of the charge. \(C\) is the same Coulomb conversion factor as in the pair_styles `coul/cut` and `coul/long`. In this way the Coulomb interaction between ions is corrected at small distances \(r\). For the `coul/slater/cut` style, the potential energy for distances larger than the cutoff is zero, while for the `coul/slater/long`, the long-range interactions are computed either by the Ewald or the PPPM technique.

Phenomena that can be captured at a mesoscopic level using this type of electrostatic interactions include the formation of polyelectrolyte-surfactant aggregates, charge stabilization of colloidal suspensions, and the formation of complexes driven by charged species in biological systems. (Vaiwala).

The cutoff distance is optional. If it is not used, the default global value specified in the pair_style command is used. For each pair of atom types, a specific cutoff distance can be defined via the `pair_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \(r_c\) (distance units)

The global decay length of the charge (\(\lambda\)) specified in the pair_style command is used for all pairs.

20.53.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \(!=\) J, the cutoff distance for the `coul/slater` styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

The `pair_modify` shift and table options are not relevant for these pair styles.

These pair styles do not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

20.53.5 Restrictions

The `coul/slater/long` style requires the long-range solvers included in the KSPACE package.

These styles are part of the USER-MISC package. They are only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

These pair styles are designed to be used with the adiabatic core/shell model of (Mitchell and Finchham). See the Howto coreshell doc page for an overview of the model as implemented in LAMMPS.

All the styles are identical to the corresponding pair style without the “/cs” in the name:

- pair_style born/coul/dsf
- pair_style born/coul/long
- pair_style born/coul/wolf
- pair_style buck/coul/long
- pair_style coul/long
- pair_style coul/wolf
- pair_style lj/cut/coul/long
- pair_style lj/class2/coul/long

except that they correctly treat the special case where the distance between two charged core and shell atoms in the same core/shell pair approach $r = 0.0$.

Styles with a “/long” in the name are used with a long-range solver for Coulombic interactions via the kspace_style command. They require special treatment of the short-range Coulombic interactions within the cor/shell model.

Specifically, the short-range Coulomb interaction between a core and its shell should be turned off using the special_bonds command by setting the 1-2 weight to 0.0, which works because the core and shell atoms are bonded to each other. This induces a long-range correction approximation which fails at small distances ($\sim 10^{-8}$). Therefore, the Coulomb term which is used to calculate the correction factor is extended by a minimal distance ($r_{\text{min}} = 1.0-6$) when the interaction between a core/shell pair is treated, as follows:

$$E = \frac{C q_i q_j}{\epsilon (r + r_{\text{min}})} \quad r \to 0$$

where $C$ is an energy-conversion constant, $q_i$ and $q_j$ are the charges on the core and shell, epsilon is the dielectric constant and $r_{\text{min}}$ is the minimal distance.

For styles that are not used with a long-range solver, i.e. those with “/dsf” or “/wolf” in the name, the only correction is the addition of a minimal distance to avoid the possible $r = 0.0$ case for a core/shell pair.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.
See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.61.4 Mixing, shift, table, tail correction, restart, rRESPA info

See the corresponding doc pages for pair styles without the “cs” suffix to see how mixing, shifting, tabulation, tail correction, restarting, and rRESPA are handled by these pair styles.

20.61.5 Restrictions

These pair styles are part of the CORESHELL package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.65.3 Description

Style \emph{lj/cut/dipole/cut} computes interactions between pairs of particles that each have a charge and/or a point dipole moment. In addition to the usual Lennard-Jones interaction between the particles (Elj) the charge-charge (Eqq), charge-dipole (Eqp), and dipole-dipole (Epp) interactions are computed by these formulas for the energy (E), force
(F), and torque (T) between particles I and J.

\[
E_{\text{LJ}} = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right]
\]

\[
E_{\text{qq}} = \frac{q_i q_j}{r}
\]

\[
E_{\text{qp}} = \frac{q_i}{r^3} (p_i \cdot \vec{r})
\]

\[
E_{\text{pp}} = \frac{1}{r^4} (\vec{p}_i \cdot \vec{p}_j) - \frac{3}{r^5} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \cdot \vec{r})
\]

\[
F_{\text{qq}} = \frac{q_i q_j}{r^2} \vec{r}
\]

\[
F_{\text{qp}} = -\frac{q_i}{r^3} \vec{p} + \frac{3 q_i}{r^5} (\vec{p} \cdot \vec{r}) \vec{r}
\]

\[
F_{\text{pp}} = \frac{3}{r^6} (\vec{p}_i \cdot \vec{p}_j) \vec{r} - \frac{15}{r^7} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \cdot \vec{r}) \vec{r} + \frac{3}{r^5} [(\vec{p}_j \cdot \vec{r}) \vec{p}_i + (\vec{p}_i \cdot \vec{r}) \vec{p}_j]
\]

\[
T_{\text{pq}} = T_{\text{ij}} = \frac{q_i}{r^3} (\vec{p}_i \times \vec{r})
\]

\[
T_{\text{qp}} = T_{\text{ji}} = -\frac{q_i}{r^3} (\vec{p}_j \times \vec{r})
\]

\[
T_{\text{pp}} = T_{\text{ij}} = -\frac{1}{r^3} (\vec{p}_i \times \vec{p}_j) + \frac{3}{r^5} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \times \vec{r})
\]

\[
T_{\text{pp}} = T_{\text{ji}} = -\frac{1}{r^3} (\vec{p}_j \times \vec{p}_i) + \frac{3}{r^5} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \times \vec{r})
\]

where \( q_i \) and \( q_j \) are the charges on the two particles, \( \vec{p}_i \) and \( \vec{p}_j \) are the dipole moment vectors of the two particles, \( r \) is their separation distance, and the vector \( r = R_i - R_j \) is the separation vector between the two particles. Note that \( E_{\text{qq}} \) and \( F_{\text{qq}} \) are simply Coulombic energy and force, \( F_{\text{ij}} = -F_{\text{ji}} \) as symmetric forces, and \( T_{\text{ij}} \neq -T_{\text{ji}} \) since the torques do not act symmetrically. These formulas are discussed in Allen and in Toukmaji.

Also note, that in the code, all of these terms (except \( E_{\text{LJ}} \)) have a \( C/\epsilon \) prefactor, the same as the Coulombic term in the \( \text{LJ} + \text{Coulombic} \) pair styles discussed here. \( C \) is an energy-conversion constant and epsilon is the dielectric constant which can be set by the dielectric command. The same is true of the equations that follow for other dipole pair styles.

Style \text{lj/sf/dipole/sf} \ computes “shifted-force” interactions between pairs of particles that each have a charge and/or a point dipole moment. In general, a shifted-force potential is a (slightly) modified potential containing extra terms that make both the energy and its derivative go to zero at the cutoff distance; this removes (cutoff-related) problems in energy conservation and any numerical instability in the equations of motion (Allen). Shifted-force interactions for the Lennard-Jones (\( E_{\text{LJ}} \)), charge-charge (\( E_{\text{qq}} \)), charge-dipole (\( E_{\text{qp}} \)), dipole-charge (\( E_{\text{pq}} \)) and dipole-dipole (\( E_{\text{pp}} \))
potentials are computed by these formulas for the energy (E), force (F), and torque (T) between particles I and J:

\[
E_{LJ} = 4\epsilon \left\{ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right\} + \left[ 6 \left( \frac{\sigma}{r_c} \right)^{12} - 3 \left( \frac{\sigma}{r_c} \right)^{6} \right] \left( \frac{r}{r_c} \right)^{2} - 7 \left( \frac{\sigma}{r_c} \right)^{12} + 4 \left( \frac{\sigma}{r_c} \right)^{6} \right\}
\]

\[
E_{qq} = \frac{q_i q_j}{r} \left( 1 - \frac{r}{r_c} \right)^2
\]

\[
E_{pq} = E_{ji} = -\frac{q_i}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] (\vec{p} \cdot \vec{r})
\]

\[
E_{qp} = E_{ij} = \frac{q_j}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] (\vec{p} \cdot \vec{r})
\]

\[
E_{pp} = \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] \left[ \frac{1}{r^2} (\vec{p}_i \cdot \vec{p}_j) - \frac{3}{r^2} (\vec{p}_i \cdot \vec{r}) (\vec{p}_j \cdot \vec{r}) \right]
\]

\[
F_{LJ} = \left\{ 48\epsilon \left( \frac{\sigma}{r} \right)^{12} - 24\epsilon \left( \frac{\sigma}{r} \right)^{6} \right\} \frac{1}{r^2} - \left[ 48\epsilon \left( \frac{\sigma}{r_c} \right)^{12} - 24\epsilon \left( \frac{\sigma}{r_c} \right)^{6} \right] \frac{1}{r^2} \right\} \vec{r}
\]

\[
F_{qq} = \frac{q_i q_j}{r} \left( \frac{1}{r^2} - \frac{1}{r_c^2} \right) \vec{r}
\]

\[
F_{pq} = F_{ij} = -\frac{3q_i}{r^3} \left[ 1 - \left( \frac{r}{r_c} \right)^2 \right] (\vec{p} \cdot \vec{r}) \vec{r} + \frac{q_j}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] \vec{p}
\]

\[
F_{qp} = F_{ij} = \frac{3q_j}{r^3} \left[ 1 - \left( \frac{r}{r_c} \right)^2 \right] (\vec{p} \cdot \vec{r}) \vec{r} - \frac{q_i}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] \vec{p}
\]

\[
F_{pp} = \frac{3}{r^5} \left\{ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right\} \left[ (\vec{p}_i \cdot \vec{p}_j) \vec{p}_i + (\vec{p}_i \cdot \vec{r}) (\vec{p}_j \cdot \vec{r}) - \frac{2}{r^2} (\vec{p}_i \cdot \vec{r}) (\vec{p}_j \cdot \vec{r}) \vec{r} \right]
\]

\[
T_{pq} = T_{ij} = \frac{q_j}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] (\vec{p}_i \times \vec{r})
\]

\[
T_{qp} = T_{ji} = -\frac{q_i}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] (\vec{p}_j \times \vec{r})
\]

\[
T_{pp} = T_{ij} = -\frac{1}{r^3} \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] (\vec{p}_i \times \vec{p}_j) + \frac{3}{r^5} \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] (\vec{p}_i \cdot \vec{r}) (\vec{p}_j \times \vec{r})
\]

\[
T_{pp} = T_{ji} = -\frac{1}{r^3} \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] (\vec{p}_j \times \vec{p}_i) + \frac{3}{r^5} \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] (\vec{p}_i \cdot \vec{r}) (\vec{p}_j \times \vec{r})
\]

where \( \epsilon \) and \( \sigma \) are the standard LJ parameters, \( r_c \) is the cutoff, \( q_i \) and \( q_j \) are the charges on the two particles, \( \vec{p}_i \) and \( \vec{p}_j \) are the dipole moment vectors of the two particles, \( r \) is their separation distance, and the vector \( r = \vec{R}_i - \vec{R}_j \) is the
separation vector between the two particles. Note that $E_{qq}$ and $F_{qq}$ are simply Coulombic energy and force, $F_{ij} = -F_{ji}$ as symmetric forces, and $T_{ij} = -T_{ji}$ since the torques do not act symmetrically. The shifted-force formula for the Lennard-Jones potential is reported in (Stoddard). The original (non-shifted) formulas for the electrostatic potentials, forces and torques can be found in (Price). The shifted-force electrostatic potentials have been obtained by applying equation 5.13 of (Allen). The formulas for the corresponding forces and torques have been obtained by applying the ‘chain rule’ as in appendix C.3 of (Allen).

If one cutoff is specified in the pair_style command, it is used for both the LJ and Coulombic $(q,p)$ terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic $(q,p)$ terms respectively. This pair style also supports an optional scale keyword as part of a pair_coeff statement, where the interactions can be scaled according to this factor. This scale factor is also made available for use with fix adapt.

Style lj/cut/dipole/long computes long-range point-dipole interactions as discussed in (Toukmaji). Dipole-dipole, dipole-charge, and charge-charge interactions are all supported, along with the standard 12/6 Lennard-Jones interactions, which are computed with a cutoff. A kspace_style must be defined to use this pair style. Currently, only kspace_style ewald/disp support long-range point-dipole interactions.

Style lj/long/dipole/long also computes point-dipole interactions as discussed in (Toukmaji). Long-range dipole-dipole, dipole-charge, and charge-charge interactions are all supported, along with the standard 12/6 Lennard-Jones interactions. LJ interactions can be cutoff or long-ranged.

For style lj/long/dipole/long, if flag_lj is set to long, no cutoff is used on the LJ $1/r^6$ dispersion term. The long-range portion is calculated by using the kspace_style ewald_disp command. The specified LJ cutoff then determines which portion of the LJ interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the Kspace style. If flag_lj is set to cut, the LJ interactions are simply cutoff, as with pair_style lj/cut. If flag_lj is set to off, LJ interactions are not computed at all.

If flag_coul is set to long, no cutoff is used on the Coulombic or dipole interactions. The long-range portion is calculated by using ewald_disp of the kspace_style command. If flag_coul is set to off, Coulombic and dipole interactions are not computed at all.

Atoms with dipole moments should be integrated using the fix nve/sphere update dipole or the fix nvt/sphere update dipole command to rotate the dipole moments. The omega option on the fix langevin command can be used to thermostat the rotational motion. The compute temp/sphere command can be used to monitor the temperature, since it includes rotational degrees of freedom. The atom_style hybrid dipole sphere command should be used since it defines the point dipoles and their rotational state. The magnitude and orientation of the dipole moment for each particle can be defined by the set command or in the “Atoms” section of the data file read in by the read_data command.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

---

### 20.65.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

For atom type pairs I,J and I != J, the A, sigma, d1, and d2 coefficients and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. D1 and d2 are distance values and are mixed like sigma. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction; such energy goes to zero at the cutoff by construction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

---

### 20.65.5 Restrictions

The lj/cut/dipole/cut, lj/cut/dipole/long, and lj/long/dipole/long styles are part of the DIPOLE package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The lj/sf/dipole/sf style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Using dipole pair styles with electron units is not currently supported.

---

pair_coeff  *  * 1.0
pair_coeff  1  1 1.0 1.0
```
20.67.3 Description

Style *dpd* computes a force field for dissipative particle dynamics (DPD) following the exposition in *Groot*.

Style *dpd/tstat* invokes a DPD thermostat on pairwise interactions, which is equivalent to the non-conservative portion of the DPD force field. This pair-wise thermostat can be used in conjunction with any *pair style*, and in lieu of per-particle thermostats like *fix langevin* or ensemble thermostats like Nose Hoover as implemented by *fix nvt*. To use *dpd/tstat* as a thermostat for another pair style, use the *pair_style hybrid/overlay* command to compute both the desired pair interaction and the thermostat for each pair of particles.

For style *dpd*, the force on atom I due to atom J is given as a sum of 3 terms

\[
\vec{f} = (F^C + F^D + F^R) \hat{r}_{ij} \quad r < r_c
\]

\[
F^C = A w(r)
\]

\[
F^D = -\gamma w^2(r) (\vec{r}_{ij} \cdot \vec{v}_{ij})
\]

\[
F^R = \sigma w(r) \alpha (\Delta t)^{-1/2}
\]

\[
w(r) = 1 - r/r_c
\]

where \( F^C \) is a conservative force, \( F^D \) is a dissipative force, and \( F^R \) is a random force. \( \vec{r}_{ij} \) is a unit vector in the direction \( r_i - r_j \), \( \vec{v}_{ij} \) is the vector difference in velocities of the two atoms \( = \vec{v}_i - \vec{v}_j \), \( \alpha \) is a Gaussian random number with zero mean and unit variance, \( \Delta t \) is the timestep size, and \( w(r) \) is a weighting factor that varies between 0 and 1. \( r_c \) is the cutoff. \( \sigma \) is set equal to \( \sqrt{2 \kappa B T \gamma} \), where \( \kappa B \) is the Boltzmann constant and \( T \) is the temperature parameter in the *pair_style* command.

For style *dpd/tstat*, the force on atom I due to atom J is the same as the above equation, except that the conservative \( F^C \) term is dropped. Also, during the run, \( T \) is set each timestep to a ramped value from \( T_{start} \) to \( T_{stop} \).

For style *dpd*, the pairwise energy associated with style *dpd* is only due to the conservative force term \( F^C \), and is shifted to be zero at the cutoff distance \( R_c \). The pairwise virial is calculated using all 3 terms. For style *dpd/tstat* there is no pairwise energy, but the last two terms of the formula make a contribution to the virial.

For style *dpd*, the following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- A (force units)
- \( \gamma \) (force/velocity units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used. Note that \( \sigma \) is set equal to \( \sqrt{2 \kappa B T \gamma} \), where \( \kappa B \) is the Boltzmann constant and \( T \) is the temperature set by the *pair_style* command so it does not need to be specified.

For style *dpd/tstat*, the coefficients defined for each pair of atoms types via the *pair_coeff* command is the same, except that A is not included.

The GPU-accelerated versions of these styles are implemented based on the work of *Afshar* and *Phillips*.

**Note:** If you are modeling DPD polymer chains, you may want to use the *pair_style srp* command in conjunction with these pair styles. It is a soft segmental repulsive potential (SRP) that can prevent DPD polymer chains from crossing each other.

**Note:** The virial calculation for pressure when using these pair styles includes all the components of force listed above, including the random force. Since the random force depends on random numbers, everything that changes the order of atoms in the neighbor list (e.g. different number of MPI ranks or a different neighbor list skin distance) will
also change the sequence in which the random numbers are applied and thus the individual forces and therefore also
the virial/pressure.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix.
They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages*
doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off
and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively.
They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix*
command-line switch when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

### 20.67.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These pair styles do not support the *pair_modify* shift option for the energy of the pair interaction. Note that as
discussed above, the energy due to the conservative Fc term is already shifted to be 0.0 at the cutoff distance Rc.

The *pair_modify* table option is not relevant for these pair styles.

These pair styles do not support the *pair_modify* tail option for adding long-range tail corrections to energy and pressure.

These pair styles writes their information to binary restart files, so pair_style and pair_coeff commands do not need to
be specified in an input script that reads a restart file. Note that the user-specified random number seed is stored in the
restart file, so when a simulation is restarted, each processor will re-initialize its random number generator the same
way it did initially. This means the random forces will be random, but will not be the same as they would have been if
the original simulation had continued past the restart time.

These pair styles can only be used via the *pair* keyword of the *run_style respa* command. They do not support the
*inner*, *middle*, *outer* keywords.

The *dpd/tstat* style can ramp its target temperature over multiple runs, using the *start* and *stop* keywords of the *run*
command. See the *run* command for details of how to do this.

### 20.67.5 Restrictions

The default frequency for rebuilding neighbor lists is every 10 steps (see the *neigh_modify* command). This may be
too infrequent for style *dpd* simulations since particles move rapidly and can overlap by large amounts. If this setting
yields a non-zero number of “dangerous” reneighboring (printed at the end of a simulation), you should experiment
with forcing reneighboring more often and see if system energies/trajectories change.

These pair styles requires you to use the *comm_modify vel yes* command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the *read_restart* command, though they should provide statistically
similar results. This is because the forces they compute depend on atom velocities. See the *read_restart* command for
more details.
20.67.6 Related commands

pair_coeff, fix nvt, fix langevin, pair_style srp

20.67.7 Default

none

20.68 pair_style dpd/fdt command

20.69 pair_style dpd/fdt/energy command

Accelerator Variants: dpd/fdt/energy/kk

20.69.1 Syntax

```
pair_style style args
```

- style = dpd/fdt or dpd/fdt/energy
- args = list of arguments for a particular style

dpd/fdt args = T cutoff seed
  T = temperature (temperature units)
  cutoff = global cutoff for DPD interactions (distance units)
  seed = random # seed (positive integer)

dpd/fdt/energy args = cutoff seed
  cutoff = global cutoff for DPD interactions (distance units)
  seed = random # seed (positive integer)

20.69.2 Examples

```
pair_style dpd/fdt 300.0 2.5 34387
pair_coeff  * * 3.0 1.0 2.5

pair_style dpd/fdt/energy 2.5 34387
pair_coeff  * * 3.0 1.0 0.1 2.5
```
20.69.3 Description

Styles dpd/fdt and dpd/fdt/energy compute the force for dissipative particle dynamics (DPD) simulations. The dpd/fdt style is used to perform DPD simulations under isothermal and isobaric conditions, while the dpd/fdt/energy style is used to perform DPD simulations under isoenergetic and isoenthalpic conditions (see (Lisal)). For DPD simulations in general, the force on atom I due to atom J is given as a sum of 3 terms

\[ \vec{f} = (F^C + F^D + F^R) \hat{r}_{ij} \quad r < r_c \]

\[ F^C = Aw(r) \]
\[ F^D = -\gamma w^2(r)(\vec{r}_{ij} \cdot \vec{v}_{ij}) \]
\[ F^R = \sigma w(r) \alpha(\Delta t)^{-1/2} \]
\[ w(r) = 1 - \frac{r_{ij}}{r_c} \]

where \( F^C \) is a conservative force, \( F^D \) is a dissipative force, and \( F^R \) is a random force. \( r_{ij} \) is a unit vector in the direction \( \vec{r}_i - \vec{r}_j \), \( \vec{v}_{ij} \) is the vector difference in velocities of the two atoms:

\[ \alpha_{ij}^2 = 2k_B \kappa_{ij} \]
\[ \sigma_{ij}^2 = 2\gamma_{ij} k_B \Theta_{ij} \]
\[ \Theta_{ij}^{-1} = \frac{1}{2} \left( \frac{1}{\theta_i} + \frac{1}{\theta_j} \right) \]

\( \zeta_{ij} \) is a second Gaussian random number with zero mean and unit variance that is used to compute the internal conductive energy. The fluctuation-dissipation theorem defines \( \alpha^2 \) to be set equal to \( \sigma^2/2\theta \), where \( \Theta \) is the average internal temperature for the pair. The particle internal temperature is related to the particle internal energy through a mesoparticle equation of state (see fix eos). The differential internal conductive and mechanical energies are computed within style dpd/fdt/energy as:

\[ du_{\text{cond}}^t = \kappa_{ij} \left( \frac{1}{\theta_i} - \frac{1}{\theta_j} \right) \omega_{ij}^2 + \alpha_{ij} \omega_{ij} \zeta_{ij} (\Delta t)^{-1/2} \]
\[ du_{\text{mech}}^t = -\frac{1}{2} \gamma_{ij} \omega_{ij} \left( \frac{1}{\theta_i} \omega_{ij} + \frac{1}{\theta_j} \right)^2 - \frac{\sigma_{ij}^2}{4} \left( \frac{1}{m_i} + \frac{1}{m_j} \right) \omega_{ij}^2 - \frac{1}{2} \sigma_{ij} \omega_{ij} \zeta_{ij} (\Delta t)^{-1/2} \]

Note that alternative definitions of the weighting function exist, but would have to be implemented as a separate pair style command.

For style dpd/fdt, the fluctuation-dissipation theorem defines \( \gamma \) to be set equal to \( \sigma^2/(2T) \), where \( T \) is the set point temperature specified as a pair style parameter in the above examples. The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- \( A \) (force units)
- \( \sigma \) (force*time^(1/2) units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used.

Style dpd/fdt/energy is used to perform DPD simulations under isoenergetic and isoenthalpic conditions. The fluctuation-dissipation theorem defines \( \gamma \) to be set equal to \( \sigma^2/(2\theta) \), where \( \Theta \) is the average internal temperature for the pair. The particle internal temperature is related to the particle internal energy through a mesoparticle equation of state (see fix eos). The differential internal conductive and mechanical energies are computed within style dpd/fdt/energy as:

\[ du_{\text{cond}}^t = \kappa_{ij} \left( \frac{1}{\theta_i} - \frac{1}{\theta_j} \right) \omega_{ij}^2 + \alpha_{ij} \omega_{ij} \zeta_{ij} (\Delta t)^{-1/2} \]
\[ du_{\text{mech}}^t = -\frac{1}{2} \gamma_{ij} \omega_{ij} \left( \frac{1}{\theta_i} \omega_{ij} + \frac{1}{\theta_j} \right)^2 - \frac{\sigma_{ij}^2}{4} \left( \frac{1}{m_i} + \frac{1}{m_j} \right) \omega_{ij}^2 - \frac{1}{2} \sigma_{ij} \omega_{ij} \zeta_{ij} (\Delta t)^{-1/2} \]
is the mesoparticle thermal conductivity parameter. The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- A (force units)
- $\sigma$ (force*time^(1/2) units)
- $\kappa$ (energy*temperature/time units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used.

The pairwise energy associated with styles `dpd/fdt` and `dpd/fdt/energy` is only due to the conservative force term $F_c$, and is shifted to be zero at the cutoff distance $R_c$. The pairwise virial is calculated using only the conservative term.

The forces computed through the `dpd/fdt` and `dpd/fdt/energy` styles can be integrated with the velocity-Verlet integration scheme or the Shardlow splitting integration scheme described by (Lisal). In the cases when these pair styles are combined with the `fix shardlow`, these pair styles differ from the other dpd styles in that the dissipative and random forces are split from the force calculation and are not computed within the pair style. Thus, only the conservative force is computed by the pair style, while the stochastic integration of the dissipative and random forces are handled through the Shardlow splitting algorithm approach. The Shardlow splitting algorithm is advantageous, especially when performing DPD under isoenergetic conditions, as it allows significantly larger timesteps to be taken.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

### 20.69.4 Restrictions

These commands are part of the USER-DPD package. They are only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

Pair styles `dpd/fdt` and `dpd/fdt/energy` require use of the `comm_modify vel yes` option so that velocities are stored by ghost atoms.

Pair style `dpd/fdt/energy` requires `atom_style dpd` to be used in order to properly account for the particle internal energies and temperatures.
20.69.5 Related commands

pair_coeff, fix shrdlow

20.69.6 Default

none

20.70 pair_style drip command

20.70.1 Syntax

\texttt{pair\_style hybrid/overlay drip [styles ...]}

- styles = other styles to be overlayed with drip (optional)

20.70.2 Examples

\begin{verbatim}
pair_style hybrid/overlay drip
pair_coeff * * none
pair_coeff * * drip C.drip C

pair_style hybrid/overlay drip rebo
pair_coeff * * drip C.drip C
pair_coeff * * rebo CH.airebo C

pair_style hybrid/overlay drip rebo
pair_coeff * * drip C.drip C NULL
pair_coeff * * rebo CH.airebo C H
\end{verbatim}

20.70.3 Description

Style \textit{drip} computes the interlayer interactions of layered materials using the dihedral-angle-corrected registry-dependent (DRIP) potential as described in (Wen), which is based on the (Kolmogorov) potential and provides an improved prediction for forces. The total potential energy of a system is

\[ E = \frac{1}{2} \sum_i \sum_{j \in \text{layer} i} \phi_{ij} \]

\[ \phi_{ij} = f_c(x_r) \left[ e^{-\lambda(r_{ij} - z_0)} \left[ C + f(\rho_{ij}) + g(\rho_{ij}, \{a_{ij}^{(m)}\}) \right] - A \left( \frac{z_0}{r_{ij}} \right)^6 \right] \]

where the $r^{-6}$ term models the attractive London dispersion, the exponential term is designed to capture the registry effect due to overlapping $pi$ bonds, and $f_c$ is a cutoff function.
This potential (DRIP) only provides the interlayer interactions between graphene layers. So, to perform a realistic simulation, it should be used in combination with an intralayer potential such as REBO and Tersoff. To keep the intralayer interactions unaffected, we should avoid applying DRIP to contribute energy to intralayer interactions. This can be achieved by assigning different molecular IDs to atoms in different layers, and DRIP is implemented such that only atoms with different molecular ID can interact with each other. For this purpose, *atom style* “molecular” or “full” has to be used.

On the other way around, REBO (Tersoff or any other potential used to provide the intralayer interactions) should not interfere with the interlayer interactions described by DRIP. This is typically automatically achieved using the commands provided in the Examples section above, since the cutoff distance for carbon-carbon interaction in the intralayer potentials (e.g., 2 Angstrom for REBO) is much smaller than the equilibrium layer distance of graphene layers (about 3.4 Angstrom). If you want, you can enforce this by assigning different atom types to atoms in different layers, and apply an intralayer potential to one atom type. See *pair_hybrid* for details.

The *pair_coeff* command for DRIP takes $4+N$ arguments, where $N$ is the number of LAMMPS atom types. The first three arguments must be fixed to be * * drip, the fourth argument is the path to the DRIP parameter file, and the remaining $N$ arguments specifying the mapping between element in the parameter file and atom types. For example, if your LAMMPS simulation has 3 atom types and you want all of them to be C, you would use the following *pair_coeff* command:

```
pair_coeff  * * drip  C.drip  C C C
```

If a mapping value is specified as NULL, the mapping is not performed. This could be useful when DRIP is used to model part of the system where other element exists. Suppose you have a hydrocarbon system, with C of atom type 1 and H of atom type 2, you can use the following command to inform DRIP not to model H atoms:

```
pair_style  hybrid/overlay drip rebo
pair_coeff  * * drip  C.drip  C NULL
pair_coeff  * * rebo  CH.airebo  C H
```

**Note:** The potential parameters developed in (Wen) are provided with LAMMPS (see the “potentials” directory). Besides those in Wen, an additional parameter “normal_cutoff”, specific to the LAMMPS implementation, is used to find the three nearest neighbors of an atom to construct the normal.

---

### 20.70.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair_modify mix*, *shift*, *table*, and *tail* options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the *pair_style* and *pair_coeff* commands in an input script that reads a restart file.
20.70.5 Restrictions

This pair style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair potential requires the newton setting to be “on” for pair interactions.

The C.drip parameter file provided with LAMMPS (see the “potentials” directory) is parameterized for metal units. You can use the DRIP potential with any LAMMPS units, but you would need to create your own custom parameter file with coefficients listed in the appropriate units, if your simulation does not use “metal” units.

20.70.6 Related commands

pair_style lebedeva_z, pair_style kolmogorov/crespi/z, pair_style kolmogorov/crespi/full, pair_style ilp/graphene/hbn.

20.71 pair_style dsmc command

20.71.1 Syntax

```
pair_style dsmc max_cell_size seed weighting Tref Nrecompute Nsample
```

- max_cell_size = global maximum cell size for DSMC interactions (distance units)
- seed = random # seed (positive integer)
- weighting = macroparticle weighting
- Tref = reference temperature (temperature units)
- Nrecompute = re-compute v*sigma_max every this many timesteps (timesteps)
- Nsample = sample this many times in recomputing v*sigma_max

20.71.2 Examples

```
pair_style dsmc 2.5 34387 10 1.0 100 20
pair_coeff * * 1.0
pair_coeff 1 1 1.0
```
20.71.3 Description

Style `dsmc` computes collisions between pairs of particles for a direct simulation Monte Carlo (DSMC) model following the exposition in *(Bird)*. Each collision resets the velocities of the two particles involved. The number of pairwise collisions for each pair or particle types and the length scale within which they occur are determined by the parameters of the `pair_style` and `pair_coeff` commands.

Stochastic collisions are performed using the variable hard sphere (VHS) approach, with the user-defined `max_cell_size` value used as the maximum DSMC cell size, and reference cross-sections for collisions given using the `pair_coeff` command.

There is no pairwise energy or virial contributions associated with this pair style.

The following coefficient must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- sigma (area units, i.e. distance-squared)

The global DSMC `max_cell_size` determines the maximum cell length used in the DSMC calculation. A structured mesh is overlayed on the simulation box such that an integer number of cells are created in each direction for each processor’s sub-domain. Cell lengths are adjusted up to the user-specified maximum cell size.

To perform a DSMC simulation with LAMMPS, several additional options should be set in your input script, though LAMMPS does not check for these settings.

Since this pair style does not compute particle forces, you should use the “fix nve/noforce” time integration fix for the DSMC particles, e.g.

```
fix 1 all nve/noforce
```

This pair style assumes that all particles will communicated to neighboring processors every timestep as they move. This makes it possible to perform all collisions between pairs of particles that are on the same processor. To ensure this occurs, you should use these commands:

```
neighbor 0.0 bin
neigh_modify every 1 delay 0 check no
atom_modify sort 0 0.0
communicate single cutoff 0.0
```

These commands ensure that LAMMPS communicates particles to neighboring processors every timestep and that no ghost atoms are created. The output statistics for a simulation run should indicate there are no ghost particles or neighbors.

In order to get correct DSMC collision statistics, users should specify a Gaussian velocity distribution when populating the simulation domain. Note that the default velocity distribution is uniform, which will not give good DSMC collision rates. Specify “dist gaussian” when using the `velocity` command as in the following:

```
velocity all create 594.6 87287 loop geom dist gaussian
```
20.71.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This pair style does not support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. Note that the user-specified random number seed is stored in the restart file, so when a simulation is restarted, each processor will re-initialize its random number generator the same way it did initially. This means the random forces will be random, but will not be the same as they would have been if the original simulation had continued past the restart time.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.71.5 Restrictions

This style is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.72.3 Description

The e3b style computes an "explicit three-body" (E3B) potential for water (Kumar 2008).

\[ E = E_2 \sum_{i,j} e^{-k_2 r_{ij}} + E_A \sum_{i,j,k,\ell \in \text{type A}} f(r_{ij})f(r_{k\ell}) + E_B \sum_{i,j,k,\ell \in \text{type B}} f(r_{ij})f(r_{k\ell}) + E_C \sum_{i,j,k,\ell \in \text{type C}} f(r_{ij})f(r_{k\ell}) \]

\[ f(r) = e^{-k_3 r} s(r) \]

\[ s(r) = \begin{cases} 
1 & r < R_s \\
\frac{(R_f - r)^2(R_f - 3R_s + 2r)}{(R_f - R_s)^3} & R_s \leq r \leq R_f \\
0 & r > R_f 
\end{cases} \]

This potential was developed as a water model that includes the three-body cooperativity of hydrogen bonding explicitly. To use it in this way, it must be applied in conjunction with a conventional two-body water model, through pair_style hybrid/overlay. The three body interactions are split into three types: A, B, and C. Type A corresponds to anti-cooperative double hydrogen bond donor interactions. Type B corresponds to the cooperative interaction of molecules that both donate and accept a hydrogen bond. Type C corresponds to anti-cooperative double hydrogen bond acceptor interactions. The three-body interactions are smoothly cutoff by the switching function \( s(r) \) between Rs and Rc3. The two-body interactions are designed to correct for the effective many-body interactions implicitly included in the conventional two-body potential. The two-body interactions are cut off sharply at Rc2, because K3 is typically significantly smaller than K2. See (Kumar 2008) for more details.
Only a single `pair_coeff` command is used with the `e3b` style. The first two arguments must be `* *`. The oxygen atom type for the pair style is passed as the only argument to the `pair_style` command, not in the `pair_coeff` command. The hydrogen atom type is inferred by the ordering of the atoms.

**Note:** Every atom of type `Otype` must be part of a water molecule. Each water molecule must have consecutive IDs with the oxygen first. This pair style does not test that this criteria is met.

The `pair_coeff` command must have at least one keyword/value pair, as described above. The `preset` keyword sets the potential parameters to the values used in (Tainter 2011) or (Tainter 2015). To use the water models defined in those references, the `e3b` style should always be used in conjunction with an `lj/cut/.tip4p/long` style through `pair_style hybrid/overlay`, as demonstrated in the second example above. The `preset 2011` option should be used with the `TIP4P water model`. The `preset 2015` option should be used with the `TIP4P/2005 water model`. If the `preset` keyword is used, no other keyword is needed. Changes to the preset parameters can be made by specifying the `preset` keyword followed by the specific parameter to change, like `Ea`. Note that the other keywords must come after `preset` in the `pair_style` command. The `e3b` style can also be used to implement any three-body potential of the same form by specifying all the keywords except `neigh`: `Ea`, `Eb`, `Ec`, `E2`, `K3`, `K2`, `Rc3`, `Rc2`, `Rs`, and `bondL`. The keyword `bondL` specifies the intramolecular OH bond length of the water model being used. This is needed to include H atoms that are within the cutoff even when the attached oxygen atom is not.

This pair style allocates arrays sized according to the number of pairwise interactions within `Rc3`. To do this it needs an estimate for the number of water molecules within `Rc3` of an oxygen atom. This estimate defaults to 10 and can be changed using the `neigh` keyword, which takes an integer as an argument. If the neigh setting is too small, the simulation will fail with the error “neigh is too small”. If the neigh setting is too large, the pair style will use more memory than necessary.

This pair style tallies a breakdown of the total E3B potential energy into sub-categories, which can be accessed via the `compute pair` command as a vector of values of length 4. The 4 values correspond to the terms in the first equation above: the `E2` term, the `Ea` term, the `Eb` term, and the `Ec` term.

See the examples/USER/misc/e3b directory for a complete example script.

### 20.72.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to `binary restart files`. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style is incompatible with `respa`.

### 20.72.5 Restrictions

This pair style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

This pair style requires a fixed number of atoms in the simulation, so it is incompatible with fixes like `fix deposit`. If the number of atoms changes between runs, this pair style must be re-initialized by calling the `pair_style` and `pair_coeff`s commands. This is not a fundamental limitation of the pair style, but the code currently does not support a variable number of atoms.

The `preset` keyword currently only works with real, metal, si, and cgs `units`.

20.77.3 Description

Style *eam* computes pairwise interactions for metals and metal alloys using embedded-atom method (EAM) potentials (*Daw*). The total energy \( E_i \) of an atom \( I \) is given by

\[
E_i = F_\alpha \left( \sum_{j \neq i} \rho_\beta(r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha\beta}(r_{ij})
\]

where \( F \) is the embedding energy which is a function of the atomic electron density \( \rho \), \( \phi \) is a pair potential interaction, and \( \alpha \) and \( \beta \) are the element types of atoms \( I \) and \( J \). The multi-body nature of the EAM potential is a result of the embedding energy term. Both summations in the formula are over all neighbors \( J \) of atom \( I \) within the cutoff distance.

The cutoff distance and the tabulated values of the functionals \( F \), \( \rho \), and \( \phi \) are listed in one or more files which are specified by the *pair_coeff* command. These are ASCII text files in a DYNAMO-style format which is described below. DYNAMO was the original serial EAM MD code, written by the EAM originators. Several DYNAMO potential files for different metals are included in the “potentials” directory of the LAMMPS distribution. All of these files are parameterized in terms of LAMMPS metal units.

**Note:** The *eam* style reads single-element EAM potentials in the DYNAMO *funcfl* format. Either single element or alloy systems can be modeled using multiple *funcfl* files and style *eam*. For the alloy case LAMMPS mixes the single-element potentials to produce alloy potentials, the same way that DYNAMO does. Alternatively, a single DYNAMO *seffl* file or Finnis/Sinclair EAM file can be used by LAMMPS to model alloy systems by invoking the *eam/alloy* or *eam/cd* or *eam/fs* styles as described below. These files require no mixing since they specify alloy interactions explicitly.

**Note:** Note that unlike for other potentials, cutoffs for EAM potentials are not set in the *pair_style* or *pair_coeff* command; they are specified in the EAM potential files themselves. Likewise, the EAM potential files list atomic masses; thus you do not need to use the *mass* command to specify them.

There are several WWW sites that distribute and document EAM potentials stored in DYNAMO or other formats:

- [http://www.ctcms.nist.gov/potentials](http://www.ctcms.nist.gov/potentials)
- [https://openkim.org](https://openkim.org)
These potentials should be usable with LAMMPS, though the alternate formats would need to be converted to the DYNAMO format used by LAMMPS and described on this page. The NIST site is maintained by Chandler Becker (cbecker at nist.gov) who is good resource for info on interatomic potentials and file formats.

The OpenKIM Project at https://openkim.org/browse/models/by-type provides EAM potentials that can be used directly in LAMMPS with the kim_commands interface.

For style eam, potential values are read from a file that is in the DYNAMO single-element funcfl format. If the DYNAMO file was created by a Fortran program, it cannot have “D” values in it for exponents. C only recognizes “e” or “E” for scientific notation.

Note that unlike for other potentials, cutoffs for EAM potentials are not set in the pair_style or pair_coeff command; they are specified in the EAM potential files themselves.

For style eam a potential file must be assigned to each I,I pair of atom types by using one or more pair_coeff commands, each with a single argument:

• filename

Thus the following command

```
pair_coeff *2 1*2 cuu3.eam
```

will read the cuu3 potential file and use the tabulated Cu values for F, phi, rho that it contains for type pairs 1,1 and 2,2 (type pairs 1,2 and 2,1 are ignored). See the pair_coeff doc page for alternate ways to specify the path for the potential file. In effect, this makes atom types 1 and 2 in LAMMPS be Cu atoms. Different single-element files can be assigned to different atom types to model an alloy system. The mixing to create alloy potentials for type pairs with I != J is done automatically the same way that the serial DYNAMO code originally did it; you do not need to specify coefficients for these type pairs.

Funcfl files in the potentials directory of the LAMMPS distribution have an “.eam” suffix. A DYNAMO single-element funcfl file is formatted as follows:

• line 1: comment (ignored)

• line 2: atomic number, mass, lattice constant, lattice type (e.g. FCC)

• line 3: Nrho, drho, Nr, dr, cutoff

On line 2, all values but the mass are ignored by LAMMPS. The mass is in mass units, e.g. mass number or grams/mole for metal units. The cubic lattice constant is in Angstroms. On line 3, Nrho and drho are the number of tabulated values in the subsequent arrays, drho and dr are the spacing in density and distance space for the values in those arrays, and the specified cutoff becomes the pairwise cutoff used by LAMMPS for the potential. The units of dr are Angstroms; I’m not sure of the units for drho - some measure of electron density.

Following the three header lines are three arrays of tabulated values:

• embedding function F(rho) (Nrho values)

• effective charge function Z(r) (Nr values)

• density function rho(r) (Nr values)

The values for each array can be listed as multiple values per line, so long as each array starts on a new line. For example, the individual Z(r) values are for r = 0,dr,2*dr,…,(Nr-1)*dr.

The units for the embedding function F are eV. The units for the density function rho are the same as for drho (see above, electron density). The units for the effective charge Z are “atomic charge” or sqrt(Hartree * Bohr-radii). For two interacting atoms i,j this is used by LAMMPS to compute the pair potential term in the EAM energy expression as r*phi, in units of eV-Angstroms, via the formula

\[ r \cdot \phi = 27.2 \cdot 0.529 \cdot Z_i \cdot Z_j \]
LAMMPS Documentation

where 1 Hartree = 27.2 eV and 1 Bohr = 0.529 Angstroms.

Style *eam/alloy* computes pairwise interactions using the same formula as style *eam*. However the associated *pair_coeff* command reads a DYNAMO *setfl* file instead of a *funcfl* file. *Setfl* files can be used to model a single-element or alloy system. In the alloy case, as explained above, *setfl* files contain explicit tabulated values for alloy interactions. Thus they allow more generality than *funcfl* files for modeling alloys.

For style *eam/alloy*, potential values are read from a file that is in the DYNAMO multi-element *setfl* format, except that element names (Ni, Cu, etc) are added to one of the lines in the file. If the DYNAMO file was created by a Fortran program, it cannot have “D” values in it for exponents. C only recognizes “e” or “E” for scientific notation.

Only a single *pair_coeff* command is used with the *eam/alloy* style which specifies a DYNAMO *setfl* file, which contains information for M elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the *pair_coeff* command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of *setfl* elements to atom types

As an example, the potentials/NiAlH_jea.eam.alloy file is a *setfl* file which has tabulated EAM values for 3 elements and their alloy interactions: Ni, Al, and H. See the *pair_coeff* doc page for alternate ways to specify the path for the potential file. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Ni, and the fourth to be Al, you would use the following *pair_coeff* command:

```
pair_coeff * * NiAlH_jea.eam.alloy Ni Ni Ni Al
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three Ni arguments map LAMMPS atom types 1,2,3 to the Ni element in the *setfl* file. The final Al argument maps LAMMPS atom type 4 to the Al element in the *setfl* file. Note that there is no requirement that your simulation use all the elements specified by the *setfl* file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an *eam/alloy* potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

*Setfl* files in the *potentials* directory of the LAMMPS distribution have an “.eam.alloy” suffix. A DYNAMO multi-element *setfl* file is formatted as follows:

- lines 1,2,3 = comments (ignored)
- line 4: Nelements Element1 Element2 ... ElementN
- line 5: Nrho, drho, Nr, dr, cutoff

In a DYNAMO *setfl* file, line 4 only lists Nelements = the # of elements in the *setfl* file. For LAMMPS, the element name (Ni, Cu, etc) of each element must be added to the line, in the order the elements appear in the file.

The meaning and units of the values in line 5 is the same as for the *funcfl* file described above. Note that the cutoff (in Angstroms) is a global value, valid for all pairwise interactions for all element pairings.

Following the 5 header lines are Nelements sections, one for each element, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function F(rho) (Nrho values)
- density function rho(r) (Nr values)

As with the *funcfl* files, only the mass (in mass units, e.g. mass number or grams/mole for metal units) is used by LAMMPS from the first line. The cubic lattice constant is in Angstroms. The F and rho arrays are unique to a single element and have the same format and units as in a *funcfl* file.
Following the Nelements sections, Nr values for each pair potential phi(r) array are listed for all i,j element pairs in the same format as other arrays. Since these interactions are symmetric (i,j = j,i) only phi arrays with i >= j are listed, in the following order: i,j = (1,1), (2,1), (2,2), (3,1), (3,2), (3,3), (4,1), . . . , (Nelements, Nelements). Unlike the effective charge array Z(r) in funcfl files, the tabulated values for each phi function are listed in setfl files directly as r*phi (in units of eV-Angstroms), since they are for atom pairs.

Style eam/cd is similar to the eam/alloy style, except that it computes alloy pairwise interactions using the concentration-dependent embedded-atom method (CD-EAM). This model can reproduce the enthalpy of mixing of alloys over the full composition range, as described in (Stukowski). Style eam/cd/old is an older, slightly different and slower two-site formulation of the model (Caro).

The pair_coeff command is specified the same as for the eam/alloy style. However the DYNAMO setfl file must have two lines added to it, at the end of the file:

- line 1: Comment line (ignored)
- line 2: N Coefficient0 Coefficient1 . . . CoefficientN

The last line begins with the degree N of the polynomial function h(x) that modifies the cross interaction between A and B elements. Then N+1 coefficients for the terms of the polynomial are then listed.

Modified EAM setfl files used with the eam/cd style must contain exactly two elements, i.e. in the current implementation the eam/cd style only supports binary alloys. The first and second elements in the input EAM file are always taken as the A and B species.

CD-EAM files in the potentials directory of the LAMMPS distribution have a “.cdeam” suffix.

Style eam/fs computes pairwise interactions for metals and metal alloys using a generalized form of EAM potentials due to Finnis and Sinclair (Finnis). The total energy Ei of an atom I is given by

$$E_i = F_\alpha \left( \sum_{j \neq i} \rho_{\alpha\beta}(r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha\beta}(r_{ij})$$

This has the same form as the EAM formula above, except that rho is now a functional specific to the atomic types of both atoms I and J, so that different elements can contribute differently to the total electron density at an atomic site depending on the identity of the element at that atomic site.

The associated pair_coeff command for style eam/fs reads a DYNAMO setfl file that has been extended to include additional rho_alpha_beta arrays of tabulated values. A discussion of how FS EAM differs from conventional EAM alloy potentials is given in (Ackland1). An example of such a potential is the same author’s Fe-P FS potential (Ackland2). Note that while FS potentials always specify the embedding energy with a square root dependence on the total density, the implementation in LAMMPS does not require that; the user can tabulate any functional form desired in the FS potential files.

For style eam/fs, the form of the pair_coeff command is exactly the same as for style eam/alloy, e.g.

```
pair_coeff * * NiAlH_jea.eam.fs Ni Ni Ni Al
```

where there are N additional arguments after the filename, where N is the number of LAMMPS atom types. See the pair_coeff doc page for alternate ways to specify the path for the potential file. The N values determine the mapping of LAMMPS atom types to EAM elements in the file, as described above for style eam/alloy. As with eam/alloy, if a mapping value is NULL, the mapping is not performed. This can be used when an eam/fs potential is used as part of the hybrid pair style. The NULL values are used as placeholders for atom types that will be used with other potentials.

FS EAM files include more information than the DYNAMO setfl format files read by eam/alloy, in that i,j density functionals for all pairs of elements are included as needed by the Finnis/Sinclair formulation of the EAM.
FS EAM files in the *potentials* directory of the LAMMPS distribution have an “.eam.fs” suffix. They are formatted as follows:

- lines 1,2,3 = comments (ignored)
- line 4: Nelements Element1 Element2 . . . ElementN
- line 5: Nrho, drho, Nr, dr, cutoff

The 5-line header section is identical to an EAM *setfl* file.

Following the header are Nelements sections, one for each element I, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function F(rho) (Nrho values)
- density function rho(r) for element I at element 1 (Nr values)
- density function rho(r) for element I at element 2
- ...
- density function rho(r) for element I at element Nelements

The units of these quantities in line 1 are the same as for *setfl* files. Note that the rho(r) arrays in Finnis/Sinclair can be asymmetric (i,j != j,i) so there are Nelements^2 of them listed in the file.

Following the Nelements sections, Nr values for each pair potential phi(r) array are listed in the same manner (r*phi, units of eV-Angstroms) as in EAM *setfl* files. Note that in Finnis/Sinclair, the phi(r) arrays are still symmetric, so only phi arrays for i >= j are listed.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

### 20.77.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above with the individual styles. You never need to specify a pair_coeff command with I != J arguments for the eam styles.

This pair style does not support the pair_modify shift, table, and tail options.

The eam pair styles do not write their information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

The eam pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.
20.77.5 Restrictions

All of these styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.78 pair_style edip command

Accelerator Variants: edip/omp

20.79 pair_style edip/multi command

20.79.1 Syntax

```
pair_style style
```

- style = edip or edip/multi

20.79.2 Examples

```
pair_style edip
pair_coeff * * Si.edip Si
```
20.79.3 Description

The *edip* and *edip/multi* styles compute a 3-body EDIP potential which is popular for modeling silicon materials where it can have advantages over other models such as the Stillinger-Weber or Tersoff potentials. The *edip* style has been programmed for single element potentials, while *edip/multi* supports multi-element EDIP runs.

In EDIP, the energy $E$ of a system of atoms is

$$ E = \sum_{j \neq i} \phi_2(R_{ij}, Z_i) + \sum_{j \neq i} \sum_{k \neq i, k > j} \phi_3(R_{ij}, R_{ik}, Z_i) $$

\[ \phi_2(r, Z) = A \left[ \left( \frac{B}{r} \right)^\alpha - e^{-\beta Z^2} \right] \exp \left( \frac{\sigma}{r - a} \right) \]

\[ \phi_3(R_{ij}, R_{ik}, Z_i) = \exp \left( \frac{\gamma}{R_{ij} - a} \right) \exp \left( \frac{\gamma}{R_{ik} - a} \right) h(\cos \theta_{ijk}, Z_i) \]

\[ Z_i = \sum_{m \neq i} f(R_{im}) \quad f(r) = \begin{cases} 1 & r < c \\ \exp \left( \frac{-\alpha}{1-x} \right) & c < r < a \\ 0 & r > a \end{cases} \]

\[ h(l, Z) = \lambda \left[ (1 - e^{-Q(Z)(l+\tau(Z))^2}) + \eta Q(Z)(l+\tau(Z))^2 \right] \]

\[ Q(Z) = Q_0 e^{-\mu Z} \quad \tau(Z) = u_1 + u_2 (u_3 e^{-u_4 Z} - e^{-2u_4 Z}) \]

where $\phi_2$ is a two-body term and $\phi_3$ is a three-body term. The summations in the formula are over all neighbors $J$ and $K$ of atom $I$ within a cutoff distance $= a$. Both terms depend on the local environment of atom $I$ through its effective coordination number defined by $Z$, which is unity for a cutoff distance $< c$ and gently goes to 0 at distance $> a$.

Only a single pair_coeff command is used with the *edip* style which specifies a EDIP potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying $N$ additional arguments after the filename in the pair_coeff command, where $N$ is the number of LAMMPS atom types:

- filename
- $N$ element names = mapping of EDIP elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, imagine a file Si.edip has EDIP values for Si.

EDIP files in the potentials directory of the LAMMPS distribution have a “.edip” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- A (energy units)
- B (distance units)
- cutoffA (distance units)
- cutoffC (distance units)
- $\alpha$
- $\beta$
- $\eta$
- $\gamma$ (distance units)
• lambda (energy units)
• \( \mu \)
• \( \tau \)
• \( \sigma \) (distance units)
• Q0
• u1
• u2
• u3
• u4

The A, B, beta, sigma parameters are used only for two-body interactions. The eta, gamma, lambda, mu, Q0 and all u1 to u4 parameters are used only for three-body interactions. The alpha and cutoffC parameters are used for the coordination environment function only.

The EDIP potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify EDIP parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

At the moment, only a single element parameterization is implemented. However, the author is not aware of other multi-element EDIP parameterization. If you know any and you are interest in that, please contact the author of the EDIP package.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.79.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.
20.79.5 Restrictions

This pair style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The EDIP potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the EDIP potential with any LAMMPS units, but you would need to create your own EDIP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

```
This pair style contains a LAMMPS implementation of the electron Force Field (eFF) potential currently under development at Caltech, as described in (Jaramillo-Botero). The eFF for Z<6 was first introduced by (Su) in 2007. It has been extended to higher Zs by using effective core potentials (ECPs) that now cover up to second and third row p-block elements of the periodic table.

eFF can be viewed as an approximation to QM wave packet dynamics and Fermionic molecular dynamics, combining the ability of electronic structure methods to describe atomic structure, bonding, and chemistry in materials, and of plasma methods to describe nonequilibrium dynamics of large systems with a large number of highly excited electrons. Yet, eFF relies on a simplification of the electronic wave function in which electrons are described as floating Gaussian wave packets whose position and size respond to the various dynamic forces between interacting classical nuclear particles and spherical Gaussian electron wave packets. The wave function is taken to be a Hartree product of the wave packets. To compensate for the lack of explicit antisymmetry in the resulting wave function, a spin-dependent Pauli potential is included in the Hamiltonian. Substituting this wave function into the time-dependent Schrödinger equation produces equations of motion that correspond - to second order - to classical Hamiltonian relations between electron position and size, and their conjugate momenta. The N-electron wave function is described as a product of one-electron Gaussian functions, whose size is a dynamical variable and whose position is not constrained to a nuclear center. This form allows for straightforward propagation of the wave function, with time, using a simple formulation from which the equations of motion are then integrated with conventional MD algorithms. In addition to this spin-dependent Pauli repulsion potential term between Gaussians, eFF includes the electron kinetic energy from the Gaussians. These two terms are based on first-principles quantum mechanics. On the other hand, nuclei are described as point charges, which interact with other nuclei and electrons through standard electrostatic potential forms.

The full Hamiltonian (shown below), contains then a standard description for electrostatic interactions between a set of delocalized point and Gaussian charges which include, nuclei-nuclei (NN), electron-electron (ee), and nuclei-electron (Ne). Thus, eFF is a mixed QM-classical mechanics method rather than a conventional force field method (in which electron motions are averaged out into ground state nuclear motions, i.e a single electronic state, and particle interactions are described via empirically parameterized interatomic potential functions). This makes eFF uniquely suited to simulate materials over a wide range of temperatures and pressures where electronically excited and ionized states of matter can occur and coexist. Furthermore, the interactions between particles -nuclei and electrons- reduce to the sum of a set of effective pairwise potentials in the eFF formulation. The eff/cut style computes the pairwise Coulomb interactions between nuclei and electrons (E_{NN},E_{Ne},E_{ee}), and the quantum-derived Pauli (E_{PR}) and Kinetic energy interactions potentials between electrons (E_{KE}) for a total energy expression given as,

\[ U(R,r,s) = E_{NN}(R) + E_{Ne}(R,r,s) + E_{ee}(r,s) + E_{KE}(r,s) + E_{PR}(\uparrow \downarrow, S) \]

The individual terms are defined as follows:

\[ E_{KE} = \frac{\hbar^2}{2m_i} \sum_i 3 \frac{s_i^2}{2} \]

\[ E_{NN} = \frac{1}{4\pi\varepsilon_0} \sum_{i<j} Z_i Z_j \frac{1}{R_{ij}} \]

\[ E_{Ne} = -\frac{1}{4\pi\varepsilon_0} \sum_{i,j} \frac{Z_i}{R_{ij}} \text{Erf} \left( \frac{\sqrt{2}R_{ij}}{s_j} \right) \]

\[ E_{ee} = \frac{1}{4\pi\varepsilon_0} \sum_{i<j} \frac{1}{r_{ij}} \text{Erf} \left( \frac{\sqrt{2}r_{ij}}{s_i + s_j} \right) \]

\[ E_{Pauli} = \sum_{\sigma_i = \sigma_j} E(\uparrow \uparrow)_{ij} + \sum_{\sigma_i \neq \sigma_j} E(\uparrow \downarrow)_{ij} \]

where, s_i correspond to the electron sizes, the sigmas i’s to the fixed spins of the electrons, Z_i to the charges on the
nuclei, \( R_{ij} \) to the distances between the nuclei or the nuclei and electrons, and \( r_{ij} \) to the distances between electrons.

For additional details see (Jaramillo-Botero).

The overall electrostatics energy is given in Hartree units of energy by default and can be modified by an energy-conversion constant, according to the units chosen (see \texttt{electron_units}). The cutoff \( R_c \), given in Bohrs (by default), truncates the interaction distance. The recommended cutoff for this pair style should follow the minimum image criterion, i.e. half of the minimum unit cell length.

Style \texttt{eff/long} (not yet available) computes the same interactions as style \texttt{eff/cut} except that an additional damping factor is applied so it can be used in conjunction with the \texttt{kspace_style} command and its \texttt{ewald} or \texttt{pppm} option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

This potential is designed to be used with \texttt{atom_style electron} definitions, in order to handle the description of systems with interacting nuclei and explicit electrons.

The following coefficients must be defined for each pair of atoms types via the \texttt{pair_coeff} command as in the examples above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands, or by mixing as described below:

- cutoff (distance units)

For \texttt{eff/cut}, the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the \texttt{pair_style} command is used.

For \texttt{eff/long} (not yet available) no cutoff will be specified for an individual I,J type pair via the \texttt{pair_coeff} command. All type pairs use the same global cutoff specified in the \texttt{pair_style} command.

The \texttt{limit/eradius} and \texttt{pressure/evirials} keywords are optional. Neither or both must be specified. If not specified they are unset.

The \texttt{limit/eradius} keyword is used to restrain electron size from becoming excessively diffuse at very high temperatures were the Gaussian wave packet representation breaks down, and from expanding as free particles to infinite size. If unset, electron radius is free to increase without bounds. If set, a restraining harmonic potential of the form \( E = \frac{1}{2}k_s s^2 \) for \( s > L_{box}/2 \), where \( k_s = 1 \) Hartrees/Bohr^2, is applied on the electron radius.

The \texttt{pressure/evirials} keyword is used to control between two types of pressure computation: if unset, the computed pressure does not include the electronic radial virials contributions to the total pressure (scalar or tensor). If set, the computed pressure will include the electronic radial virial contributions to the total pressure (scalar and tensor).

The \texttt{ecp} keyword is used to associate an ECP representation for a particular atom type. The ECP captures the orbital overlap between a core pseudo particle and valence electrons within the Pauli repulsion. A list of type:element-symbol pairs may be provided for all ECP representations, after the “ecp” keyword.

\textbf{Note:**} Default ECP parameters are provided for C, N, O, Al, and Si. Users can modify these using the \texttt{pair_coeff} command as exemplified above. For this, the User must distinguish between two different functional forms supported, one that captures the orbital overlap assuming the s-type core interacts with an s-like valence electron (s-s) and another that assumes the interaction is s-p. For systems that exhibit significant p-character (e.g. C, N, O) the s-p form is recommended. The “s” ECP form requires 3 parameters and the “p” 5 parameters.

\textbf{Note:**} there are two different pressures that can be reported for eFF when defining this pair_style, one (default) that considers electrons do not contribute radial virial components (i.e. electrons treated as incompressible ‘rigid’ spheres) and one that does. The radial electronic contributions to the virials are only tallied if the flexible pressure option is set, and this will affect both global and per-atom quantities. In principle, the true pressure of a system is somewhere in between the rigid and the flexible eFF pressures, but, for most cases, the difference between these two pressures
will not be significant over long-term averaged runs (i.e. even though the energy partitioning changes, the total energy remains similar).

**Note:** This implementation of eFF gives a reasonably accurate description for systems containing nuclei from Z = 1-6 in “all electron” representations. For systems with increasingly non-spherical electrons, Users should use the ECP representations. ECPs are now supported and validated for most of the second and third row elements of the p-block. Predefined parameters are provided for C, N, O, Al, and Si. The ECP captures the orbital overlap between the core and valence electrons (i.e. Pauli repulsion) with one of the functional forms:

\[ E_{\text{Pauli}}(\text{ECP}_s) = p_1 \exp \left(-\frac{p_2r^2}{p_3 + s^2}\right) \]

\[ E_{\text{Pauli}}(\text{ECP}_p) = p_1 \left(\frac{2}{p_2/s + s/p_2}\right) (r - p_3s)^2 \exp \left[-\frac{p_4 (r - p_3s)^2}{p_5 + s^2}\right] \]

Where the first form correspond to core interactions with s-type valence electrons and the second to core interactions with p-type valence electrons.

The current version adds full support for models with fixed-core and ECP definitions, to enable larger timesteps (i.e. by avoiding the high frequency vibrational modes -translational and radial- of the 2 s electrons), and in the ECP case to reduce the increased orbital complexity in higher Z elements (up to Z<18). A fixed-core should be defined with a mass that includes the corresponding nuclear mass plus the 2 s electrons in atomic mass units (2x5.4857990943e-4), and a radius equivalent to that of minimized 1s electrons (see examples under /examples/USER/eff/fixed-core). An pseudo-core should be described with a mass that includes the corresponding nuclear mass, plus all the core electrons (i.e no outer shell electrons), and a radius equivalent to that of a corresponding minimized full-electron system. The charge for a pseudo-core atom should be given by the number of outer shell electrons.

In general, eFF excels at computing the properties of materials in extreme conditions and tracing the system dynamics over multi-picosecond timescales; this is particularly relevant where electron excitations can change significantly the nature of bonding in the system. It can capture with surprising accuracy the behavior of such systems because it describes consistently and in an unbiased manner many different kinds of bonds, including covalent, ionic, multicenter, ionic, and plasma, and how they interconvert and/or change when they become excited. eFF also excels in computing the relative thermochemistry of isodemic reactions and conformational changes, where the bonds of the reactants are of the same type as the bonds of the products. eFF assumes that kinetic energy differences dominate the overall exchange energy, which is true when the electrons present are nearly spherical and nodeless and valid for covalent compounds such as dense hydrogen, hydrocarbons, and diamond; alkali metals (e.g. lithium), alkali earth metals (e.g. beryllium) and semimetals such as boron; and various compounds containing ionic and/or multicenter bonds, such as boron dihydride.

### 20.80.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \(!= J\), the cutoff distance for the eff/cut style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

The pair_modify shift option is not relevant for these pair styles.

The eff/long (not yet available) style supports the pair_modify table option for tabulation of the short-range portion of the long-range Coulombic interaction.
These pair styles do not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.

### 20.80.5 Restrictions

These pair styles will only be enabled if LAMMPS is built with the USER-EFF package. It will only be enabled if LAMMPS was built with that package. See the [Build package](https://www.lammps.org/doc/Build_package.html) doc page for more info.

These pair styles require that particles store electron attributes such as radius, radial velocity, and radial force, as defined by the `atom_style`. The `electron` atom style does all of this.

These pair styles require you to use the `comm_modify vel yes` command so that velocities are stored by ghost atoms.

pair_coeff * * Na Cl ffield.eim Na Na Na Cl
pair_coeff * * Na Cl ../potentials/ffield.eim Cl NULL Na
```

20.81.3 Description

Style eim computes pairwise interactions for ionic compounds using embedded-ion method (EIM) potentials (Zhou).

The energy of the system $E$ is given by

$$E = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=i+1}^{N} \phi_{ij}(r_{ij}) + \sum_{i=1}^{N} E_i(q_i, \sigma_i)$$

The first term is a double pairwise sum over the J neighbors of all I atoms, where $\phi_{ij}$ is a pair potential. The second term sums over the embedding energy $E_i$ of atom I, which is a function of its charge $q_i$ and the electrical potential $\sigma_i$ at its location. $E_i, q_i,$ and $\sigma_i$ are calculated as

$$q_i = \sum_{j=1}^{N} \eta_{ij}(r_{ij})$$

$$\sigma_i = \sum_{j=1}^{N} q_j \cdot \psi_{ij}(r_{ij})$$

$$E_i(q_i, \sigma_i) = \frac{1}{2} \cdot q_i \cdot \sigma_i$$

where $\eta_{ij}$ is a pairwise function describing electron flow from atom I to atom J, and $\psi_{ij}$ is another pairwise function.

The multi-body nature of the EIM potential is a result of the embedding energy term. A complete list of all the pair functions used in EIM is summarized below

$$\phi_{ij}(r) = \begin{cases} E_b \frac{\beta_{ij} \exp \left(-\alpha_{ij} \frac{r-r_{e,ij}}{r_{c,ij}}\right)}{\beta_{ij}-\alpha_{ij}} - E_b \frac{\beta_{ij} \exp \left(-\beta_{ij} \frac{r-r_{e,ij}}{r_{c,ij}}\right)}{\beta_{ij}-\alpha_{ij}} \cdot fc(r, r_{e,ij}, r_{c,\phi,ij}), & p_{ij} = 1 \\ E_b \frac{\beta_{ij} \exp \left(-\alpha_{ij} \frac{r-r_{e,ij}}{r_{c,ij}}\right)}{\beta_{ij}-\alpha_{ij}} - E_b \frac{\beta_{ij} \exp \left(-\beta_{ij} \frac{r-r_{e,ij}}{r_{c,ij}}\right)}{\beta_{ij}-\alpha_{ij}} \cdot fc(r, r_{e,ij}, r_{c,\phi,ij}), & p_{ij} = 2 \\ \end{cases}$$

$$\eta_{ij} = A_{\phi,ij} (\chi_j - \chi_i) \cdot fc(r, r_{s,\eta,ij}, r_{c,\eta,ij})$$

$$\psi_{ij}(r) = A_{\psi,ij} \exp \left(-\zeta_{ij} r\right) \cdot fc(r, r_{s,\psi,ij}, r_{c,\psi,ij})$$

$$fc(r, r_p, r_c) = 0.510204 \cdot \text{erfc} \left[ \frac{1.64498 (2r - r_p - r_c)}{r_c - r_p} \right] - 0.010204$$

Here $E_b, r_c, r_p(c, \phi), \alpha, \beta, A_{\psi} \chi, r(s, \psi), r(c, \psi), A(\eta), r(s, \eta), r(c, \eta), \chi,$ and pair function type $p$ are parameters, with subscripts $ij$ indicating the two species of atoms in the atomic pair.

**Note:** Even though the EIM potential is treating atoms as charged ions, you should not use a LAMMPS atom_style that stores a charge on each atom and thus requires you to assign a charge to each atom, e.g. the charge or full atom styles. This is because the EIM potential infers the charge on an atom from the equation above for $q_i$; you do not assign charges explicitly.

All the EIM parameters are listed in a potential file which is specified by the pair_coeff command. This is an ASCII text file in a format described below. The “ffield.eim” file included in the “potentials” directory of the LAMMPS
distribution currently includes nine elements Li, Na, K, Rb, Cs, F, Cl, Br, and I. A system with any combination of these elements can be modeled. This file is parameterized in terms of LAMMPS metal units.

Note that unlike other potentials, cutoffs for EIM potentials are not set in the pair_style or pair_coeff command; they are specified in the EIM potential file itself. Likewise, the EIM potential file lists atomic masses; thus you do not need to use the mass command to specify them.

Only a single pair_coeff command is used with the eim style which specifies an EIM potential file and the element(s) to extract information for. The EIM elements are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- Elem1, Elem2, ...
- EIM potential file
- N element names = mapping of EIM elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example like one of those above, suppose you want to model a system with Na and Cl atoms. If your LAMMPS simulation has 4 atom types and you want the first 3 to be Na, and the fourth to be Cl, you would use the following pair_coeff command:

```
pair_coeff * * Na Cl ffield.eim Na Na Na Cl
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The filename is the EIM potential file. The Na and Cl arguments (before the file name) are the two elements for which info will be extracted from the potential file. The first three trailing Na arguments map LAMMPS atom types 1,2,3 to the EIM Na element. The final Cl argument maps LAMMPS atom type 4 to the EIM Cl element.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an eim potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The ffield.eim file in the potentials directory of the LAMMPS distribution is formatted as follows:

Lines starting with # are comments and are ignored by LAMMPS. Lines starting with “global:” include three global values. The first value divides the cations from anions, i.e., any elements with electronegativity above this value are viewed as anions, and any elements with electronegativity below this value are viewed as cations. The second and third values are related to the cutoff function - i.e. the 0.510204, 1.64498, and 0.010204 shown in the above equation can be derived from these values.

Lines starting with “element:” are formatted as follows: name of element, atomic number, atomic mass, electronic negativity, atomic radius (LAMMPS ignores it), ionic radius (LAMMPS ignores it), cohesive energy (LAMMPS ignores it), and q0 (must be 0).

Lines starting with “pair:” are entered as: element 1, element 2, r_(c,phi), r_(c,phi) (redundant for historical reasons), E_b, r_e, alpha, beta, r_(c,eta), A_(eta), r_(s,eta), r_(c,psi), A_(psi), zeta, r_(s,psi), and p.

The lines in the file can be in any order; LAMMPS extracts the info it needs.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.
See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.81.4 Restrictions
This style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package.

pair_coeff * * exp6.params lfluid lfluid polynomial filename 10.0
```
20.82.3 Description

Style \textit{exp6/rx} is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of \( m \) species whose reaction rate kinetics are determined from a set of \( n \) reaction rate equations through the \textit{fix rx} command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. The \textit{exp6/rx} style computes an exponential-6 potential given by

\[ U_{ij}(r) = \frac{\epsilon}{\alpha - 6} \left\{ 6 \exp\left[\alpha(1 - \frac{r_{ij}}{R_m})\right] - \alpha \left(\frac{R_m}{r_{ij}}\right)^6 \right\} \]

where the \( \epsilon \) parameter determines the depth of the potential minimum located at \( R_m \), and \( \alpha \) determines the softness of the repulsion.

The coefficients must be defined for each species in a given particle type via the \textit{pair_coeff} command as in the examples above, where the first argument is the filename that includes the exponential-6 parameters for each species. The file includes the species tag followed by the \( \alpha, \epsilon \) and \( R_m \) parameters. The format of the file is described below.

The second and third arguments specify the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the \textit{fix rx} command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the \textit{fractional} or \textit{molecular} weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).

The fourth argument specifies the type of scaling that will be used to scale the EXP-6 parameters as reactions occur. Currently, there are three scaling options: \textit{exponent}, \textit{polynomial} and \textit{none}.

Exponent scaling requires two additional arguments for scaling the \( R_m \) and \( \epsilon \) parameters, respectively. The scaling factor is computed by \( \phi^{exponent} \), where \( \phi \) is the number of molecules represented by the coarse-grain particle and exponent is specified as a pair coefficient argument for \( R_m \) and \( \epsilon \), respectively. The \( R_m \) and \( \epsilon \) parameters are multiplied by the scaling factor to give the scaled interaction parameters for the CG particle.

Polynomial scaling requires a filename to be specified as a pair coeff argument. The file contains the coefficients to a fifth order polynomial for the \( \alpha, \epsilon \) and \( R_m \) parameters that depend upon \( \phi \) (the number of molecules represented by the CG particle). The format of a polynomial file is provided below.

The \textit{none} option to the scaling does not have any additional pair coeff arguments. This is equivalent to specifying the \textit{exponent} option with \( R_m \) and \( \epsilon \) exponents of 0.0 and 0.0, respectively.

The final argument specifies the interaction cutoff (optional).

The format of a tabulated file is as follows (without the parenthesized comments):

```
# exponential-6 parameters for various species (one or more comment or blank lines)
h2o  exp6  11.00  0.02  3.50  (species, exp6, alpha, Rm, epsilon)
no2  exp6  13.60  0.01  3.70
...  
co2  exp6  13.00  0.03  3.20
```

The format of the polynomial scaling file as follows (without the parenthesized comments):

```
# POLYNOMIAL FILE (one or more comment or blank lines)
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections.

Following a blank line, the next N lines list the species and their corresponding parameters. The first argument is the species tag, the second argument is the exp(6) tag, the third argument is the \( \alpha \) parameter (energy units), the fourth argument is the \( \epsilon \) parameter (energy-distance\(^6\) units), and the fifth argument is the \( R_m \) parameter (distance units). If a species tag of “1fluid” is listed as a pair coefficient, a one-fluid approximation is specified where a concentration-dependent combination of the parameters is computed through the following equations:

\[
R_m^3 = \sum_a \sum_b x_a x_b R_{m,ab}^3
\]

\[
\epsilon = \frac{1}{R_m^3} \sum_a \sum_b x_a x_b \epsilon_{ab} R_{m,ab}^3
\]

\[
\alpha = \frac{1}{\epsilon R_m^3} \sum_a \sum_b x_a x_b \alpha_{ab} \epsilon_{ab} R_{m,ab}^3
\]

where

\[
\epsilon_{ab} = \sqrt{\epsilon_a \epsilon_b}
\]

\[
R_{m,ab} = \frac{R_{m,a} + R_{m,b}}{2}
\]

\[
\alpha_{ab} = \sqrt{\alpha_a \alpha_b}
\]

and \( x_a \) and \( x_b \) are the mole fractions of a and b, respectively, which comprise the gas mixture.

### 20.82.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

This style does not support the pair_modify shift option for the energy of the exp() and 1/r\(^6\) portion of the pair interaction.

This style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure for the A,C terms in the pair interaction.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.
See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.82.5 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

```
20.95.3 Description

These pair styles have a soft repulsive core, tunable by a parameter lambda, in order to avoid singularities during free energy calculations when sites are created or annihilated (Beutler). When lambda tends to 0 the pair interaction vanishes with a soft repulsive core. When lambda tends to 1, the pair interaction approaches the normal, non-soft potential. These pair styles are suited for “alchemical” free energy calculations using the fix adapt/fep and compute fep commands.

The lj/cut/soft style and related sub-styles compute the 12-6 Lennard-Jones and Coulomb potentials modified by a soft core, with the functional form

\[ E = \lambda^n 4\epsilon \left( \frac{1}{\alpha_{\text{LJ}}(1 - \lambda)^2 + \left( \frac{r}{\sigma} \right)^6} \right)^2 - \frac{1}{\alpha_{\text{C}}(1 - \lambda)^2 + \left( \frac{r}{\sigma} \right)^6} \]  

for \( r < r_c \).

The lj/class2/soft style is a 9-6 potential with the exponent of the denominator of the first term in brackets taking the value 1.5 instead of 2 (other details differ, see the form of the potential in pair_style lj/class2).

Coulomb interactions can also be damped with a soft core at short distance,

\[ E = \lambda^n \frac{C q_i q_j}{\epsilon \left[ \alpha_{\text{C}}(1 - \lambda)^2 + r^2 \right]^{1/2}} \]  

for \( r < r_c \).

In the Coulomb part \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, and epsilon is the dielectric constant which can be set by the dielectric command.

The coefficient lambda is an activation parameter. When \( \lambda = 1 \) the pair potential is identical to a Lennard-Jones term or a Coulomb term or a combination of both. When \( \lambda = 0 \) the interactions are deactivated. The transition between these two extrema is smoothed by a soft repulsive core in order to avoid singularities in potential energy and forces when sites are created or annihilated and can overlap (Beutler).

The parameters \( n, \alpha_{\text{LJ}} \) and \( \alpha_{\text{C}} \) are set in the pair_style command, before the cutoffs. Usual choices for the exponent are \( n = 2 \) or \( n = 1 \). For the remaining coefficients \( \alpha_{\text{LJ}} = 0.5 \) and \( \alpha_{\text{C}} = 10 \text{ A}^2 \) are appropriate choices. Plots of the 12-6 LJ and Coulomb terms are shown below, for lambda ranging from 1 to 0 every 0.1.
For the lj/cut/coul/cut/soft or lj/cut/coul/long/soft pair styles, as well as for the equivalent class2 versions, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- $\lambda$ (activation parameter, between 0 and 1)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter two coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style lj/cut/soft, since it has no Coulombic terms. For the coul/cut/soft and coul/long/soft only lambda and the optional cutoff2 are to be specified.
Style \textit{lj/cut/tip4p/long/soft} implements a soft-core version of the TIP4P water model. The usage of the TIP4P pair style is documented in the \textit{pair LJ} styles. In the soft version the parameters \( n \), \( \alpha_{LJ} \) and \( \alpha_C \) are set in the \textit{pair_style} command, after the specific parameters of the TIP4P water model and before the cutoffs. The activation parameter lambda is supplied as an argument of the \textit{pair_coeff} command, after \( \epsilon \) and \( \sigma \) and before the optional cutoffs.

Note: When using the soft-core Coulomb potentials with long-range solvers (\textit{coul/soft}, \textit{lj/cut/coul/long/soft}, etc.) in a free energy calculation in which sites holding electrostatic charges are being created or annihilated (using \textit{fix adapt/fep} and \textit{compute fep}) it is important to adapt both the \( \lambda \) activation parameter (from 0 to 1, or the reverse) and the value of the charge (from 0 to its final value, or the reverse). This ensures that long-range electrostatic terms (kspace) are correct. It is not necessary to use soft-core Coulomb potentials if the van der Waals site is present during the free-energy route, thus avoiding overlap of the charges. Examples are provided in the LAMMPS source directory (kspace) are correct. It is not necessary to use soft-core Coulomb potentials if the van der Waals site is present during the free-energy route, thus avoiding overlap of the charges. Examples are provided in the LAMMPS source directory.

Style \textit{lj/charmm/coul/long/soft} implements a soft-core version of the modified 12-6 LJ potential used in CHARMM and documented in the \textit{pair style} \textit{lj/charmm/coul/long} style. In the soft version the parameters \( n \), \( \alpha_{LJ} \) and \( \alpha_C \) are set in the \textit{pair style} \textit{command}, before the global cutoffs. The activation parameter lambda is introduced as an argument of the \textit{pair style} \textit{command}, after \( \epsilon \) and \( \sigma \) and before the optional cutoffs.

Note: To avoid division by zero do not set \( \sigma = 0 \) in the \textit{lj/cut/soft} and related styles; use the lambda parameter instead to activate/deactivate interactions, or use \( \epsilon = 0 \) and \( \sigma = 1 \). Alternatively, when sites do not interact though the Lennard-Jones term the \textit{coul/long/soft} or similar sub-style can be used via the \textit{pair style hybrid/overlay} command.

The \textit{morse/soft} variant modifies the \textit{pair_morse} style at short range to have a soft core. The functional form differs from that of the \textit{lj/soft} styles, and is instead given by:

\[
s(\lambda) = (1 - \lambda)/(1 - \lambda_f), \quad B = -2De^{-2\alpha r_0}(e^{\alpha r_0} - 1)/3
\]

\[
E = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] + s(\lambda)Be^{-3\alpha(r-r_0)} \quad \lambda \geq \lambda_f \quad r < r_c
\]

\[
E = \left( D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] + Be^{-3\alpha(r-r_0)} \right) (\lambda/\lambda_f)^n \quad \lambda < \lambda_f \quad r < r_c
\]

The \textit{morse/soft} style requires the following pair coefficients:

- \( D_0 \) (energy units)
- \( \alpha \) (1/distance units)
- \( r_0 \) (distance units)
- \( \lambda \) (unitless, between 0.0 and 1.0)
- cutoff (distance units)
The last coefficient is optional. If not specified, the global morse cutoff is used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.95.4 Mixing, shift, table, tail correction, restart, rRESPA info

The different versions of the lj/cut/soft pair styles support mixing. For atom type pairs I,J and I != J, the $\epsilon$ and $\sigma$ coefficients and cutoff distance for these pair style can be mixed. The default mix value is geometric for 12-6 styles.

The mixing rule for epsilon and sigma for lj/class2/soft 9-6 potentials is to use the sixthpower formulas. The pair_modify mix setting is thus ignored for class2 potentials for $\epsilon$ and $\sigma$. However it is still followed for mixing the cutoff distance. See the pair_modify command for details.

The morse/soft pair style does not support mixing. Thus, coefficients for all LJ pairs must be specified explicitly.

All of the pair styles with soft core support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction.

The different versions of the lj/cut/soft pair styles support the pair_modify tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

**Note:** The analytical form of the tail corrections for energy and pressure used in the lj/cut/soft potentials are approximate, being identical to that of the corresponding non-soft potentials scaled by a factor $\lambda^n$. The errors due to this approximation should be negligible. For example, for a cutoff of 2.5$\sigma$ this approximation leads to maximum relative errors in tail corrections of the order of 1e-4 for energy and virial ($\alpha_{lj} = 0.5, n = 2$). The error vanishes when lambda approaches 0 or 1. Note that these are the errors affecting the long-range tail (itself a correction to the interaction energy) which includes other approximations, namely that the system is homogeneous (local density equal the average density) beyond the cutoff.

The morse/soft pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

All of these pair styles write information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.
20.95.5 Restrictions

The pair styles with soft core are only enabled if LAMMPS was built with the USER-FEP package. The long versions also require the KSPACE package to be installed. The soft tip4p versions also require the MOLECULE package to be installed. These styles are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

20.95.7 Default

none

20.96 pair_style gauss command

Accelerator Variants: gauss/gpu, gauss/omp

20.97 pair_style gauss/cut command

Accelerator Variants: gauss/cut/omp

20.97.1 Syntax

```
pair_style gauss cutoff
pair_style gauss/cut cutoff
```

- cutoff = global cutoff for Gauss interactions (distance units)

20.97.2 Examples

```
pair_style gauss 12.0
pair_coeff * * 1.0 0.9
pair_coeff 1 4 1.0 0.9 10.0

pair_style gauss/cut 3.5
pair_coeff 1 4 0.2805 1.45 0.112
```
20.97.3 Description

Style \textit{gauss} computes a tethering potential of the form

\[ E = -A \exp(-Br^2) \quad r < r_c \]

between an atom and its corresponding tether site which will typically be a frozen atom in the simulation. \( r_c \) is the cutoff.

The following coefficients must be defined for each pair of atom types via the \textit{pair_coeff} command as in the examples above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands:

- A (energy units)
- B (1/distance^2 units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

Style \textit{gauss/cut} computes a generalized Gaussian interaction potential between pairs of particles:

\[ E = \frac{H}{\sigma_h \sqrt{2\pi}} \exp \left[ -\frac{(r - r_{mh})^2}{2\sigma_h^2} \right] \]

where H determines together with the standard deviation \( \sigma_h \) the peak height of the Gaussian function, and \( r_{mh} \) the peak position. Examples of the use of the Gaussian potentials include implicit solvent simulations of salt ions (Lenart) and of surfactants (Jusufi). In these instances the Gaussian potential mimics the hydration barrier between a pair of particles. The hydration barrier is located at \( r_{mh} \) and has a width of \( \sigma_h \). The prefactor determines the height of the potential barrier.

The following coefficients must be defined for each pair of atom types via the \textit{pair_coeff} command as in the example above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands:

- H (energy * distance units)
- \( r_{mh} \) (distance units)
- \( \sigma_h \) (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix command-line switch} when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.
20.97.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I ≠ J, the A, B, H, sigma_h, r_mh parameters, and the cutoff distance for these pair styles can be mixed: A (energy units) sqrt(1/B) (distance units, see below) H (energy units) sigma_h (distance units) r_mh (distance units) cutoff (distance units):

The default mix value is geometric. Only arithmetic and geometric mix values are supported. See the “pair_modify” command for details.

The A and H parameters are mixed using the same rules normally used to mix the “epsilon” parameter in a Lennard Jones interaction. The sigma_h, r_mh, and the cutoff distance are mixed using the same rules used to mix the “sigma” parameter in a Lennard Jones interaction. The B parameter is converted to a distance (sigma), before mixing (using sigma=B^-0.5), and converted back to a coefficient afterwards (using B=sigma^2). Negative A values are converted to positive A values (using abs(A)) before mixing, and converted back after mixing (by multiplying by min(sign(Ai),sign(Aj))). This way, if either particle is repulsive (if Ai<0 or Aj<0), then the default interaction between both particles will be repulsive.

The gauss style does not support the pair_modify shift option. There is no effect due to the Gaussian well beyond the cutoff; hence reasonable cutoffs need to be specified.

The gauss/cut style supports the pair_modify shift option for the energy of the Gauss-potential portion of the pair interaction.

The pair_modify table and tail options are not relevant for these pair styles.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

The gauss pair style tallies an “occupancy” count of how many Gaussian-well sites have an atom within the distance at which the force is a maximum = sqrt(0.5/b). This quantity can be accessed via the compute pair command as a vector of values of length 1.

To print this quantity to the log file (with a descriptive column heading) the following commands could be included in an input script:

```
compute gauss all pair gauss
variable occ equal c_gauss[1]
thermo_style custom step temp epair v_occ
```

20.97.5 Restrictions

The gauss/cut style is part of the USER-MISC package. It is only enabled if LAMMPS is build with that package. See the Build package doc page for more info.

The gauss style does not apply special_bonds factors. When using this pair style on a system that has bonds, the special_bonds factors, if using the default setting of 0.0, may need to be adjusted to some very small number (e.g. 1.0e-100), so that those special pairs are not completely excluded from the neighbor lists, but won’t contribute forces or energies from styles (e.g. when used in combination with a hybrid pair style) that do apply those factors.
20.97.6 Related commands

pair_coeff, pair_style coul/diel

20.97.7 Default

none

20.98 pair_style gayberne command

Accelerator Variants: gayberne/gpu, gayberne/intel, gayberne/omp

20.98.1 Syntax

```plaintext
pair_style gayberne gamma upsilon mu cutoff
```

- gamma = shift for potential minimum (typically 1)
- upsilon = exponent for eta orientation-dependent energy function
- mu = exponent for chi orientation-dependent energy function
- cutoff = global cutoff for interactions (distance units)

20.98.2 Examples

```plaintext
pair_style gayberne 1.0 1.0 1.0 10.0
pair_coeff * * 1.0 1.7 1.7 3.4 3.4 1.0 1.0 1.0
```

20.98.3 Description

The `gayberne` styles compute a Gay-Berne anisotropic LJ interaction (Berardi) between pairs of ellipsoidal particles or an ellipsoidal and spherical particle via the formulas

\[
U(A_1, A_2, r_{12}) = U_r(A_1, A_2, r_{12}, \gamma) \cdot \eta_{12}(A_1, A_2, \nu) \cdot \chi_{12}(A_1, A_2, r_{12}, \mu)
\]

\[
U_r = 4\epsilon(\varrho^{12} - \varrho^6)
\]

\[
\varrho = \frac{\sigma}{h_{12} + \gamma\sigma}
\]

where \(A_1\) and \(A_2\) are the transformation matrices from the simulation box frame to the body frame and \(r_{12}\) is the center to center vector between the particles. \(U_r\) controls the shifted distance dependent interaction based on the distance of closest approach of the two particles \((h_{12})\) and the user-specified shift parameter gamma. When both particles are spherical, the formula reduces to the usual Lennard-Jones interaction (see details below for when Gay-Berne treats a particle as “spherical”).
For large uniform molecules it has been shown that the energy parameters are approximately representable in terms of local contact curvatures (Everaers):

\[
\epsilon_a = \sigma \cdot \frac{a}{b \cdot c}; \epsilon_b = \sigma \cdot \frac{b}{a \cdot c}; \epsilon_c = \sigma \cdot \frac{c}{a \cdot b}
\]

The variable names utilized as potential parameters are for the most part taken from (Everaers) in order to be consistent with the RE-squared pair potential. Details on the upsilon and mu parameters are given here.

More details of the Gay-Berne formulation are given in the references listed below and in this supplementary document.

Use of this pair style requires the NVE, NVT, or NPT fixes with the *asphere* extension (e.g. *fix nve/asphere*) in order to integrate particle rotation. Additionally, *atom_style ellipsoid* should be used since it defines the rotational state and the size and shape of each ellipsoidal particle.

The following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands, or by mixing as described below:

- \( \epsilon \) = well depth (energy units)
- \( \sigma \) = minimum effective particle radii (distance units)
- \( \epsilon_{i,a} \) = relative well depth of type I for side-to-side interactions
- \( \epsilon_{i,b} \) = relative well depth of type I for face-to-face interactions
- \( \epsilon_{i,c} \) = relative well depth of type I for end-to-end interactions
- \( \epsilon_{j,a} \) = relative well depth of type J for side-to-side interactions
- \( \epsilon_{j,b} \) = relative well depth of type J for face-to-face interactions
- \( \epsilon_{j,c} \) = relative well depth of type J for end-to-end interactions
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff specified in the *pair_style* command is used.

It is typical with the Gay-Berne potential to define \( \sigma \) as the minimum of the 3 shape diameters of the particles involved in an I,I interaction, though this is not required. Note that this is a different meaning for \( \sigma \) than the *pair_style resquared* potential uses.

The \( \epsilon_i \) and \( \epsilon_j \) coefficients are actually defined for atom types, not for pairs of atom types. Thus, in a series of *pair_coeff* commands, they only need to be specified once for each atom type.

Specifically, if any of \( \epsilon_{i,a}, \epsilon_{i,b}, \epsilon_{i,c} \) are non-zero, the three values are assigned to atom type I. If all the \( \epsilon_i \) values are zero, they are ignored. If any of \( \epsilon_{j,a}, \epsilon_{j,b}, \epsilon_{j,c} \) are non-zero, the three values are assigned to atom type J. If all three epsilon_j values are zero, they are ignored. Thus the typical way to define the \( \epsilon_i \) and \( \epsilon_j \) coefficients is to list their values in “pair_coeff I J” commands when I = J, but set them to 0.0 when I != J. If you do list them when I != J, you should insure they are consistent with their values in other pair_coeff commands, since only the last setting will be in effect.

Note that if this potential is being used as a sub-style of *pair_style hybrid*, and there is no “pair_coeff I I” setting made for Gay-Berne for a particular type I (because I-I interactions are computed by another hybrid pair potential), then you still need to insure the \( \epsilon \) a,b,c coefficients are assigned to that type. e.g. in a “pair_coeff I J” command.

**Note:** If the \( \epsilon_a = b = c \) for an atom type, and if the shape of the particle itself is spherical, meaning its 3 shape parameters are all the same, then the particle is treated as an LJ sphere by the Gay-Berne potential. This is significant because if two LJ spheres interact, then the simple Lennard-Jones formula is used to compute their interaction energy/force using the specified epsilon and sigma as the standard LJ parameters. This is much cheaper to compute than the full Gay-Berne formula. To treat the particle as a LJ sphere with sigma = D, you should normally set \( \epsilon = a = b = c = 1.0 \), set
the pair_coeff \( \sigma = D \), and also set the 3 shape parameters for the particle to D. The one exception is that if the 3 shape parameters are set to 0.0, which is a valid way in LAMMPS to specify a point particle, then the Gay-Berne potential will treat that as shape parameters of 1.0 (i.e. a LJ particle with \( \sigma = 1 \)), since it requires finite-size particles. In this case you should still set the pair_coeff \( \sigma \) to 1.0 as well.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix} command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.98.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \(!= J\), the epsilon and sigma coefficients and cutoff distance for this pair style can be mixed. The default mix value is \textit{geometric}. See the \textit{pair_modify} command for details.

This pair styles supports the \textit{pair_modify} shift option for the energy of the Lennard-Jones portion of the pair interaction, but only for sphere-sphere interactions. There is no shifting performed for ellipsoidal interactions due to the anisotropic dependence of the interaction.

The \textit{pair_modify} table option is not relevant for this pair style.

This pair style does not support the \textit{pair_modify} tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to \textit{binary restart files}, so \textit{pair_style} and \textit{pair_coeff} commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the \textit{pair} keyword of the \textit{run_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

### 20.98.5 Restrictions

The \textit{gayberne} style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair style require that atoms store torque and a quaternion to represent their orientation, as defined by the \textit{atom_style}. It also require they store a per-type \textit{shape}. The particles cannot store a per-particle diameter.

This pair style requires that atoms be ellipsoids as defined by the \textit{atom_style ellipsoid} command.

Particles acted on by the potential can be finite-size aspherical or spherical particles, or point particles. Spherical particles have all 3 of their shape parameters equal to each other. Point particles have all 3 of their shape parameters equal to 0.0.

The Gay-Berne potential does not become isotropic as r increases (Everaers). The distance-of-closest-approach approximation used by LAMMPS becomes less accurate when high-aspect ratio ellipsoids are used.

20.101.1 Syntax

pair_style style Kn Kt gamma_n gamma_t xmu dampflag

- style = gran/hooke or gran/hooke/history or gran/hertz/history
- Kn = elastic constant for normal particle repulsion (force/distance units or pressure units - see discussion below)
- Kt = elastic constant for tangential contact (force/distance units or pressure units - see discussion below)
- gamma_n = damping coefficient for collisions in normal direction (1/time units or 1/time-distance units - see discussion below)
- gamma_t = damping coefficient for collisions in tangential direction (1/time units or 1/time-distance units - see discussion below)
- xmu = static yield criterion (unitless value between 0.0 and 1.0e4)
- dampflag = 0 or 1 if tangential damping force is excluded or included
**Note:** Versions of LAMMPS before 9Jan09 had different style names for granular force fields. This is to emphasize the fact that the Hertzian equation has changed to model polydispersity more accurately. A side effect of the change is that the \( K_n, K_t, \gamma_n, \) and \( \gamma_t \) coefficients in the pair_style command must be specified with different values in order to reproduce calculations made with earlier versions of LAMMPS, even for monodisperse systems. See the NOTE below for details.

20.101.2 Examples

```
pair_style gran/hooke/history 200000.0 NULL 50.0 NULL 0.5 1
pair_style gran/hooke 200000.0 70000.0 50.0 30.0 0.5 0
```

20.101.3 Description

The `gran` styles use the following formulas for the frictional force between two granular particles, as described in (Brilliantov), (Silbert), and (Zhang), when the distance \( r \) between two particles of radii \( R_i \) and \( R_j \) is less than their contact distance \( d = R_i + R_j \). There is no force between the particles when \( r > d \).

The two Hookean styles use this formula:

\[
F_{hk} = (k_n \delta n_{ij} - m_{eff} \gamma_n v_n) - (k_t \Delta s_t + m_{eff} \gamma_t v_t)
\]

The Hertzian style uses this formula:

\[
F_{hz} = \sqrt{\delta} \sqrt{\frac{R_i R_j}{R_i + R_j}} F_{hk} = \sqrt{\delta} \sqrt{\frac{R_i R_j}{R_i + R_j}} \left[ (k_n \delta n_{ij} - m_{eff} \gamma_n v_n) - (k_t \Delta s_t + m_{eff} \gamma_t v_t) \right]
\]

In both equations the first parenthesized term is the normal force between the two particles and the second parenthesized term is the tangential force. The normal force has 2 terms, a contact force and a damping force. The tangential force also has 2 terms: a shear force and a damping force. The shear force is a “history” effect that accounts for the tangential displacement between the particles for the duration of the time they are in contact. This term is included in pair styles hooke/history and hertz/history, but is not included in pair style hooke. The tangential damping force term is included in all three pair styles if dampflag is set to 1; it is not included if dampflag is set to 0.

The other quantities in the equations are as follows:

- \( \delta = d - r = \) overlap distance of 2 particles
- \( K_n = \) elastic constant for normal contact
- \( K_t = \) elastic constant for tangential contact
- \( \gamma_n = \) viscoelastic damping constant for normal contact
- \( \gamma_t = \) viscoelastic damping constant for tangential contact
- \( m_{eff} = M_i M_j / (M_i + M_j) = \) effective mass of 2 particles of mass \( M_i \) and \( M_j \)
- \( \Delta s_t = \) tangential displacement vector between 2 particles which is truncated to satisfy a frictional yield criterion
- \( n_{ij} = \) unit vector along the line connecting the centers of the 2 particles
- \( V_n = \) normal component of the relative velocity of the 2 particles
- \( V_t = \) tangential component of the relative velocity of the 2 particles
The $K_n$, $K_t$, $\gamma_n$, and $\gamma_t$ coefficients are specified as parameters to the pair_style command. If a NULL is used for $K_t$, then a default value is used where $K_t = 2/7K_n$. If a NULL is used for $\gamma_n$, then a default value is used where $\gamma_t = 1/2\gamma_n$.

The interpretation and units for these 4 coefficients are different in the Hookean versus Hertzian equations.

The Hookean model is one where the normal push-back force for two overlapping particles is a linear function of the overlap distance. Thus the specified $K_n$ is in units of (force/distance). Note that this push-back force is independent of absolute particle size (in the monodisperse case) and of the relative sizes of the two particles (in the polydisperse case). This model also applies to the other terms in the force equation so that the specified $\gamma_n$ is in units of (1/time), $K_t$ is in units of (force/distance), and $\gamma_t$ is in units of (1/time).

The Hertzian model is one where the normal push-back force for two overlapping particles is proportional to the area of overlap of the two particles, and is thus a non-linear function of overlap distance. Thus $K_n$ has units of force per area and is thus specified in units of (pressure). The effects of absolute particle size (monodispersity) and relative size (polydispersity) are captured in the radii-dependent pre-factors. When these pre-factors are carried through to the other terms in the force equation it means that the specified $\gamma_n$ is in units of (1/time*distance), $K_t$ is in units of (pressure), and $\gamma_t$ is in units of (1/time*distance)).

Note that in the Hookean case, $K_n$ can be thought of as a linear spring constant with units of force/distance. In the Hertzian case, $K_n$ is like a non-linear spring constant with units of force/area or pressure, and as shown in the (Zhang) paper, $K_n = 4G/(3(1 - \nu))$ where $\nu$ = the Poisson ratio, $G$ = shear modulus = $E/(2(1 + \nu))$, and $E$ = Young’s modulus. Similarly, $K_t = 4G/(2 - \nu)$. (NOTE: in an earlier version of the manual, we incorrectly stated that $K_t = 8G/(2 - \nu)$.)

Thus in the Hertzian case $K_n$ and $K_t$ can be set to values that corresponds to properties of the material being modeled. This is also true in the Hookean case, except that a spring constant must be chosen that is appropriate for the absolute size of particles in the model. Since relative particle sizes are not accounted for, the Hookean styles may not be a suitable model for polydispers systems.

Note: In versions of LAMMPS before 9Jan09, the equation for Hertzian interactions did not include the $\sqrt{r_ir_j/(r_i + r_j)}$ term and thus was not as accurate for polydispers systems. For monodisperse systems, $\sqrt{r_ir_j/(r_i + r_j)}$ is a constant factor that effectively scales all 4 coefficients: $K_n, K_t, \gamma_n, \gamma_t$. Thus you can set the values of these 4 coefficients appropriately in the current code to reproduce the results of a previous Hertzian monodisperse calculation. For example, for the common case of a monodisperse system with particles of diameter 1, all 4 of these coefficients should now be set 2x larger than they were previously.

Xmu is also specified in the pair_style command and is the upper limit of the tangential force through the Coulomb criterion $F_t = xmu*F_n$, where $F_t$ and $F_n$ are the total tangential and normal force components in the formulas above. Thus in the Hookean case, the tangential force between 2 particles grows according to a tangential spring and dash-pot model until $F_t/F_n = xmu$ and is then held at $F_t = F_n*xmu$ until the particles lose contact. In the Hertzian case, a similar analogy holds, though the spring is no more longer linear.

Note: Normally, $xmu$ should be specified as a fractional value between 0.0 and 1.0, however LAMMPS allows large values (up to 1.0e4) to allow for modeling of systems which can sustain very large tangential forces.

The effective mass $m_{eff}$ is given by the formula above for two isolated particles. If either particle is part of a rigid body, its mass is replaced by the mass of the rigid body in the formula above. This is determined by searching for a fix rigid command (or its variants).

For granular styles there are no additional coefficients to set for each pair of atom types via the pair_coeff command. All settings are global and are made via the pair_style command. However you must still use the pair_coeff for all pairs of granular atom types. For example the command
LAMMPS Documentation

pair_coeff

should be used if all atoms in the simulation interact via a granular potential (i.e. one of the pair styles above is used).
If a granular potential is used as a sub-style of pair_style hybrid, then specific atom types can be used in the pair_coeff command to determine which atoms interact via a granular potential.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.
See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.101.4 Mixing, shift, table, tail correction, restart, rRESPA info

The pair_modify mix, shift, table, and tail options are not relevant for granular pair styles.

These pair styles write their information to binary restart files, so a pair_style command does not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

The single() function of these pair styles returns 0.0 for the energy of a pairwise interaction, since energy is not conserved in these dissipative potentials. It also returns only the normal component of the pairwise interaction force. However, the single() function also calculates 10 extra pairwise quantities. The first 3 are the components of the tangential force between particles I and J, acting on particle I. The fourth is the magnitude of this tangential force. The next 3 (5-7) are the components of the relative velocity in the normal direction (along the line joining the 2 sphere centers). The last 3 (8-10) the components of the relative velocity in the tangential direction.

These extra quantities can be accessed by the compute pair/local command, as p1, p2, . . . , p10.

20.101.5 Restrictions

All the granular pair styles are part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair styles require that atoms store torque and angular velocity (omega) as defined by the atom_style. They also require a per-particle radius is stored. The sphere atom style does all of this.

This pair style requires you to use the comm_modify vel yes command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the read_restart command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the read_restart command for more details.

```
20.102.3 Description

The granular styles support a variety of options for the normal, tangential, rolling and twisting forces resulting from contact between two granular particles. This expands on the options offered by the pair gran/* pair styles. The total computed forces and torques are the sum of various models selected for the normal, tangential, rolling and twisting modes of motion.

All model choices and parameters are entered in the pair_coeff command, as described below. Unlike e.g. pair gran/hooke, coefficient values are not global, but can be set to different values for different combinations of particle types, as determined by the pair_coeff command. If the contact model choice is the same for two particle types, the mixing for the cross-coefficients can be carried out automatically. This is shown in the last example, where model choices are the same for type 1 - type 1 as for type 2 - type2 interactions, but coefficients are different. In this case, the mixed coefficients for type 1 - type 2 interactions can be determined from mixing rules discussed below. For additional flexibility, coefficients as well as model forms can vary between particle types, as shown in the fourth example: type 1 - type 1 interactions are based on a Johnson-Kendall-Roberts normal contact model and 2-2 interactions are based on a DMT cohesive model (see below). In that example, 1-1 and 2-2 interactions have different model forms, in which case mixing of coefficients cannot be determined, so 1-2 interactions must be explicitly defined via the pair_coeff 1 * command, otherwise an error would result.

The first required keyword for the pair_coeff command is the normal contact model. Currently supported options for normal contact models and their required arguments are:

1. hooke : \( k_n, \eta_{n0} \) (or \( e \))
2. hertz : \( k_n, \eta_{n0} \) (or \( e \))
3. hertz/material : \( E, \eta_{n0} \) (or \( e \)), \( \nu \)
4. dmt : \( E, \eta_{n0} \) (or \( e \)), \( \nu, \gamma \)
5. jkr : \( E, \eta_{n0} \) (or \( e \)), \( \nu, \gamma \)

Here, \( k_n \) is spring stiffness (with units that depend on model choice, see below); \( \eta_{n0} \) is a damping prefactor (or, in its place a coefficient of restitution \( e \), depending on the choice of damping mode, see below); \( E \) is Young’s modulus in units of \( \text{force} / \text{length}^2 \), i.e. pressure; \( \nu \) is Poisson’s ratio and \( \gamma \) is a surface energy density, in units of \( \text{energy} / \text{length}^2 \).

For the hooke model, the normal, elastic component of force acting on particle \( i \) due to contact with particle \( j \) is given by:

\[
F_{ne,\text{Hooke}} = k_n \delta_{ij} n
\]

Where \( \delta_{ij} = R_i + R_j - \| r_{ij} \| \) is the particle overlap, \( R_i, R_j \) are the particle radii, \( r_{ij} = r_i - r_j \) is the vector separating the two particle centers (note the i-j ordering so that \( F_{ne} \) is positive for repulsion), and \( n = r_{ij} / \| r_{ij} \| \). Therefore, for hooke, the units of the spring constant \( k_n \) are force/length, or equivalently mass/time/\( \text{length}^3 \).

For the hertz model, the normal component of force is given by:

\[
F_{ne,\text{Hertz}} = k_n R_{eff}^{1/2} \delta_{ij}^{3/2} n
\]

Here, \( R_{eff} = \frac{R_i R_j}{R_i + R_j} \) is the effective radius, denoted for simplicity as \( R \) from here on. For hertz, the units of the spring constant \( k_n \) are force/length^2, or equivalently pressure.

For the hertz/material model, the force is given by:

\[
F_{ne,\text{Hertz/material}} = \frac{4}{3} E_{eff} R_{eff}^{1/2} \delta_{ij}^{3/2} n
\]

Here, \( E_{eff} = E = \left( \frac{1-\nu_i^2}{E_i} + \frac{1-\nu_j^2}{E_j} \right)^{-1} \) is the effective Young’s modulus, with \( \nu_i, \nu_j \) the Poisson ratios of the particles of types \( i \) and \( j \). Note that if the elastic modulus and the shear modulus of the two particles are the same, the hertz/material model is equivalent to the hertz model with \( k_n = 4/3 E_{eff} \).
The *dmt* model corresponds to the *(Derjaguin-Muller-Toporov)* cohesive model, where the force is simply Hertz with an additional attractive cohesion term:

\[ F_{ne,dmt} = \left( \frac{4}{3} ER^{1/2} \delta_{ij}^{3/2} - 4\pi\gamma R \right) n \]

The *jkr* model is the *(Johnson-Kendall-Roberts)* model, where the force is computed as:

\[ F_{ne,jkr} = \left( \frac{4Ea^3}{3R^2} - 2\pi a^2 \sqrt{\frac{4\gamma E}{\pi a}} \right) n \]

Here, \( a \) is the radius of the contact zone, related to the overlap \( \delta \) according to:

\[ \delta = a^2 / R - 2\sqrt{\pi\gamma a / E} \]

LAMMPS internally inverts the equation above to solve for \( a \) in terms of \( \delta \), then solves for the force in the previous equation. Additionally, note that the JKR model allows for a tensile force beyond contact (i.e. for \( \delta < 0 \)), up to a maximum of \( 3\pi\gamma R \) (also known as the ‘pull-off’ force). Note that this is a hysteretic effect, where particles that are not contacting initially will not experience force until they come into contact \( \delta \geq 0 \); as they move apart and \( (\delta < 0) \), they experience a tensile force up to \( 3\pi\gamma R \), at which point they lose contact.

In addition, the normal force is augmented by a damping term of the following general form:

\[ F_{n,damp} = -\eta_n v_{n,rel} \]

Here, \( v_{n,rel} = (v_j - v_i) \cdot n \) \( n \) is the component of relative velocity along \( n \).

The optional *damping* keyword to the *pair_coeff* command followed by a keyword determines the model form of the damping factor \( \eta_n \), and the interpretation of the \( \eta_{n0} \) or \( c \) coefficients specified as part of the normal contact model settings. The *damping* keyword and corresponding model form selection may be appended anywhere in the *pair coeff* command. Note that the choice of damping model affects both the normal and tangential damping (and depending on other settings, potentially also the twisting damping). The options for the damping model currently supported are:

1. *velocity*
2. *mass_velocity*
3. *viscoelastic*
4. *tsuji*

If the *damping* keyword is not specified, the *viscoelastic* model is used by default.

For *damping velocity*, the normal damping is simply equal to the user-specified damping coefficient in the *normal* model:

\[ \eta_n = \eta_{n0} \]

Here, \( \eta_{n0} \) is the damping coefficient specified for the normal contact model, in units of *mass/time*.

For *damping mass_velocity*, the normal damping is given by:

\[ \eta_n = \eta_{n0} m_{eff} \]

Here, \( \eta_{n0} \) is the damping coefficient specified for the normal contact model, in units of *mass/time* and \( m_{eff} = m_i m_j / (m_i + m_j) \) is the effective mass. Use *damping mass_velocity* to reproduce the damping behavior of *pair gran/hooke/*.
The damping viscoelastic model is based on the viscoelastic treatment of (Brilliantov et al), where the normal damping is given by:

\[ \eta_n = \eta_{n0} \text{am} \text{eff} \]

Here, \( a \) is the contact radius, given by \( a = \sqrt{R\delta} \) for all models except jkr, for which it is given implicitly according to \( \delta = a^2/R - 2\pi\gamma a/E \). For damping viscoelastic, \( \eta_{n0} \) is in units of \((\text{time} \times \text{distance})^{-1}\).

The tsuji model is based on the work of (Tsuji et al). Here, the damping coefficient specified as part of the normal model is interpreted as a restitution coefficient \( e \). The damping constant \( \eta_n \) is given by:

\[ \eta_n = \alpha (m_{eff} k_n)^{1/2} \]

For normal contact models based on material parameters, \( k_n = 4/3Ea \). The parameter \( \alpha \) is related to the restitution coefficient \( e \) according to:

\[ \alpha = 1.2728 - 4.2783e + 11.087e^2 - 22.348e^3 + 27.467e^4 - 18.022e^5 + 4.8218e^6 \]

The dimensionless coefficient of restitution \( e \) specified as part of the normal contact model parameters should be between 0 and 1, but no error check is performed on this.

The total normal force is computed as the sum of the elastic and damping components:

\[ F_n = F_{ne} + F_{n,damp} \]

The pair_coeff command also requires specification of the tangential contact model. The required keyword tangential is expected, followed by the model choice and associated parameters. Currently supported tangential model choices and their expected parameters are as follows:

1. linear_nohistory : \( x_{\gamma,t}, \mu_s \)
2. linear_history : \( k_t, x_{\gamma,t}, \mu_s \)
3. mindlin : \( k_t \) or NULL, \( x_{\gamma,t}, \mu_s \)
4. mindlin/force : \( k_t \) or NULL, \( x_{\gamma,t}, \mu_s \)
5. mindlin_rescale : \( k_t \) or NULL, \( x_{\gamma,t}, \mu_s \)
6. mindlin_rescale/force : \( k_t \) or NULL, \( x_{\gamma,t}, \mu_s \)

Here, \( x_{\gamma,t} \) is a dimensionless multiplier for the normal damping \( \eta_n \) that determines the magnitude of the tangential damping, \( \mu_t \) is the tangential (or sliding) friction coefficient, and \( k_t \) is the tangential stiffness coefficient.

For tangential linear_nohistory, a simple velocity-dependent Coulomb friction criterion is used, which mimics the behavior of the pair gran/hooke style. The tangential force \( F_t \) is given by:

\[ F_t = -\min(\mu_tF_{n0}, ||F_{t,damp}||)t \]

The tangential damping force \( F_{t,damp} \) is given by:

\[ F_{t,damp} = -\eta_t v_{t,rel} \]

The tangential damping prefactor \( \eta_t \) is calculated by scaling the normal damping \( \eta_n \) (see above):

\[ \eta_t = -x_{\gamma,t}\eta_n \]

The normal damping prefactor \( \eta_n \) is determined by the choice of the damping keyword, as discussed above. Thus, the damping keyword also affects the tangential damping. The parameter \( x_{\gamma,t} \) is a scaling coefficient. Several works in
the literature use $x_{\gamma, t} = 1$ (Marshall, Tsuji et al, Silbert et al). The relative tangential velocity at the point of contact is given by $\mathbf{v}_{t,rel} = \mathbf{v}_t - (R_i \Omega_i + R_j \Omega_j) \times \mathbf{n}$, where $\mathbf{v}_t = \mathbf{v}_r - \mathbf{v}_r \cdot \mathbf{n}$, $\mathbf{v}_r = \mathbf{v}_j - \mathbf{v}_i$. The direction of the applied force is $\mathbf{t} = \mathbf{v}_{t,rel}/\|\mathbf{v}_{t,rel}\|$. The normal force value $F_{n0}$ used to compute the critical force depends on the form of the contact model. For non-cohesive models (hertz, hertz/material, hook), it is given by the magnitude of the normal force:

$$F_{n0} = \|\mathbf{F}_n\|$$

For cohesive models such as jkr and dmt, the critical force is adjusted so that the critical tangential force approaches $\mu_t F_{pulloff}$, see Marshall, equation 43, and Thornton. For both models, $F_{n0}$ takes the form:

$$F_{n0} = \|\mathbf{F}_{ne} + 2F_{pulloff}\|$$

Where $F_{pulloff} = 3\pi \gamma R$ for jkr, and $F_{pulloff} = 4\pi \gamma R$ for dmt.

The remaining tangential options all use accumulated tangential displacement (i.e. contact history), except for the options mindlin/force and mindlin_rescale/force, that use accumulated tangential force instead, and are discussed further below. The accumulated tangential displacement is discussed in details below in the context of the linear_history option. The same treatment of the accumulated displacement applies to the other options as well.

For tangential linear_history, the tangential force is given by:

$$\mathbf{F}_t = -\min(\mu_t F_{n0}, \|-k_t \xi + \mathbf{F}_{t,damp}\|) \mathbf{t}$$

Here, $\xi$ is the tangential displacement accumulated during the entire duration of the contact:

$$\xi = \int_{t_0}^{t} \mathbf{v}_{t,rel}(\tau) d\tau$$

This accumulated tangential displacement must be adjusted to account for changes in the frame of reference of the contacting pair of particles during contact. This occurs due to the overall motion of the contacting particles in a rigid-body-like fashion during the duration of the contact. There are two modes of motion that are relevant: the ‘tumbling’ rotation of the contacting pair, which changes the orientation of the plane in which tangential displacement occurs; and ‘spinning’ rotation of the contacting pair about the vector connecting their centers of mass ($\mathbf{n}$). Corrections due to the former mode of motion are made by rotating the accumulated displacement into the plane that is tangential to the contact vector at each step, or equivalently removing any component of the tangential displacement that lies along $\mathbf{n}$, and rescaling to preserve the magnitude. This follows the discussion in Luding, see equation 17 and relevant discussion in that work:

$$\xi = (\xi' - (\mathbf{n} \cdot \xi') \mathbf{n}) \frac{\|\xi'\|}{\|\xi' - (\mathbf{n} \cdot \xi') \mathbf{n}\|}$$

Here, $\xi'$ is the accumulated displacement prior to the current time step and $\xi$ is the corrected displacement. Corrections to the displacement due to the second mode of motion described above (rotations about $\mathbf{n}$) are not currently implemented, but are expected to be minor for most simulations.

Furthermore, when the tangential force exceeds the critical force, the tangential displacement is re-scaled to match the value for the critical force (see Luding, equation 20 and related discussion):

$$\xi = -\frac{1}{k_t} (\mu_t F_{n0} \mathbf{t} - \mathbf{F}_{t,damp})$$

The tangential force is added to the total normal force (elastic plus damping) to produce the total force on the particle. The tangential force also acts at the contact point (defined as the center of the overlap region) to induce a torque on each particle according to:

$$\tau = -(R_i - 0.5\delta) \mathbf{n} \times \mathbf{F}_t$$
\[ \tau_j = -(R_j - 0.5\delta) \mathbf{n} \times \mathbf{F}_t \]

For *tangential mindlin*, the *Mindlin* no-slip solution is used which differs from the *linear_history* option by an additional factor of \( a \), the radius of the contact region. The tangential force is given by:

\[
\mathbf{F}_t = -\min(\mu_t F_{n0}, ||F_{te} + F_{t,damp}||) \mathbf{t}
\]

Here, \( a \) is the radius of the contact region, given by \( a = \sqrt{R\delta} \) for all normal contact models, except for *jkr*, where it is given implicitly by \( \delta = a^2/R - 2\sqrt{\pi\gamma a/E} \), see discussion above. To match the Mindlin solution, one should set \( k_t = 8G_{eff} \), where \( G_{eff} \) is the effective shear modulus given by:

\[
G_{eff} = \left( \frac{2 - \nu_i}{G_i} + \frac{2 - \nu_j}{G_j} \right)^{-1}
\]

where \( G \) is the shear modulus, related to Young’s modulus \( E \) and Poisson’s ratio \( \nu \) by \( G = E/(2(1+\nu)) \). This can also be achieved by specifying NULL for \( k_t \), in which case a normal contact model that specifies material parameters \( E \) and \( \nu \) is required (e.g. *hertz/material*, *dmt* or *jkr*). In this case, mixing of the shear modulus for different particle types \( i \) and \( j \) is done according to the formula above.

**Note:** The radius of the contact region \( a \) depends on the normal overlap. As a result, the tangential force for *mindlin* can change due to a variation in normal overlap, even with no change in tangential displacement.

For *tangential mindlin/force*, the accumulated elastic tangential force characterizes the contact history, instead of the accumulated tangential displacement. This prevents the dependence of the tangential force on the normal overlap as noted above. The tangential force is given by:

\[
\mathbf{F}_t = -\min(\mu_t F_{n0}, ||F_{te} + F_{t,damp}||) \mathbf{t}
\]

The increment of the elastic component of the tangential force \( F_{te} \) is given by:

\[
dF_{te} = -k_t a \mathbf{v}_{t,rel} d\tau
\]

The changes in frame of reference of the contacting pair of particles during contact are accounted for by the same formula as above, replacing the accumulated tangential displacement \( \xi \), by the accumulated tangential elastic force \( F_{te} \). When the tangential force exceeds the critical force, the tangential force is directly re-scaled to match the value for the critical force:

\[
F_{te} = -\mu_t F_{n0} \mathbf{t} + F_{t,damp}
\]

The same rules as those described for *mindlin* apply regarding the tangential stiffness and mixing of the shear modulus for different particle types.

The *mindlin_rescale* option uses the same form as *mindlin*, but the magnitude of the tangential displacement is re-scaled as the contact unloads, i.e. if \( a < a_{t_{n-1}} \):

\[
\xi = \xi_{t_{n-1}} \frac{a}{a_{t_{n-1}}}
\]

Here, \( t_{n-1} \) indicates the value at the previous time step. This rescaling accounts for the fact that a decrease in the contact area upon unloading leads to the contact being unable to support the previous tangential loading, and spurious energy is created without the rescaling above (Walton).

**Note:** For *mindlin*, a decrease in the tangential force already occurs as the contact unloads, due to the dependence of the tangential force on the normal force described above. By re-scaling \( \xi \), *mindlin_rescale* effectively re-scales the tangential force twice, i.e., proportionally to \( a^2 \). This peculiar behavior results from use of the accumulated tangential force.
displacement to characterize the contact history. Although mindlin_rescale remains available for historic reasons and backward compatibility purposes, it should be avoided in favor of mindlin_rescale/force.

The mindlin_rescale/force option uses the same form as mindlin/force, but the magnitude of the tangential elastic force is re-scaled as the contact unloads, i.e. if \( a < a_{t_{n-1}} \):

\[
F_{te} = F_{te,t_{n-1}} \frac{a}{a_{t_{n-1}}}
\]

This approach provides a better approximation of the Mindlin-Deresiewicz laws and is more consistent than mindlin_rescale. See discussions in Thornton et al, 2013, particularly equation 18(b) of that work and associated discussion, and Agnolin and Roux, 2007, particularly Appendix A.

The optional rolling keyword enables rolling friction, which resists pure rolling motion of particles. The options currently supported are:

1. none
2. sds: \( k_{roll}, \gamma_{roll}, \mu_{roll} \)

If the rolling keyword is not specified, the model defaults to none.

For rolling sds, rolling friction is computed via a spring-dashpot-slider, using a ‘pseudo-force’ formulation, as detailed by Luding. Unlike the formulation in Marshall, this allows for the required adjustment of rolling displacement due to changes in the frame of reference of the contacting pair. The rolling pseudo-force is computed analogously to the tangential force:

\[
F_{roll,0} = k_{roll} \xi_{roll} - \gamma_{roll} v_{roll}
\]

Here, \( v_{roll} = -R(\Omega_i - \Omega_j) \times n \) is the relative rolling velocity, as given in Wang et al and Luding. This differs from the expressions given by Kuhn and Bagi and used in Marshall; see Wang et al for details. The rolling displacement is given by:

\[
\xi_{roll} = \int_{t_0}^{t} v_{roll}(\tau) d\tau
\]

A Coulomb friction criterion truncates the rolling pseudo-force if it exceeds a critical value:

\[
F_{roll} = \min(\mu_{roll} F_{n,0}, \parallel F_{roll,0} \parallel) k
\]

Here, \( k = v_{roll}/\parallel v_{roll} \parallel \) is the direction of the pseudo-force. As with tangential displacement, the rolling displacement is rescaled when the critical force is exceeded, so that the spring length corresponds the critical force. Additionally, the displacement is adjusted to account for rotations of the frame of reference of the two contacting particles in a manner analogous to the tangential displacement.

The rolling pseudo-force does not contribute to the total force on either particle (hence ‘pseudo’), but acts only to induce an equal and opposite torque on each particle, according to:

\[
\tau_{roll,i} = R_{ef} n \times F_{roll}
\]

\[
\tau_{roll,j} = -\tau_{roll,i}
\]

The optional twisting keyword enables twisting friction, which resists rotation of two contacting particles about the vector \( n \) that connects their centers. The options currently supported are:
If the `twisting` keyword is not specified, the model defaults to `none`.

For both `twisting sds` and `twisting marshall`, a history-dependent spring-dashpot-slider is used to compute the twisting torque. Because twisting displacement is a scalar, there is no need to adjust for changes in the frame of reference due to rotations of the particle pair. The formulation in *Marshall* therefore provides the most straightforward treatment:

\[
\tau_{\text{twist},0} = -k_{\text{twist}} \xi_{\text{twist}} - \gamma_{\text{twist}} \Omega_{\text{twist}}
\]

Here \( \xi_{\text{twist}} = \int_{t_0}^{t} \Omega_{\text{twist}}(\tau)d\tau \) is the twisting angular displacement, and \( \Omega_{\text{twist}} = (\Omega_i - \Omega_j) \cdot n \) is the relative twisting angular velocity. The torque is then truncated according to:

\[
\tau_{\text{twist}} = \min(\mu_{\text{twist}} F_{n,0}, \tau_{\text{twist},0})
\]

Similar to the sliding and rolling displacement, the angular displacement is rescaled so that it corresponds to the critical value if the twisting torque exceeds this critical value:

\[
\xi_{\text{twist}} = \frac{1}{k_{\text{twist}}} (\mu_{\text{twist}} F_{n,0} sgn(\Omega_{\text{twist}}) - \gamma_{\text{twist}} \Omega_{\text{twist}})
\]

For `twisting sds`, the coefficients \( k_{\text{twist}}, \gamma_{\text{twist}} \) and \( \mu_{\text{twist}} \) are simply the user input parameters that follow the `twisting sds` keywords in the `pair_coeff` command.

For `twisting marshall`, the coefficients are expressed in terms of sliding friction coefficients, as discussed in *Marshall* (see equations 32 and 33 of that work):

\[
k_{\text{twist}} = 0.5 k_{i} a^{2}
\]

\[
\eta_{\text{twist}} = 0.5 \eta_{i} a^{2}
\]

\[
\mu_{\text{twist}} = \frac{2}{3} a \mu_{i}
\]

Finally, the twisting torque on each particle is given by:

\[
\tau_{\text{twist},i} = \tau_{\text{twist}} n
\]

\[
\tau_{\text{twist},j} = -\tau_{\text{twist},i}
\]

The **granular** pair style can reproduce the behavior of the **pair gran/*** styles with the appropriate settings (some very minor differences can be expected due to corrections in displacement history frame-of-reference, and the application of the torque at the center of the contact rather than at each particle). The first example above is equivalent to `pair gran/hooke 1000.0 NULL 50.0 50.0 0.4 1`. The second example is equivalent to `pair gran/hooke/history 1000.0 500.0 50.0 50.0 0.4 1`. The third example is equivalent to `pair gran/hertz/history 1000.0 500.0 50.0 50.0 0.4 1`.

LAMMPS automatically sets pairwise cutoff values for **pair_style granular** based on particle radii (and in the case of **jkr** pull-off distances). In the vast majority of situations, this is adequate. However, a cutoff value can optionally be appended to the **pair_style granular** command to specify a global cutoff (i.e. a cutoff for all atom types). Additionally, the optional `cutoff` keyword can be passed to the **pair_coeff** command, followed by a cutoff value. This will set a pairwise cutoff for the atom types in the **pair_coeff** command. These options may be useful in some rare cases where the automatic cutoff determination is not sufficient, e.g. if particle diameters are being modified via the `fix`
adapt command. In that case, the global cutoff specified as part of the pair_style granular command is applied to all atom types, unless it is overridden for a given atom type combination by the cutoff value specified in the pair coeff command. If cutoff is only specified in the pair coeff command and no global cutoff is appended to the pair_style granular command, then LAMMPS will use that cutoff for the specified atom type combination, and automatically set pairwise cutoffs for the remaining atom types.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.102.4 Mixing, shift, table, tail correction, restart, rRESPA info

The pair_modify mix, shift, table, and tail options are not relevant for granular pair styles.

Mixing of coefficients is carried out using geometric averaging for most quantities, e.g. if friction coefficient for type 1-type 1 interactions is set to \( \mu_1 \), and friction coefficient for type 2-type 2 interactions is set to \( \mu_2 \), the friction coefficient for type1-type2 interactions is computed as \( \sqrt{\mu_1 \mu_2} \) (unless explicitly specified to a different value by a pair_coeff I J ... command). The exception to this is elastic modulus, only applicable to hertz/material, dmt and jkr normal contact models. In that case, the effective elastic modulus is computed as:

\[
E_{\text{eff},ij} = \left( \frac{1 - \nu_i^2}{E_i} + \frac{1 - \nu_j^2}{E_j} \right)^{-1}
\]

If the i-j coefficients \( E_{ij} \) and \( \nu_{ij} \) are explicitly specified, the effective modulus is computed as:

\[
E_{\text{eff},ij} = \left( \frac{1 - \nu_{ij}^2}{E_{ij}} + \frac{1 - \nu_{ij}^2}{E_{ij}} \right)^{-1}
\]

or

\[
E_{\text{eff},ij} = \frac{E_{ij}}{2(1 - \nu_{ij})}
\]

These pair styles write their information to binary restart files, so a pair_style command does not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

The single() function of these pair styles returns 0.0 for the energy of a pairwise interaction, since energy is not conserved in these dissipative potentials. It also returns only the normal component of the pairwise interaction force. However, the single() function also calculates 12 extra pairwise quantities. The first 3 are the components of the tangential force between particles I and J, acting on particle I. The fourth is the magnitude of this tangential force. The next 3 (5-7) are the components of the rolling torque acting on particle I. The next entry (8) is the magnitude of the rolling torque. The next entry (9) is the magnitude of the twisting torque acting about the vector connecting the two
particle centers. The last 3 (10-12) are the components of the vector connecting the centers of the two particles \((x_I - x_J)\).

These extra quantities can be accessed by the \texttt{compute pair/local} command, as \(p1, p2, \ldots, p12\).

\section*{20.102.5 Restrictions}
All the granular pair styles are part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the \texttt{Build package} doc page for more info.

These pair styles require that atoms store torque and angular velocity (omega) as defined by the \texttt{atom_style}. They also require a per-particle radius is stored. The \texttt{sphere} atom style does all of this.

This pair style requires you to use the \texttt{comm_modify vel yes} command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the \texttt{read_restart} command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the \texttt{read_restart} command for more details.

pair_coeff * * 100.0 2.0
pair_coeff 2 2 100.0 2.0 8.0 10.0

pair_style lj/gromacs/coul/gromacs 9.0 12.0
pair_style lj/gromacs/coul/gromacs 8.0 10.0 7.0 9.0
pair_coeff * * 100.0 2.0
```
20.104.3 Description

The \textit{lj/gromacs} styles compute shifted LJ and Coulombic interactions with an additional switching function \( S(r) \) that ramps the energy and force smoothly to zero between an inner and outer cutoff. It is a commonly used potential in the GROMACS MD code and for the coarse-grained models of (Marrink).

\[
E_{LJ} = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] + S_{LJ}(r) \quad r < r_c
\]

\[
E_C = \frac{C_q i q_j}{\epsilon r} + S_C(r) \quad r < r_c
\]

\[S(r) = C \quad r < r_1\]

\[S(r) = \frac{A}{3} (r - r_1)^3 + \frac{B}{4} (r - r_1)^4 + C \quad r_1 < r < r_c\]

\[A = (-3E'(r_c) + (r_c - r_1)E''(r_c))/(r_c - r_1)^2\]

\[B = (2E'(r_c) - (r_c - r_1)E''(r_c))/(r_c - r_1)^3\]

\[C = -E(r_c) + \frac{1}{2} (r_c - r_1)E'(r_c) - \frac{1}{12} (r_c - r_1)^2 E''(r_c)\]

\( r_1 \) is the inner cutoff; \( r_c \) is the outer cutoff. The coefficients \( A, B, \) and \( C \) are computed by LAMMPS to perform the shifting and smoothing. The function \( S(r) \) is actually applied once to each term of the LJ formula and once to the Coulombic formula, so there are 2 or 3 sets of \( A, B, C \) coefficients depending on which pair_style is used. The boundary conditions applied to the smoothing function are as follows: \( S'(r_1) = S''(r_1) = 0, S(r_c) = -E(r_c), S'(r_c) = -E'(r_c), \) and \( S''(r_c) = -E''(r_c) \), where \( E(r) \) is the corresponding term in the LJ or Coulombic potential energy function. Single and double primes denote first and second derivatives with respect to \( r \), respectively.

The inner and outer cutoff for the LJ and Coulombic terms can be the same or different depending on whether 2 or 4 arguments are used in the pair_style command. The inner LJ cutoff must be > 0, but the inner Coulombic cutoff can be >= 0.

The following coefficients must be defined for each pair of atoms types via the \texttt{pair_coeff} command as in the examples above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- inner (distance units)
- outer (distance units)

Note that sigma is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at \( 2^{1/6}\sigma \).

The last 2 coefficients are optional inner and outer cutoffs for style \textit{lj/gromacs}. If not specified, the global \textit{inner} and \textit{outer} values are used.

The last 2 coefficients cannot be used with style \textit{lj/gromacs/coul/gromacs} because this force field does not allow varying cutoffs for individual atom pairs; all pairs use the global cutoff(s) specified in the pair_style command.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} doc page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.104.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

None of the GROMACS pair styles support the pair_modify shift option, since the Lennard-Jones portion of the pair interaction is already smoothed to 0.0 at the cutoff.

The pair_modify table option is not relevant for this pair style.

None of the GROMACS pair styles support the pair_modify tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

All of the GROMACS pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

All of the GROMACS pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

### 20.104.5 Restrictions

none

### 20.104.6 Related commands

pair_coeff

### 20.104.7 Default

none

### 20.105 pair_style gw command

### 20.106 pair_style gw/zbl command

#### 20.106.1 Syntax

```
pair_style style
```

- style = gw or gw/zbl
20.106.2 Examples

```
pair_style gw
pair_coeff * * SiC.gw Si C C

pair_style gw/zbl
pair_coeff * * SiC.gw.zbl C Si
```

20.106.3 Description

The `gw` style computes a 3-body *Gao-Weber* potential; similarly `gw/zbl` combines this potential with a modified repulsive ZBL core function in a similar fashion as implemented in the `tersoff/zbl` pair style.

Unfortunately the author of this contributed code has not been able to submit a suitable documentation explaining the details of the potentials. The LAMMPS developers thus have finally decided to release the code anyway with only the technical explanations. For details of the model and the parameters, please refer to the linked publication.

Only a single `pair_coeff` command is used with the `gw` and `gw/zbl` styles which specifies a Gao-Weber potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of GW elements to atom types

See the `pair_coeff` doc page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.gw has Gao-Weber values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following `pair_coeff` command:

```
pair_coeff * * SiC.gw Si Si Si C
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1, 2, 3 to the Si element in the GW file. The final C argument maps LAMMPS atom type 4 to the C element in the GW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a `gw` potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Gao-Weber files in the `potentials` directory of the LAMMPS distribution have a “.gw” suffix. Gao-Weber with ZBL files have a “.gz.zbl” suffix. The structure of the potential files is similar to other many-body potentials supported by LAMMPS. You have to refer to the comments in the files and the literature to learn more details.

20.106.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.
20.106.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The Gao-Weber potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the GW potential with any LAMMPS units, but you would need to create your own GW potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

```

20.108.3 Description

The `hbond/dreiding` styles compute the Acceptor-Hydrogen-Donor (AHD) 3-body hydrogen bond interaction for the DREIDING force field, given by:

\[
E = \begin{cases} 
  S(r) \times [LJ(r)|Morse(r)] & r < r_{\text{in}} \\
  0 & r_{\text{in}} < r < r_{\text{out}} \\
  -BR^{-10} \cos^n \theta & r > r_{\text{out}} 
\end{cases}
\]

where

\[
LJ(r) = AR^{-12} - BR^{-10} \cos^n \theta = \epsilon \left\{ 5 \left( \frac{\sigma}{r} \right)^{12} - 6 \left( \frac{\sigma}{r} \right)^{10} \right\} \cos^n \theta
\]

\[
Morse(r) = D_0 \left\{ \chi^2 - 2 \chi \right\} \cos^n \theta = D_0 \left\{ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right\} \cos^n \theta
\]

\[
S(r) = \frac{r_{\text{out}}^2 - r^2}{r_{\text{out}}^2 - r^2} \times \frac{[r_{\text{out}}^2 + 2r^2 - 3r_{\text{in}}^2]}{[r_{\text{out}}^2 - r_{\text{in}}^2]^3}
\]

where \( r_{\text{in}} \) is the inner spline distance cutoff, \( r_{\text{out}} \) is the outer distance cutoff, \( \theta_c \) is the angle cutoff, and \( n \) is the cosine periodicity.

Here, \( r \) is the radial distance between the donor (D) and acceptor (A) atoms and \( \theta \) is the bond angle between the acceptor, the hydrogen (H) and the donor atoms:

These 3-body interactions can be defined for pairs of acceptor and donor atoms, based on atom types. For each donor/acceptor atom pair, the third atom in the interaction is a hydrogen permanently bonded to the donor atom, e.g. in a bond list read in from a data file via the `read_data` command. The atom types of possible hydrogen atoms for each donor/acceptor type pair are specified by the `pair_coeff` command (see below).
Style \texttt{hbond/dreiding/lj} is the original DREIDING potential of \cite{Mayo}. It uses a LJ 12/10 functional for the Donor-Acceptor interactions. To match the results in the original paper, use \( n = 4 \).

Style \texttt{hbond/dreiding/morse} is an improved version using a Morse potential for the Donor-Acceptor interactions. \cite{Liu} showed that the Morse form gives improved results for Dendrimer simulations, when \( n = 2 \).

See the \texttt{Howto bioFF} doc page for more information on the DREIDING force field.

\textbf{Note:} Because the Dreiding hydrogen bond potential is only one portion of an overall force field which typically includes other pairwise interactions, it is common to use it as a sub-style in a \texttt{pair_style hybrid/overlay} command, where another pair style provides the repulsive core interaction between pairs of atoms, e.g. a \( 1/r^12 \) Lennard-Jones repulsion.

\textbf{Note:} When using the \texttt{hbond/dreiding} pair styles with \texttt{pair_style hybrid/overlay}, you should explicitly define pair interactions between the donor atom and acceptor atoms, (as well as between these atoms and ALL other atoms in your system). Whenever \texttt{pair_style hybrid/overlay} is used, ordinary mixing rules are not applied to atoms like the donor and acceptor atoms because they are typically referenced in multiple pair styles. Neglecting to do this can cause difficult-to-detect physics problems.

\textbf{Note:} In the original Dreiding force field paper 1-4 non-bonded interactions \textbf{ARE} allowed. If this is desired for your model, use the \texttt{special_bonds} command (e.g. \texttt{”special_bonds lj 0.0 0.0 1.0”}) to turn these interactions on.

The following coefficients must be defined for pairs of eligible donor/acceptor types via the \texttt{pair_coeff} command as in the examples above.

\textbf{Note:} Unlike other pair styles and their associated \texttt{pair_coeff} commands, you do not need to specify \texttt{pair_coeff} settings for all possible IJ type pairs. Only IJ type pairs for atoms which act as joint donors/acceptors need to be specified; all other type pairs are assumed to be inactive.

\textbf{Note:} A \texttt{pair_coeff} command can be specified multiple times for the same donor/acceptor type pair. This enables multiple hydrogen types to be assigned to the same donor/acceptor type pair. For other pair styles, if the \texttt{pair_coeff} command is re-used for the same IJ type pair, the settings for that type pair are overwritten. For the hydrogen bond potentials this is not the case; the settings are cumulative. This means the only way to turn off a previous setting, is to re-use the \texttt{pair_style} command and start over.

For the \texttt{hbond/dreiding/lj} style the list of coefficients is as follows:

- \( K = \) hydrogen atom type = 1 to Ntypes
- \( \text{donor flag} = i \) or \( j \)
- \( \epsilon = \) (energy units)
- \( \sigma = \) (distance units)
- \( n = \) exponent in formula above
- \( \text{distance cutoff} \ r_{\text{in}} = \) (distance units)
- \( \text{distance cutoff} \ r_{\text{out}} = \) (distance units)
For the `hbond/dreiding/morse` style the list of coefficients is as follows:

- K = hydrogen atom type = 1 to Ntypes
- donor flag = i or j
- $D_0$ (energy units)
- $\alpha$ (1/distance units)
- $r_0$ (distance units)
- $n$ = exponent in formula above
- distance cutoff $r_{in}$ (distance units)
- distance cutoff $r_{out}$ (distance units)
- angle cutoff (degrees)

A single hydrogen atom type K can be specified, or a wild-card asterisk can be used in place of or in conjunction with the K arguments to select multiple types as hydrogen atoms. This takes the form “*” or “#*” or “n#” or “m#n”. See the `pair_coeff` command doc page for details.

If the donor flag is $i$, then the atom of type I in the `pair_coeff` command is treated as the donor, and J is the acceptor. If the donor flag is $j$, then the atom of type J in the `pair_coeff` command is treated as the donor and I is the donor. This option is required because the `pair_coeff` command requires that $I \leq J$.

$\epsilon$ and $\sigma$ are settings for the hydrogen bond potential based on a Lennard-Jones functional form. Note that sigma is defined as the zero-crossing distance for the potential, not as the energy minimum at $2^{1/6}\sigma$.

$D_0$ and $\alpha$ and $r_0$ are settings for the hydrogen bond potential based on a Morse functional form.

The last 3 coefficients for both styles are optional. If not specified, the global $n$, distance cutoff, and angle cutoff specified in the `pair_style` command are used. If you wish to only override the second or third optional parameter, you must also specify the preceding optional parameters.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
20.108.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. You must explicitly identify each donor/acceptor type pair.

These styles do not support the `pair_modify` shift option for the energy of the interactions.

The `pair_modify` table option is not relevant for these pair styles.

These pair styles do not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

These pair styles do not write their information to binary restart files, so pair_style and pair_coeff commands need to be re-specified in an input script that reads a restart file.

These pair styles can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.

These pair styles tally a count of how many hydrogen bonding interactions they calculate each timestep and the hbond energy. These quantities can be accessed via the `compute pair` command as a vector of values of length 2.

To print these quantities to the log file (with a descriptive column heading) the following commands could be included in an input script:

```plaintext
compute hb all pair hbond/dreiding/lj
variable n_hbond equal c_hb[1] #number hbonds
variable E_hbond equal c_hb[2] #hbond energy
thermo_style custom step temp epair v_E_hbond
```

```

20.110.3 Description

The hybrid and hybrid/overlay styles enable the use of multiple pair styles in one simulation. With the hybrid style, exactly one pair style is assigned to each pair of atom types. With the hybrid/overlay style, one or more pair styles can be assigned to each pair of atom types. The assignment of pair styles to type pairs is made via the pair_coeff command.

Here are two examples of hybrid simulations. The hybrid style could be used for a simulation of a metal droplet on a LJ surface. The metal atoms interact with each other via an eam potential, the surface atoms interact with each other via a lj/cut potential, and the metal/surface interaction is also computed via a lj/cut potential. The hybrid/overlay style could be used as in the second example above, where multiple potentials are superposed in an additive fashion to compute the interaction between atoms. In this example, using lj/cut and coul/long together gives the same result as if the lj/cut/coul/long potential were used by itself. In this case, it would be more efficient to use the single combined potential, but in general any combination of pair potentials can be used together in to produce an interaction that is not encoded in any single pair_style file, e.g. adding Coulombic forces between granular particles.

All pair styles that will be used are listed as “sub-styles” following the hybrid or hybrid/overlay keyword, in any order. Each sub-style’s name is followed by its usual arguments, as illustrated in the example above. See the doc pages of individual pair styles for a listing and explanation of the appropriate arguments.

Note that an individual pair style can be used multiple times as a sub-style. For efficiency this should only be done if your model requires it. E.g. if you have different regions of Si and C atoms and wish to use a Tersoff potential for pure Si for one set of atoms, and a Tersoff potential for pure C for the other set (presumably with some third potential for Si-C interactions), then the sub-style tersoff could be listed twice. But if you just want to use a Lennard-Jones or
other pairwise potential for several different atom type pairs in your model, then you should just list the sub-style once
and use the pair_coeff command to assign parameters for the different type pairs.

**Note:** There is one exception to this option to list an individual pair style multiple times: GPU-enabled pair styles in
the GPU package. This is because the GPU package currently assumes that only one instance of a pair style is being
used.

In the pair_coeff commands, the name of a pair style must be added after the I,J type specification, with the remaining
coefficients being those appropriate to that style. If the pair style is used multiple times in the pair_style command,
then an additional numeric argument must also be specified which is a number from 1 to M where M is the number of
times the sub-style was listed in the pair style command. The extra number indicates which instance of the sub-style
coefficients apply to.

For example, consider a simulation with 3 atom types: types 1 and 2 are Ni atoms, type 3 are LJ atoms with charges.
The following commands would set up a hybrid simulation:

```plaintext
pair_style hybrid eam/alloy lj/cut/coul/cut 10.0 lj/cut 8.0
pair_coeff * * eam/alloy nialhjea Ni Ni NULL
pair_coeff 3 3 lj/cut/coul/cut 1.0 1.0
pair_coeff 1*2 3 lj/cut 0.8 1.3
```

As an example of using the same pair style multiple times, consider a simulation with 2 atom types. Type 1 is Si,
type 2 is C. The following commands would model the Si atoms with Tersoff, the C atoms with Tersoff, and the
cross-interactions with Lennard-Jones:

```plaintext
pair_style hybrid lj/cut 2.5 tersoff tersoff
pair_coeff * * tersoff 1 Si.tersoff Si NULL
pair_coeff * * tersoff 2 C.tersoff NULL C
pair_coeff 1 2 lj/cut 1.0 1.5
```

If pair coefficients are specified in the data file read via the `read_data` command, then the same rule applies. E.g.
“eam/alloy” or “lj/cut” must be added after the atom type, for each line in the “Pair Coeffs” section, e.g.

```plaintext
Pair Coeffs
1 lj/cut/coul/cut 1.0 1.0
...
```

Note that the pair_coeff command for some potentials such as `pair_style eam/alloy` includes a mapping specification
of elements to all atom types, which in the hybrid case, can include atom types not assigned to the `eam/alloy` potential.
The NULL keyword is used by many such potentials (eam/alloy, Tersoff, AIREBO, etc), to denote an atom type that
will be assigned to a different sub-style.

For the `hybrid` style, each atom type pair I,J is assigned to exactly one sub-style. Just as with a simulation using a
single pair style, if you specify the same atom type pair in a second pair_coeff command, the previous assignment will
be overwritten.

For the `hybrid/overlay` style, each atom type pair I,J can be assigned to one or more sub-styles. If you specify the same
atom type pair in a second pair_coeff command with a new sub-style, then the second sub-style is added to the list of
potentials that will be calculated for two interacting atoms of those types. If you specify the same atom type pair in
a second pair_coeff command with a sub-style that has already been defined for that pair of atoms, then the new pair
coefficients simply override the previous ones, as in the normal usage of the pair_coeff command. E.g. these two sets
of commands are the same:

```plaintext
pair_style lj/cut 2.5
pair_coeff * * 1.0 1.0
```
Coefficients must be defined for each pair of atoms types via the `pair_coeff` command as described above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below.

For both the `hybrid` and `hybrid/overlay` styles, every atom type pair \( I,J \) (where \( I \leq J \)) must be assigned to at least one sub-style via the `pair_coeff` command as in the examples above, or in the data file read by the `read_data`, or by mixing as described below.

If you want there to be no interactions between a particular pair of atom types, you have 3 choices. You can assign the type pair to some sub-style and use the `neigh_modify exclude type` command. You can assign it to some sub-style and set the coefficients so that there is effectively no interaction (e.g. \( \epsilon = 0.0 \) in a LJ potential). Or, for `hybrid` and `hybrid/overlay` simulations, you can use this form of the `pair_coeff` command in your input script:

```
pair_coeff 2 3 none
```

or this form in the “Pair Coeffs” section of the data file:

```
3 none
```

If an assignment to `none` is made in a simulation with the `hybrid/overlay` pair style, it wipes out all previous assignments of that atom type pair to sub-styles.

Note that you may need to use an `atom_style` hybrid command in your input script, if atoms in the simulation will need attributes from several atom styles, due to using multiple pair potentials.

Different force fields (e.g. CHARMM vs AMBER) may have different rules for applying weightings that change the strength of pairwise interactions between pairs of atoms that are also 1-2, 1-3, and 1-4 neighbors in the molecular bond topology, as normally set by the `special_bonds` command. Different weights can be assigned to different pair hybrid sub-styles via the `pair_modify special` command. This allows multiple force fields to be used in a model of a hybrid system, however, there is no consistent approach to determine parameters automatically for the interactions between the two force fields, this is only recommended when particles described by the different force fields do not mix.

Here is an example for mixing CHARMM and AMBER: The global `amber` setting sets the 1-4 interactions to non-zero scaling factors and then overrides them with 0.0 only for CHARMM:

```
special_bonds amber
pair_hybrid lj/charmm/coul/long 8.0 10.0 lj/cut/coul/long 10.0
pair_modify pair lj/charmm/coul/long special lj/coul 0.0 0.0 0.0
```

The this input achieves the same effect:

```
special_bonds 0.0 0.0 0.1
pair_hybrid lj/charmm/coul/long 8.0 10.0 lj/cut/coul/long 10.0
pair_modify pair lj/coul/long special lj 0.0 0.0 0.5
pair_modify pair lj/coul/long special coul 0.0 0.0 0.83333333
pair_modify pair lj/charmm/coul/long special lj/coul 0.0 0.0 0.0
```

Here is an example for mixing Tersoff with OPLS/AA based on a data file that defines bonds for all atoms where for the Tersoff part of the system the force constants for the bonded interactions have been set to 0. Note the global settings are effectively `lj/coul 0.0 0.0 0.5` as required for OPLS/AA:

```
20.110. `pair_style hybrid/overlay command` 1839
```
special_bonds lj/coul 1e-20 1e-20 0.5  
pair_hybrid tersoff lj/cut/coul/long 12.0  
pair_modify pair tersoff special lj/coul 1.0 1.0 1.0

For use with the various compute *tally computes, the pair_modify compute/tally command can be used to selectively turn off processing of the compute tally styles, for example, if those pair styles (e.g. many-body styles) do not support this feature.

See the pair_modify doc page for details on the specific syntax, requirements and restrictions.

The potential energy contribution to the overall system due to an individual sub-style can be accessed and output via the compute pair command.

---

**Note:** Several of the potentials defined via the pair_style command in LAMMPS are really many-body potentials, such as Tersoff, AIREBO, MEAM, ReaxFF, etc. The way to think about using these potentials in a hybrid setting is as follows.

A subset of atom types is assigned to the many-body potential with a single pair_coeff command, using “* *” to include all types and the NULL keywords described above to exclude specific types not assigned to that potential. If types 1,3,4 were assigned in that way (but not type 2), this means that all many-body interactions between all atoms of types 1,3,4 will be computed by that potential. Pair_style hybrid allows interactions between type pairs 2-2, 1-2, 2-3, 2-4 to be specified for computation by other pair styles. You could even add a second interaction for 1-1 to be computed by another pair style, assuming pair_style hybrid/overlay is used.

But you should not, as a general rule, attempt to exclude the many-body interactions for some subset of the type pairs within the set of 1,3,4 interactions, e.g. exclude 1-1 or 1-3 interactions. That is not conceptually well-defined for many-body interactions, since the potential will typically calculate energies and forces for small groups of atoms, e.g. 3 or 4 atoms, using the neighbor lists of the atoms to find the additional atoms in the group. It is typically non-physical to think of excluding an interaction between a particular pair of atoms when the potential computes 3-body or 4-body interactions.

However, you can still use the pair_coeff none setting or the neigh_modify exclude command to exclude certain type pairs from the neighbor list that will be passed to a many-body sub-style. This will alter the calculations made by a many-body potential, since it builds its list of 3-body, 4-body, etc interactions from the pair list. You will need to think carefully as to whether it produces a physically meaningful result for your model.

For example, imagine you have two atom types in your model, type 1 for atoms in one surface, and type 2 for atoms in the other, and you wish to use a Tersoff potential to compute interactions within each surface, but not between surfaces. Then either of these two command sequences would implement that model:

```
pair_style hybrid tersoff
pair_coeff * * tersoff SiC.tersoff C C
pair_coeff 1 2 none
```

Either way, only neighbor lists with 1-1 or 2-2 interactions would be passed to the Tersoff potential, which means it would compute no 3-body interactions containing both type 1 and 2 atoms.

Here is another example, using hybrid/overlay, to use 2 many-body potentials together, in an overlapping manner. Imagine you have CNT (C atoms) on a Si surface. You want to use Tersoff for Si/Si and Si/C interactions, and AIREBO for C/C interactions. Si atoms are type 1; C atoms are type 2. Something like this will work:

```
pair_style hybrid tersoff
pair_coeff * * tersoff SiC.tersoff C C
pair_coeff 1 2 none
pair_style tersoff
pair_coeff * * SiC.tersoff C C
neigh_modify exclude type 1 2
```
pair_style hybrid/overlay tersoff airebo 3.0
pair_coeff * * tersoff SiC.tersoff.custom Si C
pair_coeff * * airebo CH.airebo NULL C

Note that to prevent the Tersoff potential from computing C/C interactions, you would need to modify the SiC.tersoff file to turn off C/C interaction, i.e. by setting the appropriate coefficients to 0.0.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page.

Since the hybrid and hybrid/overlay styles delegate computation to the individual sub-styles, the suffix versions of the hybrid and hybrid/overlay styles are used to propagate the corresponding suffix to all sub-styles, if those versions exist. Otherwise the non-accelerated version will be used.

The individual accelerated sub-styles are part of the GPU, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.110.4 Mixing, shift, table, tail correction, restart, rRESPA info

Any pair potential settings made via the pair_modify command are passed along to all sub-styles of the hybrid potential.

For atom type pairs I,J and I != J, if the sub-style assigned to I,I and J,J is the same, and if the sub-style allows for mixing, then the coefficients for I,J can be mixed. This means you do not have to specify a pair_coeff command for I,J since the I,J type pair will be assigned automatically to the sub-style defined for both I,I and J,J and its coefficients generated by the mixing rule used by that sub-style. For the hybrid/overlay style, there is an additional requirement that both the I,I and J,J pairs are assigned to a single sub-style. See the “pair_modify” command for details of mixing rules. See the See the doc page for the sub-style to see if allows for mixing.

The hybrid pair styles supports the pair_modify shift, table, and tail options for an I,J pair interaction, if the associated sub-style supports it.

For the hybrid pair styles, the list of sub-styles and their respective settings are written to binary restart files, so a pair_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file. Thus, pair_coeff commands need to be re-specified in the restart input script.

These pair styles support the use of the inner, middle, and outer keywords of the run_style respa command, if their sub-styles do.
20.110.5 Restrictions

When using a long-range Coulombic solver (via the \textit{k}sp\textit{a}ce\_\textit{st}yle\ command) with a hybrid pair\_style, one or more sub-styles will be of the “long” variety, e.g. \texttt{lj/cut/coul/long} or \texttt{buck/coul/long}. You must insure that the short-range Coulombic cutoff used by each of these long pair styles is the same or else LAMMPS will generate an error.

pair\_coeff 1 1 coul/shield 0.70
pair\_coeff 1 2 coul/shield 0.695
pair\_coeff 2 2 coul/shield 0.69
\end{verbatim}
20.111.3 Description

The *ilp/graphene/hbn* style computes the registry-dependent interlayer potential (ILP) potential as described in (Leven1), (Leven2) and (Maaravi). The normals are calculated in the way as described in (Kolmogorov).

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} \sum_{\beta} V_{ij} \rho_{ij}^2 \rho_{ji}^2 \left\{ e^{-(\rho_{ij}/\beta - 1)} \left[ C_6 \left( \frac{\rho_{ij}}{\rho_{ij}^2} \right)^{6} + 84 \left( \frac{\rho_{ij}}{\rho_{ij}^2} \right)^{5} - 35 \left( \frac{\rho_{ij}}{\rho_{ij}^2} \right)^{4} + 1 \right] \right\}
\]

Where Tap(r_{ij}) is the taper function which provides a continuous cutoff (up to third derivative) for interatomic separations larger than r_c (Maaravi). The definitions of each parameter in the above equation can be found in (Leven1) and (Maaravi).

It is important to include all the pairs to build the neighbor list for calculating the normals.

**Note:** This potential (ILP) is intended for interlayer interactions between two different layers of graphene, hexagonal boron nitride (h-BN) and their hetero-junction. To perform a realistic simulation, this potential must be used in combination with intralayer potential, such as AIREBO or Tersoff potential. To keep the intralayer properties unaffected, the interlayer interaction within the same layers should be avoided. Hence, each atom has to have a layer identifier such that atoms residing on the same layer interact via the appropriate intralayer potential and atoms residing on different layers interact via the ILP. Here, the molecule id is chosen as the layer identifier, thus a data file with the “full” atom style is required to use this potential.

The parameter file (e.g. BNCH.ILP), is intended for use with metal units, with energies in meV. Two additional parameters, \( S \), and \( r_{cut} \) are included in the parameter file. \( S \) is designed to facilitate scaling of energies. \( r_{cut} \) is designed to build the neighbor list for calculating the normals for each atom pair.

**Note:** The parameters presented in the parameter file (e.g. BNCH.ILP), are fitted with taper function by setting the cutoff equal to 16.0 Angstrom. Using different cutoff or taper function should be careful. The parameters for atoms pairs between Boron and Nitrogen are fitted with a screened Coulomb interaction coul/shield. Therefore, to simulated the properties of h-BN correctly, this potential must be used in combination with the pair style coul/shield.

**Note:** Four new sets of parameters of ILP for 2D layered Materials with bilayer and bulk configurations are presented in (Ouyang1) and (Ouyang2), respectively. These parameters provide a good description in both short- and long-range interaction regimes. While the old ILP parameters published in (Leven2) and (Maaravi) are only suitable for long-range interaction regime. This feature is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance). The benchmark tests and comparison of these parameters can be found in (Ouyang1) and (Ouyang2).

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style none.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the compute pair command as a vector of values of length 2. The 2 values correspond to the following sub-categories:
1. \( E_{\text{vdW}} = \text{vdW (attractive) energy} \)

2. \( E_{\text{Rep}} = \text{Repulsive energy} \)

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```plaintext
compute 0 all pair ilp/graphene/hbn
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

### 20.111.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

### 20.111.5 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair potential requires the newton setting to be on for pair interactions.

The BNCH.ILP potential file provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use this potential with any LAMMPS units, but you would need to create your BNCH.ILP potential file with coefficients listed in the appropriate units, if your simulation does not use metal units.

### 20.111.6 Related commands

`pair_coeff`, `pair_none`, `pair_style hybrid/overlay`, `pair_style dip`, `pair_style pair_kolmogorov_crespi_z`, `pair_style pair_kolmogorov_crespi_full`, `pair_style pair_lebedeva_z`, `pair_style pair_coul_shield`.

### 20.111.7 Default

`tap_flag = 1`

---

20.112 pair_style kim command

20.112.1 Syntax

```plaintext
pair_style kim model
```

model = name of a KIM model (the KIM ID for models archived in OpenKIM)

20.112.2 Examples

```plaintext
pair_style kim SW_ScillingerWeber_1985_Si__MO_405120566662_005
pair_coeff * * Si
```

20.112.3 Description

This pair style is a wrapper on the Open Knowledgebase of Interatomic Models (OpenKIM) repository of interatomic potentials to enable their use in LAMMPS scripts.

The preferred interface for using interatomic models archived in OpenKIM is the `kim_commands interface`. That interface supports both “KIM Portable Models” (PMs) that conform to the KIM API Portable Model Interface (PMI) and can be used by any simulation code that conforms to the KIM API/PMI, and “KIM Simulator Models” that are natively implemented within a single simulation code (like LAMMPS) and can only be used with it. The `pair_style kim` command is limited to KIM PMs. It is used by the `kim_commands interface` as needed.

Note: Since `pair_style kim` is called by `kim_interactions` as needed, is not recommended to be directly used in input scripts.

The argument `model` is the name of the KIM PM. For potentials archived in OpenKIM this is the extended KIM ID (see `kim_commands` for details). LAMMPS can invoke any KIM PM, however there can be incompatibilities (for example due to unit matching issues). In the event of an incompatibility, the code will terminate with an error message. Check both the LAMMPS and KIM log files for details.

Only a single `pair_coeff` command is used with the `kim` style, which specifies the mapping of LAMMPS atom types to the species supported by the KIM PM. This is done by specifying `N` additional arguments after the `* *` in the `pair_coeff` command, where `N` is the number of LAMMPS atom types:

- `N` element names = mapping of KIM elements to atom types

For example, consider a KIM PM that supports Si and C species. If the LAMMPS simulation has four atom types, where the first three are Si, and the fourth is C, the following `pair_coeff` command would be used:

```plaintext
pair_coeff * * Si Si Si C
```

The first two arguments must be `* *` so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1, 2, and 3 to Si as defined within KIM PM. The final C argument maps LAMMPS atom type 4 to C.

In addition to the usual LAMMPS error messages, the KIM library itself may generate errors, which should be printed to the screen. In this case it is also useful to check the `kim.log` file for additional error information. The file `kim.log` should be generated in the same directory where LAMMPS is running.
LAMMPS Documentation

To download, build, and install the KIM library on your system, see the lib/kim/README file. Once you have done this and built LAMMPS with the KIM package installed you can run the example input scripts in examples/kim.

20.112.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since KIM stores the potential parameters. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.112.5 Restrictions

This pair style is part of the KIM package. See details on restrictions in kim_commands.

This current version of pair_style kim is compatible with the kim-api package version 2.0.0 and higher.

20.113.3 Description

The \textit{kolmogorov/crespi/full} style computes the Kolmogorov-Crespi (KC) interaction potential as described in \cite{Kolmogorov}. No simplification is made,

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}
\]

\[
V_{ij} = e^{-\lambda (r_{ij} - z_0)} \left[ C + f(\rho_{ij}) + f(\rho_{ji}) - A \left( \frac{r_{ij}}{z_0} \right)^{-6} \right]
\]

\[
\rho_{ij}^2 = r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_i)^2
\]

\[
\rho_{ji}^2 = r_{ij}^2 - (\mathbf{r}_{ij} \cdot \mathbf{n}_j)^2
\]

\[
f(\rho) = e^{-(\rho/\delta)^2} \sum_{n=0}^2 C_{2n}(\rho/\delta)^{2n}
\]

It is important to have a sufficiently large cutoff to ensure smooth forces and to include all the pairs to build the neighbor list for calculating the normals. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of \(V_{ij}\) (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for \(V_{ij}\) above. This is essential only when the taper function is turned off. The formula of taper function can be found in pair style \textit{ilp/graphene/hbn}.

\textbf{Note:} This potential (ILP) is intended for interlayer interactions between two different layers of graphene. To perform a realistic simulation, this potential must be used in combination with intralayer potential, such as \textit{AIREBO} or \textit{Tersoff} potential. To keep the intralayer properties unaffected, the interlayer interaction within the same layers should be avoided. Hence, each atom has to have a layer identifier such that atoms residing on the same layer interact via the appropriate intralayer potential and atoms residing on different layers interact via the ILP. Here, the molecule id is chosen as the layer identifier, thus a data file with the “full” atom style is required to use this potential.

The parameter file (e.g. CH.KC), is intended for use with \textit{metal units}, with energies in meV. Two additional parameters, \(S\), and \textit{rcut} are included in the parameter file. \(S\) is designed to facilitate scaling of energies. \textit{rcut} is designed to build the neighbor list for calculating the normals for each atom pair.

\textbf{Note:} Two new sets of parameters of KC potential for hydrocarbons, CH.KC (without the taper function) and CH_taper.KC (with the taper function) are presented in \cite{Ouyang1}. The energy for the KC potential with the taper function goes continuously to zero at the cutoff. The parameters in both CH.KC and CH_taper.KC provide a good description in both short- and long-range interaction regimes. While the original parameters (CC.KC) published in \cite{Kolmogorov} are only suitable for long-range interaction regime. This feature is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance). The benchmark tests and comparison of these parameters can be found in \cite{Ouyang1} and \cite{Ouyang2}.

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair\_style \textit{none}.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the \textit{compute pair} command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1. \(E_{vdW} = \text{vdW (attractive energy)}\)
2. \(E_{Rep} = \text{repulsive energy}\)

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:
compute 0 all pair kolmogorov/crespi/full
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw

20.113.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

20.113.5 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair potential requires the newton setting to be on for pair interactions.

The CH.KC potential file provided with LAMMPS (see the potentials folder) are parameterized for metal units. You can use this potential with any LAMMPS units, but you would need to create your own custom CC.KC potential file with all coefficients converted to the appropriate units.

20.113.6 Related commands

pair_coeff, pair_none, pair_style hybrid/overlay, pair_style drip, pair_style pair_lebedeva_z, pair_style kolmogorov/crespi/z, pair_style ilp/graphene/hbn.

20.113.7 Default

tap_flag = 0

20.114 pair_style kolmogorov/crespi/z command

20.114.1 Syntax

pair_style [hybrid/overlay ...] kolmogorov/crespi/z cutoff
20.114.2 Examples

```
pair_style hybrid/overlay kolmogorov/crespi/z 20.0
pair_coeff * * none
pair_coeff 1 2 kolmogorov/crespi/z CC.KC C C

pair_style hybrid/overlay rebo kolmogorov/crespi/z 14.0
pair_coeff * * rebo CH.rebo C C
pair_coeff 1 2 kolmogorov/crespi/z CC.KC C C
```

20.114.3 Description

The `kolmogorov/crespi/z` style computes the Kolmogorov-Crespi interaction potential as described in (Kolmogorov).

An important simplification is made, which is to take all normals along the z-axis.

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \\
V_{ij} = e^{-\lambda(r_{ij} - z_0)} \left[ C + f(\rho_{ij}) + f(\rho_{ji}) \right] - A \left( \frac{r_{ij}}{z_0} \right)^{-6} + A \left( \frac{\text{cutoff}}{z_0} \right)^{-6} \\
\rho_{ij}^2 = \rho_{ji}^2 = x_{ij}^2 + y_{ij}^2 \quad (n_i \equiv \hat{z}) \\
f(\rho) = e^{-(\rho/\delta)^2} \sum_{n=0}^{2} C_{2n} (\rho/\delta)^{2n}
\]

It is important to have a sufficiently large cutoff to ensure smooth forces. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of \(V_{ij}\) (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for \(V_{ij}\) above.

This potential is intended for interactions between two layers of graphene. Therefore, to avoid interaction between layers in multi-layered materials, each layer should have a separate atom type and interactions should only be computed between atom types of neighboring layers.

The parameter file (e.g. CC.KC), is intended for use with metal units, with energies in meV. An additional parameter, \(S\), is available to facilitate scaling of energies in accordance with (vanWijk).

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using `pair_style none`.

20.114.4 Restrictions

This fix is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

20.115 pair_style lcbop command

20.115.1 Syntax

```plaintext
pair_style lcbop
```

20.115.2 Examples

```plaintext
pair_style lcbop
pair_coeff * * ../potentials/C.lcbop C
```

20.115.3 Description

The lcbop pair style computes the long-range bond-order potential for carbon (LCBOP) of (Los and Fasolino). See section II in that paper for the analytic equations associated with the potential.

Only a single pair_coeff command is used with the lcbop style which specifies an LCBOP potential file with parameters for specific elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of LCBOP elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, if your LAMMPS simulation has 4 atom types and you want the first 3 to be C you would use the following pair_coeff command:

```plaintext
pair_coeff * * C.lcbop C C C NULL
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first C argument maps LAMMPS atom type 1 to the C element in the LCBOP file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a lcbop potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The parameters/coefficients for the LCBOP potential as applied to C are listed in the C.lcbop file to agree with the original (Los and Fasolino) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done carefully.
20.115.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to `binary restart files`, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

20.115.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

This pair potential requires the `newton` setting to be “on” for pair interactions.

The C.lcbop potential file provided with LAMMPS (see the `potentials` directory) is parameterized for metal `units`. You can use the LCBOP potential with any LAMMPS units, but you would need to create your own LCBOP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

```

20.116.2 Examples

```
pair_style hybrid/overlay lebedeva/z 20.0
pair_coeff * * none
pair_coeff 1 2 lebedeva/z CC.Lebedeva C C

pair_style hybrid/overlay rebo lebedeva/z 14.0
pair_coeff * * rebo CH.rebo C C
pair_coeff 1 2 lebedeva/z CC.Lebedeva C C
```
20.116.3 Description

The lebedeva/z style computes the Lebedeva interaction potential as described in \cite{Lebedeva2011}. An important simplification is made, which is to take all normals along the z-axis.

\[
E = \frac{1}{2} \sum_i \sum_{i \neq j} V_{ij} \\
V_{ij} = B e^{-\alpha (r_{ij} - z_0)} \\
+ C (1 + D_1 \rho_{ij}^2 + D_2 \rho_{ij}^4 e^{-\lambda_1 \rho_{ij}^2} e^{-\lambda_2 (z_{ij}^2 - z_0^2)}) \\
- A \left( \frac{z_0}{r_{ij}} \right)^6 + A \left( \frac{z_0}{r_c} \right)^6 \\
\rho_{ij}^2 = x_{ij}^2 + y_{ij}^2 \quad (n_i \equiv \hat{z})
\]

It is important to have a sufficiently large cutoff to ensure smooth forces. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of \(V_{ij}\) (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for \(V_{ij}\) above.

The parameter file (e.g. CC.Lebedeva), is intended for use with metal units, with energies in meV. An additional parameter, \(S\), is available to facilitate scaling of energies.

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style none.

20.116.4 Restrictions

pair_coeff  1 2 1.0 0.0 1.0 1.0 2.5
```

20.117.3 Description

Style `line/lj` treats particles which are line segments as a set of small spherical particles that tile the line segment length as explained below. Interactions between two line segments, each with N1 and N2 spherical particles, are calculated as the pairwise sum of N1*N2 Lennard-Jones interactions. Interactions between a line segment with N spherical particles and a point particle are treated as the pairwise sum of N Lennard-Jones interactions. See the `pair_style lj/cut` doc page for the definition of Lennard-Jones interactions.

The set of non-overlapping spherical sub-particles that represent a line segment are generated in the following manner. Their size is a function of the line segment length and the specified sub-particle size for that particle type. If a line segment has a length L and is of type I, then the number of spheres N that represent the segment is calculated as N = L/sizeI, rounded up to an integer value. Thus if L is not evenly divisible by sizeI, N is incremented to include one extra sphere. The centers of the spheres are spaced equally along the line segment. Imagine N+1 equally-space points, which include the 2 end points of the segment. The sphere centers are halfway between each pair of points.

The LJ interaction between 2 spheres on different line segments (or a sphere on a line segment and a point particles) is computed with sub-particle $\epsilon$, $\sigma$, and cutoff values that are set by the pair_coeff command, as described below. If the distance between the 2 spheres is greater than the sub-particle cutoff, there is no interaction. This means that some pairs of sub-particles on 2 line segments may interact, but others may not.

For purposes of creating the neighbor list for pairs of interacting line segments or lines/point particles, a regular particle-particle cutoff is used, as defined by the cutoff setting above in the pair_style command or overridden with an optional argument in the pair_coeff command for a type pair as discussed below. The distance between the centers of 2 line segments, or the center of a line segment and a point particle, must be less than this distance (plus the neighbor skin; see the neighbor command), for the pair of particles to be included in the neighbor list.

**Note:** This means that a too-short value for the cutoff setting can exclude a pair of particles from the neighbor list even if pairs of their sub-particle spheres would interact, based on the sub-particle cutoff specified in the pair_coeff command. E.g. sub-particles at the ends of the line segments that are close to each other. Which may not be what you want, since it means the ends of 2 line segments could pass through each other. It is up to you to specify a cutoff setting that is consistent with the length of the line segments you are using and the sub-particle cutoff settings.

For style `line/lj`, the following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- sizeI (distance units)
- sizeJ (distance units)
- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- subcutoff (distance units)
- cutoff (distance units)

The sizeI and sizeJ coefficients are the sub-particle sizes for line particles of type I and type J. They are used to define the N sub-particles per segment as described above. These coefficients are actually stored on a per-type basis. Thus if there are multiple pair_coeff commands that involve type I, as either the first or second atom type, you should use
consistent values for sizeI or sizeJ in all of them. If you do not do this, the last value specified for sizeI will apply to all segments of type I. If typeI or typeJ refers to point particles, the corresponding sizeI or sizeJ is ignored; it can be set to 0.0.

The $\epsilon$, $\sigma$, and subcutoff coefficients are used to compute an LJ interactions between a pair of sub-particles on 2 line segments (of type I and J), or between a sub particle/point particle pair. As discussed above, the subcutoff and cutoff params are different. The latter is only used for building the neighbor list when the distance between centers of two line segments or one segment and a point particle is calculated.

The cutoff coefficient is optional. If not specified, the global cutoff is used.

20.117.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I $\neq$ J, coefficients must be specified. No default mixing rules are used.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.117.5 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Defining particles to be line segments so they participate in line/line or line/particle interactions requires the use the atom_style line command.

20.117.6 Related commands

pair_coeff, pair_style tri/lj

20.117.7 Default

20.118 pair_style list command

20.118.1 Syntax

pair_style list listfile cutoff keyword

- listfile = name of file with list of pairwise interactions
- cutoff = global cutoff (distance units)
- keyword = optional flag nocheck or check (default is check)
20.118.2 Examples

```
pair_style list restraints.txt 200.0
pair_coeff * *
pair_style hybrid/overlay lj/cut 1.1225 list pair_list.txt 300.0
pair_coeff * * lj/cut 1.0 1.0
pair_coeff 3* 3* list
```

20.118.3 Description

Style `list` computes interactions between explicitly listed pairs of atoms with the option to select functional form and parameters for each individual pair. Because the parameters are set in the list file, the `pair_coeff` command has no parameters (but still needs to be provided). The `check` and `nocheck` keywords enable/disable a test that checks whether all listed bonds were present and computed.

This pair style can be thought of as a hybrid between bonded, non-bonded, and restraint interactions. It will typically be used as an additional interaction within the `hybrid/overlay` pair style. It currently supports three interaction styles: a 12-6 Lennard-Jones, a Morse and a harmonic potential.

The format of the list file is as follows:

- one line per pair of atoms
- empty lines will be ignored
- comment text starts with a ‘#’ character
- line syntax: `ID1 ID2 style coeffs cutoff`

```
ID1 = atom ID of first atom
ID2 = atom ID of second atom
style = style of interaction
coeffs = list of coeffs
cutoff = cutoff for interaction (optional)
```

The cutoff parameter is optional. If not specified, the global cutoff is used.

Here is an example file:

```
# this is a comment
15 259 lj126 1.0 1.0 50.0
15 603 morse 10.0 1.2 2.0 10.0 # and another comment
18 470 harmonic 50.0 1.2 5.0
```

The style `lj126` computes pairwise interactions with the formula

\[ E = 4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \]

for \( r < r_c \)

and the coefficients:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)

The style `morse` computes pairwise interactions with the formula

\[ E = D_0 \left[ e^{-2\alpha (r-r_0)} - e^{-\alpha (r-r_0)} \right] \]

for \( r < r_c \).
and the coefficients:

- $D_0$ (energy units)
- $\alpha$ (1/distance units)
- $r_0$ (distance units)

The style *harmonic* computes pairwise interactions with the formula

$$E = K(r - r_0)^2$$

and the coefficients:

- $K$ (energy units)
- $r_0$ (distance units)

Note that the usual 1/2 factor is included in $K$.

### 20.118.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing since all parameters are explicit for each pair.

The *pair_modify* shift option is supported by this pair style.

The *pair_modify* table and tail options are not relevant for this pair style.

This pair style does not write its information to binary restart files, so *pair_style* and *pair_coeff* commands need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 20.118.5 Restrictions

This pair style does not use a neighbor list and instead identifies atoms by their IDs. This has two consequences: 1) The cutoff has to be chosen sufficiently large, so that the second atom of a pair has to be a ghost atom on the same node on which the first atom is local; otherwise the interaction will be skipped. You can use the *check* option to detect, if interactions are missing. 2) Unlike other pair styles in LAMMPS, an atom I will not interact with multiple images of atom J (assuming the images are within the cutoff distance), but only with the nearest image.

This style is part of the USER-MISC package. It is only enabled if LAMMPS is build with that package. See the *Build package* doc page on for more info.

### 20.118.6 Related commands

*pair_coeff*, *pair_style hybrid/overlay*, *pair_style lj/cut*, *pair_style morse*, *bond_style harmonic*
20.119.1 Syntax

```
pair_style  style  args
```

- `style = lj/cut`
- `args = list of arguments for a particular style`

`lj/cut args = cutoff`

`cutoff = global cutoff for Lennard Jones interactions (distance units)`

20.119.2 Examples

```
pair_style  lj/cut  2.5
pair_coeff   *   *   1   1
pair_coeff   1   1   1.1   2.8
```

20.119.3 Description

The `lj/cut` styles compute the standard 12/6 Lennard-Jones potential, given by

\[ E = 4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \quad r < r_c \]

`r_c` is the cutoff.

See the `lj/cut/coul` styles to add a Coulombic pairwise interaction and the `lj/cut/tip4p` styles to add the TIP4P water model.

20.119.4 Coefficients

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- LJ cutoff (distance units)
Note that $\sigma$ is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at $2^{\frac{1}{6}}\sigma$.

The last coefficient is optional. If not specified, the global LJ cutoff specified in the pair_style command are used.

A version of these styles with a soft core, lj/cut/soft, suitable for use in free energy calculations, is part of the USER-FEP package and is documented with the pair_style */soft styles.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.119.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I ≠ J, the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

All of the lj/cut pair styles support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction.

All of the lj/cut pair styles support the pair_modify tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

All of the lj/cut pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/cut pair styles support the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the pair keyword of run_style respa. See the run_style command for details.

20.120.2 Examples

```
pair_style lj96/cut 2.5
pair_coeff * * 1.0 1.0 4.0
pair_coeff 1 1 1.0 1.0
```

20.120.3 Description

The lj96/cut style compute a 9/6 Lennard-Jones potential, instead of the standard 12/6 potential, given by

\[ E = 4\epsilon \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^6 \]  \quad r < r_c

\(r_c\) is the cutoff.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

• \(\epsilon\) (energy units)
• \(\sigma\) (distance units)
• cutoff (distance units)

The last coefficient is optional. If not specified, the global LJ cutoff specified in the pair_style command is used.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.120.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style supports the pair_modify tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the run_style command for details.

### 20.120.5 Restrictions

none

### 20.120.6 Related commands

pair_coeff

### 20.120.7 Default

none

### 20.121 pair_style lj/cubic command

Accelerator Variants: lj/cubic/gpu, lj/cubic/omp
20.121.1 Syntax

```
pair_style lj/cubic
```

20.121.2 Examples

```
pair_style lj/cubic
pair_coeff * * 1.0 0.8908987
```

20.121.3 Description

The `lj/cubic` style computes a truncated LJ interaction potential whose energy and force are continuous everywhere. Inside the inflection point the interaction is identical to the standard 12/6 Lennard-Jones potential. The LJ function outside the inflection point is replaced with a cubic function of distance. The energy, force, and second derivative are continuous at the inflection point. The cubic coefficient $A_3$ is chosen so that both energy and force go to zero at the cutoff distance. Outside the cutoff distance the energy and force are zero.

$$
E = u_{LJ}(r) \quad r \leq r_s
$$

$$
= u_{LJ}(r_s) + (r - r_s)u'_{LJ}(r_s) - \frac{1}{6} A_3(r - r_s)^3 \quad r_s < r \leq r_c
$$

$$
= 0 \quad r > r_c
$$

The location of the inflection point $r_s$ is defined by the LJ diameter, $r_s/\sigma = (26/7)^{1/6}$. The cutoff distance is defined by $r_c/r_s = 67/48$ or $r_c/\sigma = 1.737...$. The analytic expression for the the cubic coefficient $A_3 r_{min}^3 / \epsilon = 27.93...$ is given in the paper by Holian and Ravelo (Holian).

This potential is commonly used to study the shock mechanics of FCC solids, as in Ravelo et al. (Ravelo).

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)

Note that $\sigma$ is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum, which is located at $r_{min} = 2^{1/6} \sigma$. In the above example, $\sigma = 0.8908987$, so $r_{min} = 1.0$.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
20.121.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I ≠ J, the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

The lj/cubic pair style does not support the pair_modify shift option, since pair interaction is already smoothed to 0.0 at the cutoff.

The pair_modify table option is not relevant for this pair style.

The lj/cubic pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

The lj/cubic pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/cubic pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

```

20.127.3 Description

The *lj/cut/coul* styles compute the standard 12/6 Lennard-Jones potential, given by

$$E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \quad r < r_c$$

$r_c$ is the cutoff.

Style *lj/cut/coul/cut* adds a Coulombic pairwise interaction given by

$$E = \frac{C q_i q_j}{\epsilon r} \quad r < r_c$$

where $C$ is an energy-conversion constant, $q_i$ and $q_j$ are the charges on the 2 atoms, and $\epsilon$ is the dielectric constant which can be set by the *dielectric* command. If one cutoff is specified in the pair_style command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

Style *lj/cut/coul/debye* adds an additional exp() damping factor to the Coulombic term, given by

$$E = \frac{C q_i q_j}{\epsilon r} \exp(-\kappa r) \quad r < r_c$$

where $\kappa$ is the inverse of the Debye length. This potential is another way to mimic the screening effect of a polar solvent.
Style *lj/cut/coul/dsf* computes the Coulombic term via the damped shifted force model described in *Fennell*, given by:

\[
E = q_i q_j \left[ \frac{\text{erfc}(\alpha r)}{r} - \frac{\text{erfc}(\alpha r_c)}{r_c} + \left( \frac{\text{erfc}(\alpha r_c)}{r_c} + \frac{2\alpha \exp(-\alpha^2 r_c^2)}{\sqrt{\pi}} \right) \right] (r - r_c) \quad r < r_c
\]

where \( \alpha \) is the damping parameter and \( \text{erfc}() \) is the complementary error-function. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise \( 1/r \) summation. The potential is based on Wolf summation, proposed as an alternative to Ewald summation for condensed phase systems where charge screening causes electrostatic interactions to become effectively short-ranged. In order for the electrostatic sum to be absolutely convergent, charge neutralization within the cutoff radius is enforced by shifting the potential through placement of image charges on the cutoff sphere. Convergence can often be improved by setting \( \alpha \) to a small non-zero value.

Styles *lj/cut/coul/long* and *lj/cut/coul/msm* compute the same Coulombic interactions as style *lj/cut/coul/cut* except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the *kspace_style* command and its *ewald* or *pppm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

Style *coul/wolf* adds a Coulombic pairwise interaction via the Wolf summation method, described in *Wolf*, given by:

\[
E_i = \frac{1}{2} \sum_{j \neq i} q_i q_j \text{erfc}(\alpha r_{ij}) + \frac{1}{2} \sum_{j \neq i} q_i q_j \text{erf}(\alpha r_{ij}) \quad r < r_c
\]

where \( \alpha \) is the damping parameter, and \( \text{erfc}() \) is the complementary error-function terms. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise \( 1/r \) summation. With a manipulation of adding and subtracting a self term (for \( i = j \)) to the first and second term on the right-hand-side, respectively, and a small enough \( \alpha \) damping parameter, the second term shrinks and the potential becomes a rapidly-converging real-space summation. With a long enough cutoff and small enough \( \alpha \) parameter, the energy and forces calculated by the Wolf summation method approach those of the Ewald sum. So it is a means of getting effective long-range interactions with a short-range potential.

### 20.127.4 Coefficients

For all of the *lj/cut/coul* pair styles, the following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

Note that \( \sigma \) is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at \( 2^{1/6} \sigma \).

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the *pair_style* command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

For *lj/cut/coul/long* and *lj/cut/coul/msm* only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the *pair_style* command.

A version of these styles with a soft core, *lj/cut/coul/soft* and *lj/cut/coul/long/soft*, suitable for use in free energy calculations, is part of the USER-FEP package and is documented with the *pair_style */soft* styles.
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.127.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

All of the lj/cut pair styles support the `pair_modify` shift option for the energy of the Lennard-Jones portion of the pair interaction.

The lj/cut/coul/long pair styles support the `pair_modify` table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the lj/cut pair styles support the `pair_modify` tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

All of the lj/cut pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/cut/coul/long pair styles support the use of the `inner`, `middle`, and `outer` keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the `pair` keyword of run_style respa. See the run_style command for details.

### 20.127.6 Restrictions

The lj/cut/coul/long styles are part of the KSPACE package. These styles are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

20.129.3 Description

The \( \text{lj/cut/tip4p} \) styles compute the standard 12/6 Lennard-Jones potential, given by

\[
E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \quad r < r_c
\]

\( r_c \) is the cutoff.

They add Coulombic pairwise interactions given by

\[
E = \frac{Cq_i q_j}{\epsilon r} \quad r < r_c
\]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, and \( \epsilon \) is the dielectric constant which can be set by the \text{dielectric} command. If one cutoff is specified in the \text{pair_style} command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

Style \( \text{lj/cut/tip4p/long} \) compute the same Coulombic interactions as style \( \text{lj/cut/tip4p/cut} \) except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the \text{kspace_style} command and its \text{ewald} or \text{pppm} option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

The \( \text{lj/cut/tip4p} \) styles implement the TIP4P water model of (Jorgensen), which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as pair_style arguments. Style \( \text{lj/cut/tip4p/cut} \) uses a cutoff for Coulomb interactions; style \( \text{lj/cut/tip4p/long} \) is for use with a long-range Coulombic solver (Ewald or PPPM).

Note: For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

See the \text{Howto tip4p} doc page for more information on how to use the TIP4P pair styles and lists of parameters to set. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance \( 2^*\text{qdist} \) when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff \( \geq \) Coulombic cutoff + \( 2^*\text{qdist} \), to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

20.129.4 Coefficients

For all of the \( \text{lj/cut} \) pair styles, the following coefficients must be defined for each pair of atoms types via the \text{pair_coeff} command as in the examples above, or in the data file or restart files read by the \text{read_data} or \text{read_restart} commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- LJ cutoff (distance units)

Note that \( \sigma \) is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at 2\( \frac{\sqrt{2}}{6} \)\( \sigma \).

The last coefficient is optional. If not specified, the global LJ cutoff specified in the \text{pair_style} command is used.
For \textit{lj/cut} and \textit{lj/cut/coul} only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the \textit{pair_style} command.

A version of these styles with a soft core, \textit{lj/cut/coul/soft}, suitable for use in free energy calculations, is part of the USER-FEP package and is documented with the \textit{pair_style} */soft styles.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix command-line switch} when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

### 20.129.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs \textit{I} and \textit{J} and \textit{I} \neq \textit{J}, the epsilon and sigma coefficients and cutoff distance for all of the \textit{lj/cut} pair styles can be mixed. The default mix value is \textit{geometric}. See the “\textit{pair_modify}” command for details.

All of the \textit{lj/cut} pair styles support the \textit{pair_modify} shift option for the energy of the Lennard-Jones portion of the pair interaction.

The \textit{lj/cut/coul/long} and \textit{lj/cut/coul} pair styles support the \textit{pair_modify} table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the \textit{lj/cut} pair styles support the \textit{pair_modify} tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

All of the \textit{lj/cut} pair styles write their information to \textit{binary restart files}, so \textit{pair_style} and \textit{pair_coeff} commands do not need to be specified in an input script that reads a restart file.

The \textit{lj/cut} and \textit{lj/cut/coul/long} pair styles support the use of the \textit{inner}, \textit{middle}, and \textit{outer} keywords of the \textit{run_style respa} command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the \textit{pair} keyword of \textit{run_style respa}. See the \textit{run_style} command for details.

### 20.129.6 Restrictions

The \textit{lj/cut/coul/long} styles are part of the KSPACE package. The \textit{lj/cut/coul} style is part of the MOLECULE package. These styles are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

</tbody>
</table>

20.131.3 Description

Style lj/expand computes a LJ interaction with a distance shifted by delta which can be useful when particles are of different sizes, since it is different that using different sigma values in a standard LJ formula:

\[
E = 4\varepsilon \left[ \left( \frac{\sigma}{r - \Delta} \right)^{12} - \left( \frac{\sigma}{r - \Delta} \right)^6 \right] \quad r < r_c + \Delta
\]

\(r_c\) is the cutoff which does not include the \(\Delta\) distance. I.e. the actual force cutoff is the sum of \(r_c + \Delta\).

For all of the lj/expand pair styles, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:
• \( \epsilon \) (energy units)
• \( \sigma \) (distance units)
• \( \Delta \) (distance units)
• cutoff (distance units)

The \( \Delta \) values can be positive or negative. The last coefficient is optional. If not specified, the global LJ cutoff is used.

For \( \text{lj/expand/coul/long} \) only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix} command-line switch when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

### 20.131.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \(!=\) J, the epsilon, sigma, and shift coefficients and cutoff distance for this pair style can be mixed. Shift is always mixed via an \textit{arithmetic} rule. The other coefficients are mixed according to the pair_modify mix value. The default mix value is \textit{geometric}. See the “pair_modify” command for details.

This pair style supports the \textit{pair_modify} shift option for the energy of the pair interaction.

The \textit{pair_modify} table option is not relevant for this pair style.

This pair style supports the \textit{pair_modify} tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to \textit{binary restart files}, so \textit{pair_style} and \textit{pair_coeff} commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the \textit{pair} keyword of the \textit{run_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

20.133.3 Description

Style `lj/long/coul/long` computes the standard 12/6 Lennard-Jones potential:

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \quad r < r_c \]

with \( \epsilon \) and \( \sigma \) being the usual Lennard-Jones potential parameters, plus the Coulomb potential, given by:

\[ E = \frac{C q_i q_j}{\epsilon r} \quad r < r_c \]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, \( \epsilon \) is the dielectric constant which can be set by the `dielectric` command, and \( r_c \) is the cutoff. If one cutoff is specified in the `pair_style` command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

The purpose of this pair style is to capture long-range interactions resulting from both attractive 1/r^6 Lennard-Jones and Coulombic 1/r interactions. This is done by use of the `flag_lj` and `flag_coul` settings. The In ’t Veld paper has more details on when it is appropriate to include long-range 1/r^6 interactions, using this potential.

Style `lj/long/tip4p/long` implements the TIP4P water model of (Jorgensen), which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as `pair_style` arguments.

Note: For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

See the Howto tip4p doc page for more information on how to use the TIP4P pair style. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance 2*qdist when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff \( \geq \) Coulombic cutoff + 2*qdist, to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

If `flag_lj` is set to `long`, no cutoff is used on the LJ 1/r^6 dispersion term. The long-range portion can be calculated by using the `kspace_style ewald/disp` or `pppm/disp` commands. The specified LJ cutoff then determines which portion of the LJ interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the Kspace style. If `flag_lj` is set to `cut`, the LJ interactions are simply cutoff, as with `pair_style lj/cut`.

If `flag_coul` is set to `long`, no cutoff is used on the Coulombic interactions. The long-range portion can be calculated by using any of several `kspace_style` command options such as `pppm` or `ewald`. Note that if `flag_lj` is also set to `long`, then
the ewald/disp or pppm/disp Kspace style needs to be used to perform the long-range calculations for both the LJ and Coulombic interactions. If flag_coul is set to off, Coulombic interactions are not computed.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

Note that sigma is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at $2^{(1/6)} \sigma$.

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

Note that if you are using flag_lj set to long, you cannot specify a LJ cutoff for an atom type pair, since only one global LJ cutoff is allowed. Similarly, if you are using flag_coul set to long, you cannot specify a Coulombic cutoff for an atom type pair, since only one global Coulombic cutoff is allowed.

For lj/long/tip4p/long only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

A version of these styles with a soft core, lj/cut/soft, suitable for use in free energy calculations, is part of the USER-FEP package and is documented with the pair_style */soft styles. The version with soft core is only available if LAMMPS was built with that package. See the Build package doc page for more info.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.133.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/long pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

These pair styles support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction, assuming flag_lj is cut.

These pair styles support the pair_modify table and table/disp options since they can tabulate the short-range portion of the long-range Coulombic and dispersion interactions.
Thes pair styles do not support the pair_modify tail option for adding a long-range tail correction to the Lennard-Jones portion of the energy and pressure.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The pair lj/long/coul/long styles support the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the run_style command for details.

## 20.133.5 Restrictions

These styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

## 20.133.6 Related commands

pair_coeff

## 20.133.7 Default

none

---

## 20.134 pair_style lj/smooth command

Accelerator Variants: lj/smooth/omp

### 20.134.1 Syntax

```
pair_style lj/smooth Rin Rc
```

- Rin = inner cutoff beyond which force smoothing will be applied (distance units)
- Rc = outer cutoff for lj/smooth interactions (distance units)
20.134.2 Examples

```
pair_style lj/smooth 8.0 10.0
pair_coeff * * 10.0 1.5
pair_coeff 1 1 20.0 1.3 7.0 9.0
```

20.134.3 Description

Style \( \text{lj/smooth} \) computes a LJ interaction with a force smoothing applied between the inner and outer cutoff.

\[
E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_{in}
\]

\[
F = C_1 + C_2(r - r_{in}) + C_3(r - r_{in})^2 + C_4(r - r_{in})^3 \quad r_{in} < r < r_c
\]

The polynomial coefficients \( C_1, C_2, C_3, C_4 \) are computed by LAMMPS to cause the force to vary smoothly from the inner cutoff \( r_{in} \) to the outer cutoff \( r_c \).

At the inner cutoff the force and its first derivative will match the non-smoothed LJ formula. At the outer cutoff the force and its first derivative will be 0.0. The inner cutoff cannot be 0.0.

**Note:** this force smoothing causes the energy to be discontinuous both in its values and first derivative. This can lead to poor energy conservation and may require the use of a thermostat. Plot the energy and force resulting from this formula via the `pair_write` command to see the effect.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- \( r_{in} \) (distance units)
- \( r_c \) (distance units)

The last 2 coefficients are optional inner and outer cutoffs. If not specified, the global values for \( r_{in} \) and \( r_c \) are used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
20.134.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon, sigma, Rin coefficients and the cutoff distance for this pair style can be mixed. Rin is a cutoff value and is mixed like the cutoff. The other coefficients are mixed according to the pair_modify mix option. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure, since the energy of the pair interaction is smoothed to 0.0 at the cutoff.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.134.5 Restrictions

none

20.134.6 Related commands

pair_coeff, pair lj/smooth/linear

20.134.7 Default

none

20.135 pair_style lj/smooth/linear command

Accelerator Variants: lj/smooth/linear/omp

20.135.1 Syntax

```
pair_style lj/smooth/linear cutoff
```

- cutoff = global cutoff for Lennard-Jones interactions (distance units)
20.135.2 Examples

```plaintext
pair_style lj/smooth/linear 2.5
pair_coeff * * 1.0 1.0
pair_coeff 1 1 0.3 3.0 9.0
```

20.135.3 Description

Style `lj/smooth/linear` computes a truncated and force-shifted LJ interaction (aka Shifted Force Lennard-Jones) that combines the standard 12/6 Lennard-Jones function and subtracts a linear term based on the cutoff distance, so that both, the potential and the force, go continuously to zero at the cutoff $R_c$ (Toxvaerd):

$$
\phi(r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right]
$$

$$
E(r) = \phi(r) - \phi(R_c) - (r - R_c) \frac{d\phi}{dr} \bigg|_{r=R_c} \quad r < R_c
$$

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global LJ cutoff specified in the `pair_style` command is used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.135.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the `pair_modify` shift option for the energy of the pair interaction, since it goes to 0.0 at the cutoff by construction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure, since the energy of the pair interaction is smoothed to 0.0 at the cutoff.
This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

- `args = list of arguments for a particular style`

```
lj/switch3/coulgauss/long args = cutoff (cutoff2) width
    cutoff  = global cutoff for LJ (and Coulombic if only 1 arg) (distance units)
    cutoff2 = global cutoff for Coulombic (optional) (distance units)
    width  = width parameter of the smoothing function (distance units)
```

#### 20.136.2 Examples

```
pair_style lj/switch3/coulgauss/long 12.0 3.0
pair_coeff 1 0.2 2.5 1.2

pair_style lj/switch3/coulgauss/long 12.0 10.0 3.0
pair_coeff 1 0.2 2.5 1.2
```
20.136.3 Description

The \textit{lj/switch3/coulgauss} style evaluates the LJ vdW potential

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \]

which goes smoothly to zero at the cutoff \( r_c \) as defined by the switching function

\[ S_3(r) = \begin{cases} 
1 & \text{if } r < r_c - w \\
3x^2 - 2x^3 & \text{if } r < r_c \text{ with } x = \frac{r_c - r}{w} \\
0 & \text{if } r > r_c
\end{cases} \]

where \( w \) is the width defined in the arguments. This potential is combined with Coulomb interaction between Gaussian charge densities:

\[ E = \frac{q_i q_j \text{erf} \left( \frac{r}{\sqrt{\gamma_i^2 + \gamma_j^2}} \right)}{cr_{ij}} \]

where \( q_i \) and \( q_j \) are the charges on the 2 atoms, \( \epsilon \) is the dielectric constant which can be set by the \textit{dielectric} command, \( \gamma_i \) and \( \gamma_j \) are the widths of the Gaussian charge distribution and \( \text{erf}() \) is the error-function. This style has to be used in conjunction with the \textit{kspace_style} command.

If one cutoff is specified it is used for both the vdW and Coulomb terms. If two cutoffs are specified, the first is used as the cutoff for the vdW terms, and the second is the cutoff for the Coulombic term.

The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands:

- \( \epsilon \) (energy)
- \( \sigma \) (distance)
- \( \gamma \) (distance)

20.136.4 Mixing, shift, table, tail correction, restart, rRESPA info

Shifting the potential energy is not necessary because the switching function ensures that the potential is zero at the cut-off.

20.136.5 Restrictions

These styles are part of the USER-YAFF package. They are only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

20.137 pair_style local/density command

20.137.1 Syntax

pair_style style arg

- style = local/density
- arg = name of file containing tabulated values of local density and the potential

20.137.2 Examples

pair_style local/density benzene_water.localdensity.table

pair_style hybrid/overlay table spline 500 local/density

pair_coeff * * local/density benzene_water.localdensity.table

20.137.3 Description

The local density (LD) potential is a mean-field manybody potential, and, in some sense, a generalization of embedded atom models (EAM). The name “local density potential” arises from the fact that it assigns an energy to an atom depending on the number of neighboring atoms of given type around it within a predefined spherical volume (i.e., within a cutoff). The bottom-up coarse-graining (CG) literature suggests that such potentials can be widely useful in capturing effective multibody forces in a computationally efficient manner so as to improve the quality of CG models of implicit solvation:ref:(Sanyal1) <Sanyal1> and phase-segregation in liquid mixtures:ref:(Sanyal2) <Sanyal2>, and provide guidelines to determine the extent of manybody correlations present in a CG model.:ref:(Rosenberger) <Rosenberger>

The LD potential in LAMMPS is primarily intended to be used as a corrective potential over traditional pair potentials in bottom-up CG models, i.e., as a hybrid pair style with other explicit pair interaction terms (e.g., table spline, Lennard Jones, etc.). Because the LD potential is not a pair potential per se, it is implemented simply as a single auxiliary file with all specifications that will be read upon initialization.

Note: Thus when used as the only interaction in the system, there is no corresponding pair_coeff command and when used with other pair styles using the hybrid/overlay option, the corresponding pair_coeff command must be supplied as placeholders for the atom types.

System with a single CG atom type:

A system of a single atom type (e.g., LJ argon) with a single local density (LD) potential would have an energy given by:

\[ U_{LD} = \sum_i F(\rho_i) \]
where \( \rho_i \) is the LD at atom \( i \) and \( F(\rho) \) is similar in spirit to the embedding function used in EAM potentials. The LD at atom \( i \) is given by the sum

\[
\rho_i = \sum_{j \neq i} \varphi(r_{ij})
\]

where \( \varphi \) is an indicator function that is one at \( r=0 \) and zero beyond a cutoff distance \( R_2 \). The choice of the functional form of \( \varphi \) is somewhat arbitrary, but the following piecewise cubic function has proven sufficiently general: (Sanyal1), (Sanyal2) (Rosenberger)

\[
\varphi(r) =
\begin{cases}
1 & r \leq R_1 \\
c_0 + c_2 r^2 + c_4 r^4 + c_6 r^6 & r \in (R_1, R_2) \\
0 & r \geq R_2
\end{cases}
\]

The constants \( c \) are chosen so that the indicator function smoothly interpolates between 1 and 0 between the distances \( R_1 \) and \( R_2 \), which are called the inner and outer cutoffs, respectively. Thus \( \varphi \) satisfies \( \varphi(R_1) = 1, \varphi(R_2) = \varphi'(r=R_1) = \varphi'(r=R_2) = 0 \). The embedding function \( F(\rho) \) may or may not have a closed-form expression. To maintain generality, it is practically represented with a spline-interpolated table over a predetermined range of \( \rho \). Outside of that range it simply adopts zero values at the endpoints.

It can be shown that the total force between two atoms due to the LD potential takes the form of a pair force, which motivates its designation as a LAMMPS pair style. Please see (Sanyal1) for details of the derivation.

**Systems with arbitrary numbers of atom types:**

The potential is easily generalized to systems involving multiple atom types:

\[
U_{LD} = \sum_i a_\alpha F(\rho_i)
\]

with the LD expressed as

\[
\rho_i = \sum_{j \neq i} b_\beta \varphi(r_{ij})
\]

where \( \alpha \) gives the type of atom \( i \), \( \beta \) the type of atom \( j \), and the coefficients \( a \) and \( b \) filter for atom types as specified by the user. \( a \) is called the central atom filter as it determines to which atoms the potential applies; \( a_\alpha = 1 \) if the LD potential applies to atom type \( \alpha \) else zero. On the other hand, \( b \) is called the neighbor atom filter because it specifies which atom types to use in the calculation of the LD; \( b_\beta = 1 \) if atom type \( \beta \) contributes to the LD and zero otherwise.

**Note:** Note that the potentials need not be symmetric with respect to atom types, which is the reason for two distinct sets of coefficients \( a \) and \( b \). An atom type may contribute to the LD but not the potential, or to the potential but not the LD. Such decisions are made by the user and should (ideally) be motivated on physical grounds for the problem at hand.

**General form for implementation in LAMMPS:**

Of course, a system with many atom types may have many different possible LD potentials, each with their own atom type filters, cutoffs, and embedding functions. The most general form of this potential as implemented in the pair_style local/density is:

\[
U_{LD} = \sum_k U_{LD}^{(k)} = \sum_i \left[ \sum_k a_\alpha^{(k)} F^{(k)} \left( \rho_i^{(k)} \right) \right]
\]

1882 Chapter 20. Pair Styles
where, $k$ is an index that spans the (arbitrary) number of applied LD potentials $N_{LD}$. Each LD is calculated as before with:

$$\rho_i^{(k)} = \sum_j b_j^{(k)} \varphi_j^{(k)}(r_{ij})$$

The superscript on the indicator function $\varphi$ simply indicates that it is associated with specific values of the cutoff distances $R_1(k)$ and $R_2(k)$. In summary, there may be $N_{LD}$ distinct LD potentials. With each potential type $(k)$, one must specify:

- the inner and outer cutoffs as $R_1$ and $R_2$
- the central type filter $a(k)$, where $k = 1,2, \ldots N_{LD}$
- the neighbor type filter $b(k)$, where $k = 1,2, \ldots N_{LD}$
- the LD potential function $F(k)(\rho)$, typically as a table that is later spline-interpolated

Tabulated input file format:

| Line 1: | comment or blank (ignored) |
| Line 2: | comment or blank (ignored) |
| Line 3: | $N_{LD}$ $N_{rho}$ (# of LD potentials and # of tabulated values, single space separated) |
| Line 4: | blank (ignored) |
| Line 5: | $R_1(k)$ $R_2(k)$ (lower and upper cutoffs, single space separated) |
| Line 6: | central-types (central atom types, single space separated) |
| Line 7: | neighbor-types (neighbor atom types single space separated) |
| Line 8: | $\rho_{min}$ $\rho_{max}$ $drho$ (min, max and diff. in tabulated $\rho$ values, single space separated) |
| Line 9: | $F(k)(\rho_{min} + 0.drho)$ |
| Line 10: | $F(k)(\rho_{min} + 1.drho)$ |
| Line 11: | $F(k)(\rho_{min} + 2.drho)$ |
| ... | |
| Line 9+$N_{rho}$: | $F(k)(\rho_{min} + N_{rho} . drho)$ |
| Line 10+$N_{rho}$: | blank (ignored) |

Block 2

Block 3

Block $N_{LD}$

Lines 5 to 9+$N_{rho}$ constitute the first block. Thus the input file is separated (by blank lines) into $N_{LD}$ blocks each representing a separate LD potential and each specifying its own upper and lower cutoffs, central and neighbor atoms, and potential. In general, blank lines anywhere are ignored.
20.137.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support automatic mixing. For atom type pairs $\alpha$, $\beta$ and $\alpha \neq \beta$, even if LD potentials of type $(\alpha, \alpha)$ and $(\beta, \beta)$ are provided, you will need to explicitly provide LD potential types $(\alpha, \beta)$ and $(\beta, \alpha)$ if need be. (Here, the notation $(\alpha, \beta)$ means that $\alpha$ is the central atom to which the LD potential is applied and $\beta$ is the neighbor atom which contributes to the LD potential on $\alpha$).

This pair style does not support the pair_modify shift, table, and tail options.

The local/density pair style does not write its information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

20.137.5 Restrictions

The local/density pair style is a part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.138 pair_style lubricate command

Accelerator Variants: lubricate/omp

20.139 pair_style lubricate/poly command

Accelerator Variants: lubricate/poly/omp
20.139.1 Syntax

```plaintext
pair_style style mu flaglog flagfld cutinner cutoff flagHI flagVF
```

- **style = lubricate** or **lubricate/poly**
- **mu =** dynamic viscosity (dynamic viscosity units)
- **flaglog =** 0/1 to exclude/include log terms in the lubrication approximation
- **flagfld =** 0/1 to exclude/include Fast Lubrication Dynamics (FLD) effects
- **cutinner =** inner cutoff distance (distance units)
- **cutoff =** outer cutoff for interactions (distance units)
- **flagHI (optional) =** 0/1 to exclude/include 1/r hydrodynamic interactions
- **flagVF (optional) =** 0/1 to exclude/include volume fraction corrections in the long-range isotropic terms

20.139.2 Examples

(all assume radius = 1)

```plaintext
pair_style lubricate 1.5 1 1 2.01 2.5
pair_coeff 1 1 2.05 2.8
pair_coeff * *
pair_style lubricate 1.5 1 1 2.01 2.5
pair_coeff * *
variable mu equal ramp(1,2)
fix 1 all adapt 1 pair lubricate mu * * v_mu
```

20.139.3 Description

Styles **lubricate** and **lubricate/poly** compute hydrodynamic interactions between mono-disperse finite-size spherical particles in a pairwise fashion. The interactions have 2 components. The first is Ball-Melrose lubrication terms via the formulas in *(Ball and Melrose)*

\[
W = -a_{sq} \left| (v_1 - v_2) \cdot nn \right|^2 - a_{sh} \left| (\omega_1 + \omega_2) \cdot (I - nn) - 2\Omega_N \right|^2 - \\
a_{pu} \left| (\omega_1 - \omega_2) \cdot (I - nn) \right|^2 - a_{tw} \left| (\omega_1 - \omega_2) \cdot nn \right|^2 , \quad r < r_c
\]

\[
\Omega_N = n \times (v_1 - v_2)/r
\]

which represents the dissipation $W$ between two nearby particles due to their relative velocities in the presence of a background solvent with viscosity $mu$. Note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity.

The $A_{sq}$ (squeeze) term is the strongest and is included if **flagHI** is set to 1 (default). It scales as $1/gap$ where gap is the separation between the surfaces of the 2 particles. The $A_{sh}$ (shear) and $A_{pu}$ (pump) terms are only included if **flaglog** is set to 1. They are the next strongest interactions, and the only other singular interaction, and scale as log(gap). Note that **flaglog = 1** and **flagHI = 0** is invalid, and will result in a warning message, after which **flagHI** will be set to 1. The $A_{tw}$ (twist) term is currently not included. It is typically a very small contribution to the lubrication forces.

The **flagHI** and **flagVF** settings are optional. Neither should be used, or both must be defined.
Cutinner sets the minimum center-to-center separation that will be used in calculations irrespective of the actual separation. Cutoff is the maximum center-to-center separation at which an interaction is computed. Using a cutoff less than 3 radii is recommended if flaglog is set to 1.

The other component is due to the Fast Lubrication Dynamics (FLD) approximation, described in (Kumar), which can be represented by the following equation

$$F^H = -R_{FU}(U - U^\infty) + R_{FE}E^\infty$$

where $U$ represents the velocities and angular velocities of the particles, $U^\infty$ represents the velocity and the angular velocity of the undisturbed fluid, and $E^\infty$ represents the rate of strain tensor of the undisturbed fluid with viscosity $\mu$. Again, note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity. Volume fraction corrections to $R_{FU}$ are included as long as flagVF is set to 1 (default).

**Note:** When using the FLD terms, these pair styles are designed to be used with explicit time integration and a correspondingly small timestep. Thus either fix nve/sphere or fix nve/asphere should be used for time integration. To perform implicit FLD, see the pair_style lubricateU command.

Style lubricate requires monodisperse spherical particles; style lubricate/poly allows for polydisperse spherical particles.

The viscosity $\mu$ can be varied in a time-dependent manner over the course of a simulation, in which case the pair_style setting for $\mu$ will be overridden. See the fix adapt command for details.

If the suspension is sheared via the fix deform command then the pair style uses the shear rate to adjust the hydrodynamic interactions accordingly. Volume changes due to fix deform are accounted for when computing the volume fraction corrections to $R_{FU}$.

When computing the volume fraction corrections to $R_{FU}$, the presence of walls (whether moving or stationary) will affect the volume fraction available to colloidal particles. This is currently accounted for with the following types of walls: wall/lj93, wall/lj126, wall/colloid, and wall/harmonic. For these wall styles, the correct volume fraction will be used when walls do not coincide with the box boundary, as well as when walls move and thereby cause a change in the volume fraction. Other wall styles will still work, but they will result in the volume fraction being computed based on the box boundaries.

Since lubrication forces are dissipative, it is usually desirable to thermostat the system at a constant temperature. If Brownian motion (at a constant temperature) is desired, it can be set using the pair_style brownian command. These pair styles and the brownian style should use consistent parameters for $\mu$, flaglog, flagfld, cutinner, cutoff, flagHI and flagVF.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- cutinner (distance units)
- cutoff (distance units)

The two coefficients are optional. If neither is specified, the two cutoffs specified in the pair_style command are used. Otherwise both must be specified.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

---

### 20.139.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I \(!=\) J, the two cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

---

### 20.139.5 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Only spherical monodisperse particles are allowed for pair_style lubricate.

Only spherical particles are allowed for pair_style lubricate/poly.

These pair styles will not restart exactly when using the read_restart command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the read_restart command for more details.

---

### 20.139.6 Related commands

pair_coeff, pair_style lubricateU

---

### 20.139.7 Default

The default settings for the optional args are flagHI = 1 and flagVF = 1.

(Ball) Ball and Melrose, Physica A, 247, 444-472 (1997).

20.140 pair_style lubricateU command

20.141 pair_style lubricateU/poly command

20.141.1 Syntax

```
pair_style style mu flaglog cutinner cutoff gdot flagHI flagVF
```

- **style** = lubricateU or lubricateU/poly
- **mu** = dynamic viscosity (dynamic viscosity units)
- **flaglog** = 0/1 to exclude/include log terms in the lubrication approximation
- **cutinner** = inner cut off distance (distance units)
- **cutoff** = outer cutoff for interactions (distance units)
- **gdot** = shear rate (1/time units)
- **flagHI** (optional) = 0/1 to exclude/include 1/r hydrodynamic interactions
- **flagVF** (optional) = 0/1 to exclude/include volume fraction corrections in the long-range isotropic terms

20.141.2 Examples

(all assume radius = 1)

```
pair_style lubricateU 1.5 1 2.01 2.5 0.01 1 1
pair_coeff 1 1 2.05 2.8
pair_coeff * * 2.05 2.8
```

20.141.3 Description

Styles lubricateU and lubricateU/poly compute velocities and angular velocities for finite-size spherical particles such that the hydrodynamic interaction balances the force and torque due to all other types of interactions.

The interactions have 2 components. The first is Ball-Melrose lubrication terms via the formulas in (Ball and Melrose)

\[
W = -a_{sq}|(v_1 - v_2) \cdot nn|^2 - a_{sh}|(\omega_1 + \omega_2) \cdot (I - nn) - 2\Omega_N|^2 - \\
a_{pu}|(\omega_1 - \omega_2) \cdot (I - nn)|^2 - a_{tw}|(\omega_1 - \omega_2) \cdot nn|^2, \quad r < r_c
\]

\[
\Omega_N = n \times (v_1 - v_2)/r
\]

which represents the dissipation W between two nearby particles due to their relative velocities in the presence of a background solvent with viscosity mu. Note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity.

The Asq (squeeze) term is the strongest and is included as long as flagHI is set to 1 (default). It scales as 1/gap where gap is the separation between the surfaces of the 2 particles. The Ash (shear) and Apu (pump) terms are only included if flaglog is set to 1. They are the next strongest interactions, and the only other singular interaction, and scale as log(gap). Note that flaglog = 1 and flagHI = 0 is invalid, and will result in a warning message, after which flagHI will be set to 1. The Atw (twist) term is currently not included. It is typically a very small contribution to the lubrication forces.
The flagHI and flagVF settings are optional. Neither should be used, or both must be defined.

Cutinner sets the minimum center-to-center separation that will be used in calculations irrespective of the actual separation. Cutoff is the maximum center-to-center separation at which an interaction is computed. Using a cutoff less than 3 radii is recommended if flaglog is set to 1.

The other component is due to the Fast Lubrication Dynamics (FLD) approximation, described in (Kumar). The equation being solved to balance the forces and torques is

\[-R_{FU}(U - U^\infty) = -R_{FE}E^\infty - F_{rest}\]

where \(U\) represents the velocities and angular velocities of the particles, \(U^\infty\) represents the velocities and the angular velocities of the undisturbed fluid, and \(E^\infty\) represents the rate of strain tensor of the undisturbed fluid flow with viscosity \(\mu\). Again, note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity.

Volume fraction corrections to \(R_{FU}\) are included if flagVF is set to 1 (default).

\(F_{rest}\) represents the forces and torques due to all other types of interactions, e.g. Brownian, electrostatic etc. Note that this algorithm neglects the inertial terms, thereby removing the restriction of resolving the small interal time scale, which may not be of interest for colloidal particles. This pair style solves for the velocity such that the hydrodynamic force balances all other types of forces, thereby resulting in a net zero force (zero inertia limit). When defining this pair style, it must be defined last so that when this style is invoked all other types of forces have already been computed. For the same reason, it won’t work if additional non-pair styles are defined (such as bond or Kspace forces) as they are calculated in LAMMPS after the pairwise interactions have been computed.

Note: When using these styles, the these pair styles are designed to be used with implicit time integration and a correspondingly larger timestep. Thus either fix nve/noforce should be used for spherical particles defined via atom_style sphere or fix nve/asphere/noforce should be used for spherical particles defined via atom_style ellipsoid. This is because the velocity and angular momentum of each particle is set by the pair style, and should not be reset by the time integration fix.

Style lubricateU requires monodisperse spherical particles; style lubricateU/poly allows for polydisperse spherical particles.

If the suspension is sheared via the fix deform command then the pair style uses the shear rate to adjust the hydrodynamic interactions accordingly. Volume changes due to fix deform are accounted for when computing the volume fraction corrections to \(R_{FU}\).

When computing the volume fraction corrections to \(R_{FU}\), the presence of walls (whether moving or stationary) will affect the volume fraction available to colloidal particles. This is currently accounted for with the following types of walls: wall/lj93, wall/lj126, wall/colloid, and wall/harmonic. For these wall styles, the correct volume fraction will be used when walls do not coincide with the box boundary, as well as when walls move and thereby cause a change in the volume fraction. To use these wall styles with pair_style lubricateU or lubricateU/poly, the fld yes option must be specified in the fix wall command.

Since lubrication forces are dissipative, it is usually desirable to thermostat the system at a constant temperature. If Brownian motion (at a constant temperature) is desired, it can be set using the pair_style brownian command. These pair styles and the brownian style should use consistent parameters for mu, flaglog, flagfld, cutinner, cutoff, flagHI and flagVF.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- cutinner (distance units)
- cutoff (distance units)
The two coefficients are optional. If neither is specified, the two cutoffs specified in the pair_style command are used. Otherwise both must be specified.

### 20.141.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I ≠ J, the two cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

### 20.141.5 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Currently, these pair styles assume that all other types of forces/torques on the particles have been already been computed when it is invoked. This requires this style to be defined as the last of the pair styles, and that no fixes apply additional constraint forces. One exception is the fix wall/colloid commands, which has an “fld” option to apply their wall forces correctly.

Only spherical monodisperse particles are allowed for pair_style lubricateU.

Only spherical particles are allowed for pair_style lubricateU/poly.

For sheared suspensions, it is assumed that the shearing is done in the xy plane, with x being the velocity direction and y being the velocity-gradient direction. In this case, one must use fix deform with the same rate of shear (erate).

pair_coeff 1 1 1021760.3664 2120.317338 3.0 3.2
```

20.144.3 Description

The `lj/mdf`, `buck/mdf` and `lennard/mdf` compute the standard 12-6 Lennard-Jones and Buckingham potential with the addition of a taper function that ramps the energy and force smoothly to zero between an inner and outer cutoff.

\[ E_{\text{smooth}}(r) = E(r) \ast f(r) \]

The tapering, \( f(r) \), is done by using the Mei, Davenport, Fernando function \((Mei)\).

\[
\begin{align*}
  f(r) &= 1.0 \quad \text{for} \quad r < r_m \\
  f(r) &= (1 - x)^3 \ast (1 + 3x + 6x^2) \quad \text{for} \quad r_m < r < r_{\text{cut}} \\
  f(r) &= 0.0 \quad \text{for} \quad r \geq r_{\text{cut}}
\end{align*}
\]
where
\[ x = \frac{(r - r_m)}{(r_{cut} - r_m)} \]

Here \( r_m \) is the inner cutoff radius and \( r_{cut} \) is the outer cutoff radius.

For the \textit{lj/mdf} pair\_style, the potential energy, \( E(r) \), is the standard 12-6 Lennard-Jones written in the epsilon/sigma form:
\[
E(r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right]
\]

Either the first two or all of the following coefficients must be defined for each pair of atoms types via the pair\_coeff command as in the examples above, or in the data file read by the read\_data. The two cutoffs default to the global values and \( \epsilon \) and \( \sigma \) can also be determined by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- \( r_m \) (distance units)
- \( r_{cut} \) (distance units)

For the \textit{buck/mdf} pair\_style, the potential energy, \( E(r) \), is the standard Buckingham potential with three required coefficients. The two cutoffs can be omitted and default to the corresponding global values:
\[
E(r) = Ae^{(-r/\rho)} - \frac{C}{r^6}
\]

- \( A \) (energy units)
- \( \rho \) (distance units)
- \( C \) (energy-distance^6 units)
- \( r_m \) (distance units)
- \( r_{cut} \) (distance units)

For the \textit{lennard/mdf} pair\_style, the potential energy, \( E(r) \), is the standard 12-6 Lennard-Jones written in the A/B form:
\[
E(r) = \frac{A}{r^{12}} - \frac{B}{r^6}
\]

The following coefficients must be defined for each pair of atoms types via the pair\_coeff command as in the examples above, or in the data file read by the read\_data commands, or by mixing as described below. The two cutoffs default to their global values and must be either both given or both left out:

- \( A \) (energy-distance^12 units)
- \( B \) (energy-distance^6 units)
- \( r_m \) (distance units)
- \( r_{cut} \) (distance units)
20.144.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I ≠ J, the $\epsilon$ and $\sigma$ coefficients and cutoff distances for the lj/mdf pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details. The other two pair styles buck/mdf and lennard/mdf do not support mixing, so all IJ pairs of coefficients must be specified explicitly.

None of the lj/mdf, buck/mdf, or lennard/mdf pair styles supports the pair_modify shift option or long-range tail corrections to pressure and energy.

These styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

20.144.5 Restrictions

These pair styles can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

```
pair_style meam/spline
pair_coeff * * Ti.meam.spline Ti
pair_coeff * * Ti.meam.spline Ti Ti Ti
```

20.145.3 Description

The `meam/spline` style computes pairwise interactions for metals using a variant of modified embedded-atom method (MEAM) potentials (Lenosky). For a single species (“old-style”) MEAM, the total energy \( E \) is given by

\[
E = \sum_{i<j} \phi(r_{ij}) + \sum_i U(n_i)
\]

\[
n_i = \sum_j \rho(r_{ij}) + \sum_{j<k, j,k\neq i} f(r_{ij}) f(r_{ik}) g[\cos(\theta_{ijk})]
\]

where \( \rho_i \) is the density at atom I, \( \theta_{jik} \) is the angle between atoms J, I, and K centered on atom I. The five functions \( \phi, U, \rho, f, \) and \( g \) are represented by cubic splines.

The `meam/spline` style also supports a new style multicomponent modified embedded-atom method (MEAM) potential (Zhang), where the total energy \( E \) is given by

\[
E = \sum_{i<j} \phi_{ij}(r_{ij}) + \sum_i U_i(n_i)
\]

\[
n_i = \sum_j \rho_j(r_{ij}) + \sum_{j<k, j,k\neq i} f_j(r_{ij}) f_k(r_{ik}) g_{jk}[\cos(\theta_{jik})]
\]

where the five functions \( \phi, U, \rho, f, \) and \( g \) depend on the chemistry of the atoms in the interaction. In particular, if there are \( N \) different chemistries, there are \( N \) different \( U, \rho, \) and \( f \) functions, while there are \( N(N+1)/2 \) different \( \phi \) and \( g \) functions. The new style multicomponent MEAM potential files are indicated by the second line in the file starts with “meam/spline” followed by the number of elements and the name of each element.

The cutoffs and the coefficients for these spline functions are listed in a parameter file which is specified by the `pair_coeff` command. Parameter files for different elements are included in the “potentials” directory of the LAMMPS distribution and have a “.meam.spline” file suffix. All of these files are parameterized in terms of LAMMPS metal units.

Note that unlike for other potentials, cutoffs for spline-based MEAM potentials are not set in the pair_style or pair_coeff command; they are specified in the potential files themselves.

Unlike the EAM pair style, which retrieves the atomic mass from the potential file, the spline-based MEAM potentials do not include mass information; thus you need to use the `mass` command to specify it.

Only a single `pair_coeff` command is used with the `meam/spline` style which specifies a potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:

- filename
- \( N \) element names = mapping of spline-based MEAM elements to atom types

See the `pair_coeff` doc page for alternate ways to specify the path for the potential file.

As an example, imagine the Ti.meam.spline file has values for Ti (old style). If your LAMMPS simulation has 3 atoms types and they are all to be treated with this potentials, you would use the following pair_coeff command:
The first 2 arguments must be * * so as to span all LAMMPS atom types. The three Ti arguments map LAMMPS atom types 1,2,3 to the Ti element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a meam/spline potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials. The old-style potential maps any non-NULL species named on the command line to that single type.

An example with a two component spline (new style) is TiO.meam.spline, where the command

```
pair_coeff * * TiO.meam.spline Ti O
```

will map the first atom type to Ti and the second atom type to O. Note in this case that the species names need to match exactly with the names of the elements in the TiO.meam.spline file; otherwise an error will be raised. This behavior is different than the old style MEAM files.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.145.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify shift, table, and tail options.

The meam/spline pair style does not write its information to binary restart files, since it is stored in an external potential parameter file. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

The meam/spline pair style can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

### 20.145.5 Restrictions

This pair style requires the newton setting to be “on” for pair interactions.

This pair style is only enabled if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

20.146 pair_style meam/sw/spline command

20.146.1 Syntax

pair_style meam/sw/spline

20.146.2 Examples

pair_style meam/sw/spline
pair_coeff * * Ti.meam.sw.spline Ti
pair_coeff * * Ti.meam.sw.spline Ti Ti Ti

20.146.3 Description

The meam/sw/spline style computes pairwise interactions for metals using a variant of modified embedded-atom method (MEAM) potentials (Lenosky) with an additional Stillinger-Weber (SW) term (Stillinger) in the energy. This form of the potential was first proposed by Nicklas, Fellinger, and Park (Nicklas). We refer to it as MEAM+SW. The total energy $E$ is given by

$$E = E_{MEAM} + E_{SW}$$

$$E_{MEAM} = \sum_{IJ} \phi(r_{IJ}) + \sum_{I} U(\rho_{I})$$

$$E_{SW} = \sum_{I} \sum_{JK} F(r_{IJ}) F(r_{IK}) G(\cos(\theta_{JK}))$$

$$\rho_{I} = \sum_{J} \rho(r_{IJ}) + \sum_{JK} f(r_{IJ}) f(r_{IK}) g(\cos(\theta_{JK}))$$

where $\rho_{I}$ is the density at atom I, $\theta_{JK}$ is the angle between atoms J, I, and K centered on atom I. The seven functions $\phi$, $F$, $G$, $U$, $f$, $f$, and $g$ are represented by cubic splines.

The cutoffs and the coefficients for these spline functions are listed in a parameter file which is specified by the pair_coeff command. Parameter files for different elements are included in the “potentials” directory of the LAMMPS distribution and have a “.meam.sw.spline” file suffix. All of these files are parameterized in terms of LAMMPS metal units.
Note that unlike for other potentials, cutoffs for spline-based MEAM+SW potentials are not set in the pair_style or pair_coeff command; they are specified in the potential files themselves.

Unlike the EAM pair style, which retrieves the atomic mass from the potential file, the spline-based MEAM+SW potentials do not include mass information; thus you need to use the mass command to specify it.

Only a single pair_coeff command is used with the meam/sw/spline style which specifies a potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of spline-based MEAM+SW elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, imagine the Ti.meam.sw.spline file has values for Ti. If your LAMMPS simulation has 3 atoms types and they are all to be treated with this potential, you would use the following pair_coeff command:

```
pair_coeff * * Ti.meam.sw.spline Ti Ti Ti
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The three Ti arguments map LAMMPS atom types 1,2,3 to the Ti element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a meam/sw/spline potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

**Note:** The meam/sw/spline style currently supports only single-element MEAM+SW potentials. It may be extended for alloy systems in the future.

Example input scripts that use this pair style are provided in the examples/USER/misc/meam_sw_spline directory.

### 20.146. Mixing, shift, table, tail correction, restart, rRESPA info

The pair style does not support multiple element types or mixing. It has been designed for pure elements only.

This pair style does not support the pair_modify shift, table, and tail options.

The meam/sw/spline pair style does not write its information to binary restart files, since it is stored in an external potential parameter file. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

The meam/sw/spline pair style can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.
20.146.5 Restrictions

This pair style requires the newton setting to be “on” for pair interactions.

This pair style is only enabled if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

```

20.147.3 Description

**Note:** The behavior of the MEAM potential for alloy systems has changed as of November 2010; see description below of the mixture_ref_t parameter

Style *meam/c* computes pairwise interactions for a variety of materials using modified embedded-atom method (MEAM) potentials (*Baskes*). Conceptually, it is an extension to the original *EAM potentials* which adds angular forces. It is thus suitable for modeling metals and alloys with fcc, bcc, hcp and diamond cubic structures, as well as covalently bonded materials like silicon and carbon. Style *meam/c* is a translation of the (now obsolete) *meam* code from Fortran to C++. It is functionally equivalent to *meam* but more efficient, and thus *meam* has been removed from LAMMPS after the 12 December 2018 release.
In the MEAM formulation, the total energy \( E \) of a system of atoms is given by:

\[
E = \sum_i \left\{ F_i(\bar{\rho}_i) + \frac{1}{2} \sum_{i \neq j} \phi_{ij}(r_{ij}) \right\}
\]

where \( F \) is the embedding energy which is a function of the atomic electron density \( \rho \), and \( \phi \) is a pair potential interaction. The pair interaction is summed over all neighbors \( J \) of atom \( I \) within the cutoff distance. As with EAM, the multi-body nature of the MEAM potential is a result of the embedding energy term. Details of the computation of the embedding and pair energies, as implemented in LAMMPS, are given in (Gullet) and references therein.

The various parameters in the MEAM formulas are listed in two files which are specified by the pair_coeff command. These are ASCII text files in a format consistent with other MD codes that implement MEAM potentials, such as the serial DYNAMO code and Warp. Several MEAM potential files with parameters for different materials are included in the “potentials” directory of the LAMMPS distribution with a “.meam” suffix. All of these are parameterized in terms of LAMMPS metal units.

Note that unlike for other potentials, cutoffs for MEAM potentials are not set in the pair_style or pair_coeff command; they are specified in the MEAM potential files themselves.

Only a single pair_coeff command is used with the meam style which specifies two MEAM files and the element(s) to extract information for. The MEAM elements are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the second filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:

- MEAM library file
- Elem1, Elem2, ...
- MEAM parameter file
- \( N \) element names = mapping of MEAM elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential files.

As an example, the potentials/library.meam file has generic MEAM settings for a variety of elements. The potentials/SiC.meam file has specific parameter settings for a Si and C alloy system. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * library.meam Si C sic.meam Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first filename is the element library file. The list of elements following it extracts lines from the library file and assigns numeric indices to these elements. The second filename is the alloy parameter file, which refers to elements using the numeric indices assigned before. The arguments after the parameter file map LAMMPS atom types to elements, i.e. LAMMPS atom types 1,2,3 to the MEAM Si element. The final C argument maps LAMMPS atom type 4 to the MEAM C element.

If the second filename is specified as NULL, no parameter file is read, which simply means the generic parameters in the library file are used. Use of the NULL specification for the parameter file is discouraged for systems with more than a single element type (e.g. alloys), since the parameter file is expected to set element interaction terms that are not captured by the information in the library file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when a meam potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Note: If the second filename is NULL, the element names between the two filenames can appear in any order, e.g. “Si C” or “C Si” in the example above. However, if the second filename is not NULL (as in the example above), it contains settings that are Fortran-indexed for the elements that precede it. Thus you need to insure you list the
elements between the filenames in an order consistent with how the values in the second filename are indexed. See
details below on the syntax for settings in the second file.

The MEAM library file provided with LAMMPS has the name potentials/library.meam. It is the “meamf” file used by
other MD codes. Aside from blank and comment lines (start with #) which can appear anywhere, it is formatted as a
series of entries, each of which has 19 parameters and can span multiple lines:
elt, lat, z, ielement, atwt, alpha, b0, b1, b2, b3, alat, esub, asub, t0, t1, t2, t3, rozero, ibar

The “elt” and “lat” parameters are text strings, such as elt = Si or Cu and lat = dia or fcc. Because the library file is
used by Fortran MD codes, these strings may be enclosed in single quotes, but this is not required. The other numeric
parameters match values in the formulas above. The value of the “elt” string is what is used in the pair_coeff command
to identify which settings from the library file you wish to read in. There can be multiple entries in the library file with
the same “elt” value; LAMMPS reads the first matching entry it finds and ignores the rest.

Other parameters in the MEAM library file correspond to single-element potential parameters:

lat = lattice structure of reference configuration
z = number of nearest neighbors in the reference structure
ielement = atomic number
atwt = atomic weight
alat = lattice constant of reference structure
esub = energy per atom (eV) in the reference structure at equilibrium
asub = "A" parameter for MEAM (see e.g. (Baskes))

The alpha, b0, b1, b2, b3, t0, t1, t2, t3 parameters correspond to the standard MEAM parameters in the literature
(Baskes) (the b parameters are the standard beta parameters). Note that only parameters normalized to t0 = 1.0 are
supported. The rozero parameter is an element-dependent density scaling that weights the reference background
density (see e.g. equation 4.5 in (Gullet)) and is typically 1.0 for single-element systems. The ibar parameter selects
the form of the function G(Gamma) used to compute the electron density; options are

0 => G = sqrt(1+Gamma)
1 => G = exp(Gamma/2)
2 => not implemented
3 => G = 2/(1+exp(-Gamma))
4 => G = sqrt(1+Gamma)
-5 => G = +-sqrt(abs(1+Gamma))

If used, the MEAM parameter file contains settings that override or complement the library file settings. Examples of
such parameter files are in the potentials directory with a “.meam” suffix. Their format is the same as is read by other
Fortran MD codes. Aside from blank and comment lines (start with #) which can appear anywhere, each line has one
of the following forms. Each line can also have a trailing comment (starting with #) which is ignored.

keyword = value
keyword(I) = value
keyword(I,J) = value
keyword(I,J,K) = value

The indices I, J, K correspond to the elements selected from the MEAM library file numbered in the order of how
those elements were selected starting from 1. Thus for the example given before

pair_coeff * = library.meam Si C sic.meam Si Si Si C

an index of 1 would refer to Si and an index of 2 to C.

The recognized keywords for the parameter file are as follows:

rc = cutoff radius for cutoff function; default = 4.0
delr = length of smoothing distance for cutoff function; default = 0.1
rho0(I) = relative density for element I (overwrites value read from meamf file)
Ec(I,J) = cohesive energy of reference structure for I-J mixture
delta(I,J) = heat of formation for I-J alloy; if Ec_IJ is input as zero, then LAMMPS sets Ec_IJ = (Ec_II + Ec_JJ)/2 - delta_IJ
alpha(I,J) = alpha parameter for pair potential between I and J (can be computed from bulk modulus of reference structure
re(I,J) = equilibrium distance between I and J in the reference structure
Cmax(I,J,K) = Cmax screening parameter when I-J pair is screened by K (I<=J); default = 2.8
Cmin(I,J,K) = Cmin screening parameter when I-J pair is screened by K (I<=J); default = 2.0
lattice(I,J) = lattice structure of I-J reference structure:
    fcc = face centered cubic
    bcc = body centered cubic
    hcp = hexagonal close-packed
    dim = dimer
    dia = diamond (interlaced fcc for alloy)
    dia3= diamond structure with primary 1NN and secondary 3NN
→interaction
    b1 = rock salt (NaCl structure)
    c1l = MoSi2 structure
    l12 = Cu3Au structure (lower case L, followed by 12)
    b2 = CsCl structure (interpenetrating simple cubic)
    ch4 = methane-like structure, only for binary system
    lin = linear structure (180 degree angle)
    zig = zigzag structure with a uniform angle
    tri = H2O-like structure that has an angle
nn2(I,J) = turn on second-nearest neighbor MEAM formulation for I-J pair (see for example (Lee)).
    0 = second-nearest neighbor formulation off
    1 = second-nearest neighbor formulation on
    default = 0
attrac(I,J) = additional cubic attraction term in Rose energy I-J pair
→potential
    default = 0
repuls(I,J) = additional cubic repulsive term in Rose energy I-J pair
→potential
    default = 0
zbl(I,J) = blend the MEAM I-J pair potential with the ZBL potential for small atom separations (ZBL)
    default = 1
theta(I,J) = angle between three atoms in line, zigzag, and trimer reference
→structures in degrees
    default = 180
gsmooth_factor = factor determining the length of the G-function smoothing region; only significant for ibar=0 or ibar=4.
    99.0 = short smoothing region, sharp step
    0.5 = long smoothing region, smooth step
    default = 99.0
augt1 = integer flag for whether to augment t1 parameter by

20.147. pair_style meam/c command
3/5*t3 to account for old vs. new meam formulations;
0 = don't augment t1
1 = augment t1
default = 1

ialloy = integer flag to use alternative averaging rule for t
  for comparison with the DYNAMO MEAM code
  0 = standard averaging (matches ialloy=0 in DYNAMO)
  1 = alternative averaging (matches ialloy=1 in DYNAMO)
  2 = no averaging of t (use single-element values)
default = 0

mixture_ref_t = integer flag to use mixture average of t to compute the
  reference density for alloys, instead of the single-element
  values
  (see description and warning elsewhere in this doc page)
  0 = do not use mixture averaging for t in the reference
  density
  1 = use mixture averaging for t in the reference density
  default = 0

erose_form = integer value to select the form of the Rose energy function
  (see description below).
  default = 0

emb_lin_neg = integer value to select embedding function for negative
  densities
  0 = F(rho)=0
  1 = F(rho) = -asub*esub*rho (linear in rho, matches
  DYNAMO)
default = 0

bkgd_dyn = integer value to select background density formula
  0 = rho_bkgd = rho_ref_meam(a) (as in the reference
  structure)
  1 = rho_bkgd = rho0_meam(a)*Z_meam(a) (matches DYNAMO)
default = 0

Rc, delr, re are in distance units (Angstroms in the case of metal units). Ec and delta are in energy units (eV in the
case of metal units).

Each keyword represents a quantity which is either a scalar, vector, 2d array, or 3d array and must be specified with
the correct corresponding array syntax. The indices I,J,K each run from 1 to N where N is the number of MEAM
elements being used.

Thus these lines

| rho0(2) = 2.25 |
| alpha(1,2) = 4.37 |

set rho0 for the second element to the value 2.25 and set alpha for the alloy interaction between elements 1 and 2 to
4.37.

The augt1 parameter is related to modifications in the MEAM formulation of the partial electron density function. In
recent literature, an extra term is included in the expression for the third-order density in order to make the densities
orthogonal (see for example (Wang), equation 3d); this term is included in the MEAM implementation in lammps.
However, in earlier published work this term was not included when deriving parameters, including most of those
provided in the library.meam file included with lammps, and to account for this difference the parameter t1 must be
augmented by 3/5*t3. If augt1=1, the default, this augmentation is done automatically. When parameter values are fit
using the modified density function, as in more recent literature, augt1 should be set to 0.

The mixture_ref_t parameter is available to match results with those of previous versions of lammps (before January 2011). Newer versions of lammps, by default, use the single-element values of the t parameters to compute the background reference density. This is the proper way to compute these parameters. Earlier versions of lammps used an alloy mixture averaged value of t to compute the background reference density. Setting mixture_ref_t=1 gives the old behavior. WARNING: using mixture_ref_t=1 will give results that are demonstrably incorrect for second-neighbor MEAM, and non-standard for first-neighbor MEAM; this option is included only for matching with previous versions of lammps and should be avoided if possible.

The parameters attrac and repuls, along with the integer selection parameter erose_form, can be used to modify the Rose energy function used to compute the pair potential. This function gives the energy of the reference state as a function of interatomic spacing. The form of this function is:

\[
astar = \alpha \times (r/re - 1.0)
\]

if erose_form = 0: \( erose = -Ec \times (1+\astar+a3*(\astar^{3}))/r/re \times \exp(-\astar) \)

if erose_form = 1: \( erose = -Ec \times (1+\astar+(\text{attrac}-\text{repuls}/r) \times (\astar^{3})) \times \exp(-\astar) \)

if erose_form = 2: \( erose = -Ec \times (1+\astar+a3*(\astar^{3})) \times \exp(-\astar) \)

\( a3 = \text{repuls}, \astar < 0 \)
\( a3 = \text{attrac}, \astar \geq 0 \)

Most published MEAM parameter sets use the default values attrac=repulse=0. Setting repuls=attrac=delta corresponds to the form used in several recent published MEAM parameter sets, such as (Valone).

**Note:** The default form of the erose expression in LAMMPS was corrected in March 2009. The current version is correct, but may show different behavior compared with earlier versions of lammps with the attrac and/or repuls parameters are non-zero. To obtain the previous default form, use erose_form = 1 (this form does not seem to appear in the literature). An alternative form (see e.g. (Lee2)) is available using erose_form = 2.

---

**20.147.4 Mixing, shift, table, tail correction, restart, rRESPA info**

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a pair_coeff command with I != J arguments for this style.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.
20.147.5 Restrictions

The *meam/c* style is provided in the USER-MEAMC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

The maximum number of elements, that can be read from the MEAM library file, is determined at compile time. The default is 5. If you need support for more elements, you have to change the define for the constant ‘maxelt’ at the beginning of the file src/USER-MEAMC/meam.h and update/recompile LAMMPS. There is no limit on the number of atoms types.

```
pair_style mesocnt
pair_coeff * * 10_10.cnt
```
20.148.3 Description

Style mesocnt implements a mesoscopic potential for the interaction of carbon nanotubes (CNTs). In this potential, CNTs are modelled as chains of cylindrical segments in which each infinitesimal surface element interacts with all other CNT surface elements with the Lennard-Jones (LJ) term adopted from the airebo style. The interaction energy is then computed by integrating over the surfaces of all interacting CNTs.

The potential is based on interactions between one cylindrical segment and infinitely or semi-infinitely long CNTs as described in (Volkov1). Chains of segments are converted to these (semi-)infinite CNTs bases on an approximate chain approach outlined in (Volkov2). This allows to simplify the computation of the interactions significantly and reduces the computational times to the same order of magnitude as for regular bead spring models where beads interact with the standard pair_lj/cut potential.

In LAMMPS, cylindrical segments are represented by bonds. Each segment is defined by its two end points (“nodes”) which correspond to atoms in LAMMPS. For the exact functional form of the potential and implementation details, the reader is referred to the original papers (Volkov1) and (Volkov2).

The potential requires tabulated data provided in a single ASCII text file specified in the pair_coeff command. The first line of the file provides a time stamp and general information. The second line lists four integers giving the number of data points provided in the subsequent four data tables. The third line lists four floating point numbers: the CNT radius R, the LJ parameter sigma and two numerical parameters delta1 and delta2. These four parameters are given in Angstroms. This is followed by four data tables each separated by a single empty line. The first two tables have two columns and list the parameters uInfParallel and Gamma respectively. The last two tables have three columns giving data on a quadratic array and list the parameters Phi and uSemiParallel respectively. uInfParallel and uSemiParallel are given in eV/Angstrom, Phi is given in eV and Gamma is unitless.

Potential files for CNTs can be readily generated using the freely available code provided on

https://github.com/phankl/cntpot

Using the same approach, it should also be possible to generate potential files for other 1D systems such as boron nitride nanotubes.

Note: LAMMPS comes with one mesocnt style potential file where the default number of data points per table is 1001. This is sufficient for NVT simulations. For proper energy conservation, we recommend using a potential file where the resolution for Phi is at least 2001 data points.

Note: The mesocnt style requires CNTs to be represented as a chain of atoms connected by bonds. Atoms need to be numbered consecutively within one chain. Atoms belonging to different CNTs need to be assigned different molecule IDs.

A full summary of the method and LAMMPS implementation details is expected to soon become available in Computer Physics Communications.
20.148.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing.

This pair style does not support the pair_modify shift, table, and tail options.

The mesocnt pair style do not write their information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

20.148.5 Restrictions

This style is part of the USER-MESONT package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair potential requires the newton setting to be “on” for pair interactions.

20.152.3 Description

The `edpd` style computes the pairwise interactions and heat fluxes for eDPD particles following the formulations in (Li2014_JCP) and Li2015_CC. The time evolution of an eDPD particle is governed by the conservation of momentum and energy given by

\[
\frac{d^2 r_i}{dt^2} = \frac{dv_i}{dt} = F_i = \sum_{i \neq j} \left( F_{ij}^C + F_{ij}^D + F_{ij}^R \right)
\]

\[
C_e \frac{dT_i}{dt} = q_i = \sum_{i \neq j} \left( q_{ij}^C + q_{ij}^V + q_{ij}^R \right).
\]
where the three components of $F_i$ including the conservative force $F_{Cij}^i$, dissipative force $F_{Dij}^i$ and random force $F_{Rij}^i$ are expressed as

\[
F_{Cij}^i = \alpha_{ij} \omega_C(r_{ij}) \mathbf{e}_{ij}
\]
\[
F_{Dij}^i = -\gamma \omega_D(r_{ij})(\mathbf{e}_{ij} \cdot \mathbf{v}_{ij}) \mathbf{e}_{ij}
\]
\[
F_{Rij}^i = \sigma \omega_R(r_{ij}) \xi_{ij} \Delta t^{-1/2} \mathbf{e}_{ij}
\]
\[
\omega_C(r) = 1 - r/r_e
\]
\[
\alpha_{ij} = A \cdot k_B(T_i + T_j)/2
\]
\[
\omega_D(r) = \omega_D^2(r) = (1 - r/r_e)^{s_T}
\]
\[
\sigma_{ij}^2 = 4\gamma k_B T_i T_j / (T_i + T_j)
\]

in which the exponent of the weighting function $s$ can be defined as a temperature-dependent variable. The heat flux between particles accounting for the collisional heat flux $q_C^i$, viscous heat flux $q_V^i$, and random heat flux $q_R^i$ are given by

\[
q_C^i = \sum_{j \neq i} k_{ij} \omega_{CT}(r_{ij}) \left( \frac{1}{T_i} - \frac{1}{T_j} \right)
\]
\[
q_V^i = \frac{1}{2C_v} \sum_{j \neq i} \left\{ \omega_D(r_{ij}) \left[ \gamma_{ij} \left( \mathbf{e}_{ij} \cdot \mathbf{v}_{ij} \right)^2 - \frac{(\sigma_{ij})^2}{m} \right] - \sigma_{ij} \omega_R(r_{ij}) \left( \mathbf{e}_{ij} \cdot \mathbf{v}_{ij} \right) \xi_{ij} \right\}
\]
\[
q_R^i = \sum_{j \neq i} \beta_{ij} \omega_{RT}(r_{ij}) dt^{-1/2} \xi_{ij}
\]
\[
\omega_{CT}(r) = \omega_{RT}^2(r) = (1 - r/r_{ct})^{s_T}
\]
\[
k_{ij} = C_v^2 \kappa (T_i + T_j)^2/4k_B
\]
\[
\beta_{ij}^2 = 2k_B k_{ij}
\]

where the mesoscopic heat friction $\kappa$ is given by

\[
\kappa = \frac{315k_B \nu}{2\pi \rho C_v r_{ct}^5} \frac{1}{Pr},
\]

with $\nu$ being the kinematic viscosity. For more details, see Eq.(15) in (Li2014_JCP).

The following coefficients must be defined in eDPD system for each pair of atom types via the `pair_coeff` command as in the examples above.

- A (force units)
- $\gamma$ (force/velocity units)
- `power_f` (positive real)
- `cutoff` (distance units)
- `kappa` (thermal conductivity units)
- `power_T` (positive real)
- `cutoff_T` (distance units)
- `optional keyword = power or kappa`

The keyword `power` or `kappa` is optional. Both “power” and “kappa” require 4 parameters $c_1, c_2, c_3, c_4$ showing the temperature dependence of the exponent $s(T) = power_f(1 + c_1(T-1) + c_2(T-1)^2 + c_3(T-1)^3 + c_4(T-1)^4)$ and of the mesoscopic heat friction $s_T(T) = \kappa(1 + c_1(T-1) + c_2(T-1)^2 + c_3(T-1)^3 + c_4(T-1)^4)$. If the keyword `power` or `kappa` is not specified, the eDPD system will use constant `power_f` and $\kappa$, which is independent to temperature changes.
The `mdpd/rhosum` style computes the local particle mass density $\rho$ for mDPD particles by kernel function interpolation. The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above.

- `cutoff` (distance units)

The `mdpd` style computes the many-body interactions between mDPD particles following the formulations in (Li2013_POF). The dissipative and random forces are in the form same as the classical DPD, but the conservative force is local density dependent, which are given by

$$
F_C^{ij} = Aw_c(r_{ij})e_{ij} + B(\rho_i + \rho_j)w_d(r_{ij})e_{ij} \\
F_D^{ij} = -\gamma\omega_D(r_{ij})(e_{ij} \cdot \mathbf{v}_{ij})e_{ij} \\
F_R^{ij} = \sigma\omega_R(r_{ij})\xi_{ij}\Delta t^{-1/2}e_{ij}
$$

where the first term in $F_C$ with a negative coefficient $A < 0$ stands for an attractive force within an interaction range $r_c$, and the second term with $B > 0$ is the density-dependent repulsive force within an interaction range $r_d$.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above.

- `A` (force units)
- `B` (force units)
- `$\gamma$` (force/velocity units)
- `cutoff_c` (distance units)
- `cutoff_d` (distance units)

The `tdpd` style computes the pairwise interactions and chemical concentration fluxes for tDPD particles following the formulations in (Li2015_JCP). The time evolution of a tDPD particle is governed by the conservation of momentum and concentration given by

$$
\frac{d^2r_i}{dt^2} = \frac{dv_i}{dt} = F_i = \sum_{i \neq j}(F_C^{ij} + F_D^{ij} + F_R^{ij}) \\
\frac{dC_i}{dt} = Q_i = \sum_{i \neq j}(Q_D^{ij} + Q_R^{ij}) + Q_i^S
$$

where the three components of $F_i$ including the conservative force $F_C^{ij}$, dissipative force $F_D^{ij}$ and random force $F_R^{ij}$ are expressed as

$$
F_C^{ij} = A\omega_C(r_{ij})e_{ij} \\
F_D^{ij} = -\gamma\omega_D(r_{ij})(e_{ij} \cdot \mathbf{v}_{ij})e_{ij} \\
F_R^{ij} = \sigma\omega_R(r_{ij})\xi_{ij}\Delta t^{-1/2}e_{ij} \\
\omega_C(r) = 1 - r/r_c \\
\omega_D(r) = \omega_D^2(r) = (1 - r/r_c)^{power} \\
\sigma^2 = 2\gamma k_B T
$$
The concentration flux between two tDPD particles includes the Fickian flux $Q_{ij}^D$ and random flux $Q_{ij}^R$, which are given by

\[
Q_{ij}^D = -\kappa_{ij} w_{DC}(r_{ij}) (C_i - C_j)
\]
\[
Q_{ij}^R = \epsilon_{ij} (C_i + C_j) w_{RC}(r_{ij}) \xi_{ij}
\]
\[
w_{DC}(r_{ij}) = w_{RC}^2(r_{ij}) = (1 - r/r_{cc})^{\text{power}_{cc}}
\]
\[
\epsilon_{ij}^2 = m_s^2 \kappa_{ij} \rho
\]

where the parameters kappa and epsilon determine the strength of the Fickian and random fluxes. $m_s$ is the mass of a single solute molecule. In general, $m_s$ is much smaller than the mass of a tDPD particle $m$. For more details, see (Li2015_JCP).

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above.

- A (force units)
- $\gamma$ (force/velocity units)
- `power_f` (positive real)
- `cutoff` (distance units)
- `cutoff_CC` (distance units)
- $\kappa_i$ (diffusivity units)
- $\epsilon_i$ (diffusivity units)
- `power_cc_i` (positive real)

The last 3 values must be repeated Nspecies times, so that values for each of the Nspecies chemical species are specified, as indicated by the “I” suffix. In the first `pair_coeff` example above for `pair_style tdpd`, Nspecies = 1. In the second example, Nspecies = 2, so 3 additional coeffs are specified (for species 2).

### 20.152.4 Example scripts

There are example scripts for using all these pair styles in examples/USER/meso. The example for an eDPD simulation models heat conduction with source terms analog of periodic Poiseuille flow problem. The setup follows Fig.12 in (Li2014_JCP). The output of the short eDPD simulation (about 2 minutes on a single core) gives a temperature and density profiles as
The example for a mDPD simulation models the oscillations of a liquid droplet started from a liquid film. The mDPD parameters are adopted from (Li2013_POF). The short mDPD run (about 2 minutes on a single core) generates a particle trajectory which can be visualized as follows.

The first image is the initial state of the simulation. If you click it a GIF movie should play in your browser. The second image is the final state of the simulation.

The example for a tDPD simulation computes the effective diffusion coefficient of a tDPD system using a method analogous to the periodic Poiseuille flow. The tDPD system is specified with two chemical species, and the setup follows Fig.1 in (Li2015_JCP). The output of the short tDPD simulation (about one and a half minutes on a single core) gives the concentration profiles of the two chemical species as

20.152. pair_style tdpd command
20.152.5 Mixing, shift, table, tail correction, restart, rRESPA info

The styles edpd, mdpd, mdpd/rhosum and tdpd do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The styles edpd, mdpd, mdpd/rhosum and tdpd do not support the pair_modify shift, table, and tail options.

The styles edpd, mdpd, mdpd/rhosum and tdpd do not write information to binary restart files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

20.152.6 Restrictions

The pair styles edpd, mdpd, mdpd/rhosum and tdpd are part of the USER-MESODPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

none

20.153 pair_style mesont/tpm command

20.153.1 Syntax

```
pair_style mesont/tpm cut table_path BendingMode TPMType
```

- `cut` = the cutoff distance
- `table_path` = the path to the potential table
- `BendingMode` = the parameter defining the type of the bending potential for nanotubes: 0 - harmonic bending (Srivastava), 1 - anharmonic potential of bending and bending-buckling (Zhigilei1)
- `TPMType` = the parameter determining the type of the inter-tube interaction term: 0 - segment-segment approach, 1 - segment-chain approach (Zhigilei2, Zhigilei3)

The segment-segment approach is approximately 5 times slower than segment-chain approximation. The parameter `BendingMode` also affects the calculation of the inter-tube interaction term when `TPMType` = 1. In this case, when `BendingMode` = 1, each continuous chain of segments is additionally replaced by a number of sub-chains divided by bending buckling kinks.

20.153.2 Examples

```
pair_style mesont/tpm 30.0 MESONT-TABTP_10_10.xrs 0 0
```

20.153.3 Description

The tubular potential model (TPM) force field is designed for mesoscopic simulations of interacting flexible nanotubes. The force field is based on the mesoscopic computational model suggested in Ref. (Srivastava). In this model, each nanotube is represented by a chain of mesoscopic elements in the form of stretchable cylindrical segments, where each segment consists of multiple atoms. Each nanotube is divided into segments by a sequence of nodes placed on the nanotube centerline. This sequence of nodes determines the spatial position of the cylindrical segments and defines the configuration of the entire tube.

The potential force field that controls the dynamic behavior of a system of interacting nanotubes is given by the following equation defining the potential energy of the system:

\[ U = U_{str} + U_{bnd} + U_{vdW} \]

where \( U_{str} \) is the harmonic potential describing the stretching of nanotube (Srivastava), \( U_{bnd} \) is the potential for nanotube bending (Srivastava) and bending-buckling (Zhigilei1), and \( U_{vdW} \) is the potential describing van-der Waals interaction between nanotubes (Zhigilei2, Zhigilei3). The stretching energy, \( U_{str} \), is given by the sum of stretching energies of individual nanotube segments. The bending energy, \( U_{bnd} \), is given by the sum of bending energies in all internal nanotube nodes. The tube-tube interaction energy, \( U_{vdW} \), is calculated based on the tubular potential method suggested in Ref. (Zhigilei2). The tubular potential method is briefly described below.

The interaction between two straight nanotubes of arbitrary length and orientation is described by the approximate tubular potential developed in (Zhigilei3). This potential approximates the results of direct integration of carbon-carbon interatomic potential over the surfaces of the interacting nanotubes, with the force sources homogeneously distributed over the nanotube surfaces. The input data for calculation of tubular potentials are partially tabulated. For single-walled CNTs of arbitrary chirality, the tabulated potential data can be generated in the form of ASCII files TPMSSTP.xrs and TPMA.xrs by the stand-alone code TMDPotGen included in the tool directory of LAMMPS release. The potential provided with LAMMPS release, MESONT-TABTP_10_10.xrs, is tabulated for (10,10) nanotubes.
Calculations of the interaction between curved or bent nanotubes are performed on either segment-segment or segment-chain basis. In the first case, activated when parameter TPMTYPE is equal to 0, the tubular potential is calculated for each pair of interacting mesoscopic segments. In this case, however, small potential barriers for inter-tube sliding are introduced. While relatively small, these barriers are still larger than the ones that originate from the atomic-scale corrugation in atomistic modeling of inter-tube interaction. The latter are too weak to prevent room-temperature rearrangements of defect-free CNT, while the artificial mesoscopic barriers due to the segment-segment interaction can impede sliding of nanotubes with respect to each other and affect the kinetics of structural rearrangements in a system of nanotubes at moderate mesoscopic temperatures. In the second case, activated when parameter TPMTYPE is equal to 1, the inter-tube interaction term is calculated based on the segment-chain approach. In this case, for each NT segment, the list of its neighboring segments is divided into short continuous chains of segments belonging to individual nanotubes. For each pair of a segment and a chain, the curved chain is approximated by a straight equivalent nanotube based on the weighted approach suggested in Ref. (Zhigilei2). Finally, the interaction between the segment and straight equivalent chain is calculated based on the tubular potential. In this case, and in the absence of bending buckling (i.e., when parameter BendingMode is equal to 0), the tubular potential method ensures the absence of corrugation of the effective inter-tube interaction potential for curved nanotubes and eliminates any barriers for the inter-tube sliding. As a result, the tubular potential method can describe the spontaneous self-assembly of nanotubes into continuous networks of bundles (Zhigilei1, Zhigilei3).

The TMD force field has been used for generation of nanotube films, fibers, and vertically aligned forests of nanotubes. Mesoscopic dynamic simulations were used to prepare realistic structures of continuous networks of nanotube bundles and to study their structural and mechanical properties (Zhigilei1, Zhigilei3, Zhigilei4, Zhigilei5, Zhigilei6). With additional models for heat transfer, this force field was also used to study the thermal transport properties of carbon nanotube films (Zhigilei7, Zhigilei8, Zhigilei8). The methods for modeling of the mechanical energy dissipation into heat (energy exchange between the dynamic degrees of freedom of the mesoscopic model and the energy of atomic vibrations that are not explicitly represented in the model) (Zhigilei10) and mesoscopic description of covalent cross-links between nanotubes (Banna) have also been developed but are not included in this first release of the LAMMPS implementation of the force field. Further details can be found in references provided below.

The MESONT package also provides TMDGen code designed to generate initial samples composed of straight and dispersed nanotubes of given chirality and length at a given material density, which is available in tools directory. In the generated samples, nanotubes are distributed with random positions and orientations. Both periodic and free boundary conditions are available along each axis of the system of coordinates. All parameters in the sample files generated with TMDGen are given in metal units.

### 20.153.4 Restrictions

This pair style is a part of the USER-MSEONT package, and it is only enabled if LAMMPS is built with that package. See the Build package doc page for more information.

This pair potential requires use of mesont atomic style.

This pair potential requires the newton setting to be “on” for pair interactions.

The cutoff distance should be set to be at least $\max\left[2L, \sqrt{L^2/2 + (2R + T_{\text{cut}})^2}\right]$, where $L$ is the maximum segment length, $R$ is the maximum tube radius, and $T_{\text{cut}} = 10.2$ Å is the maximum distance between the surfaces of interacting segments. Because of the use of extended chain concept at CNT ends, the recommended cutoff is 3L.

The MESONT-TABTP_10_10.xrs potential file provided with LAMMPS (see the potentials directory) is parameterized for metal units. You can use the carbon nanotube mesoscopic force field with any LAMMPS units, but you would need to create your own TPMSSTP.xrs and TPMA.xrs potential files with coefficients listed in appropriate units, if your simulation does not use “metal” units.

The chirality parameters set during system generation must match the values specified during generation of the potential tables.

20.154.3 Description

Within DFT quantum mechanics, generalized pseudopotential theory (GPT) (Moriarty) provides a first-principles approach to multi-ion interatomic potentials in d-band transition metals, with a volume-dependent, real-space total-energy functional for the N-ion elemental bulk material in the form

\[ E_{\text{tot}}(R_1 \ldots R_N) = NE_{\text{vol}}(\Omega) + \frac{1}{2} \sum_{i,j} v_2(ij; \Omega) + \frac{1}{6} \sum_{i,j,k} v_3(ijk; \Omega) + \frac{1}{24} \sum_{i,j,k,l} v_4(ijkl; \Omega) \]
where the prime on each summation sign indicates the exclusion of all self-interaction terms from the summation. The leading volume term $E_{\text{vol}}$ as well as the two-ion central-force pair potential $v_{\text{2}}$ and the three- and four-ion angular-force potentials, $v_{\text{3}}$ and $v_{\text{4}}$, depend explicitly on the atomic volume Omega, but are structure independent and transferable to all bulk ion configurations, either ordered or disordered, and with or without the presence of point and line defects. The simplified model GPT or MGPT (Moriarty2, Moriarty3), which retains the form of $E_{\text{tot}}$ and permits more efficient large-scale atomistic simulations, derives from the GPT through a series of systematic approximations applied to $E_{\text{vol}}$ and the potentials $v_n$ that are valid for mid-period transition metals with nearly half-filled d bands.

Both analytic (Moriarty2) and matrix (Moriarty3) representations of MGPT have been developed. In the more general matrix representation, which can also be applied to f-band actinide metals and permits both canonical and non-canonical d/f bands, the multi-ion potentials are evaluated on the fly during a simulation through d- or f-state matrix multiplication, and the forces that move the ions are determined analytically. Fast matrix-MGPT algorithms have been developed independently by Glosli (Glosli, Moriarty3) and by Oppelstrup (Oppelstrup).

The mgpt pair style calculates forces, energies, and the total energy per atom, $E_{\text{tot}}/N$, using the Oppelstrup matrix-MGPT algorithm. Input potential and control data are entered through the pair_coeff command. Each material treated requires input parmin and potin potential files, as shown in the above examples, as well as specification by the user of the initial atomic volume Omega through pair_coeff. At the beginning of a time step in any simulation, the total volume of the simulation cell $V$ should always be equal to $\Omega^N$, where $N$ is the number of metal ions present, taking into account the presence of any vacancies and/or interstitials in the case of a solid. In a constant-volume simulation, which is the normal mode of operation for the mgpt pair style, Omega, $V$ and $N$ all remain constant throughout the simulation and thus are equal to their initial values. In a constant-stress simulation, the cell volume $V$ will change (slowly) as the simulation proceeds. After each time step, the atomic volume should be updated by the code as $\Omega = V/N$. In addition, the volume term $E_{\text{vol}}$ and the potentials $v_{\text{2}}$, $v_{\text{3}}$ and $v_{\text{4}}$ have to be removed at the end of the time step, and then respecified at the new value of Omega. In all simulations, Omega must remain within the defined volume range for $E_{\text{vol}}$ and the potentials for the given material.

The default option volpress yes in the pair_coeff command includes all volume derivatives of $E_{\text{tot}}$ required to calculate the stress tensor and pressure correctly. The option volpress no disregards the pressure contribution resulting from the volume term $E_{\text{vol}}$, and can be used for testing and analysis purposes. The additional optional variable nbody controls the specific terms in $E_{\text{tot}}$ that are calculated. The default option and the normal option for mid-period transition and actinide metals is nbody 1234 for which all four terms in $E_{\text{tot}}$ are retained. The option nbody 12, for example, retains only the volume term and the two-ion pair potential term and can be used for GPT series-end transition metals that can be well described without $v_{\text{3}}$ and $v_{\text{4}}$. The nbody option can also be used to test or analyze the contribution of any of the four terms in $E_{\text{tot}}$ to a given calculated property.

The mgpt pair style makes extensive use of matrix algebra and includes optimized kernels for the BlueGene/Q architecture and the Intel/AMD (x86) architectures. When compiled with the appropriate compiler and compiler switches (-msse3 on x86, and using the IBM XL compiler on BG/Q), these optimized routines are used automatically. For BG/Q machines, building with the default Makefile for that architecture (e.g., “make bgq”) should enable the optimized algebra routines. For x-86 machines, there is a provided Makefile.mgptfast which enables the fast algebra routines, i.e. build LAMMPS with “make mgptfast”. The user will be informed in the output files of the matrix kernels in use. To further improve speed, on x86 the option precision single can be added to the pair_coeff command line, which improves speed (up to a factor of two) at the cost of doing matrix calculations with 7 digit precision instead of the default 16. For consistency the default option can be specified explicitly by the option precision double.

All remaining potential and control data are contained with the parmin and potin files, including cutoffs, atomic mass, and other basic MGPT variables. Specific MGPT potential data for the transition metals tantalum (Ta4 and Ta6.8x potentials), molybdenum (Mo5.2 potentials), and vanadium (V6.1 potentials) are contained in the LAMMPS potentials directory. The stored files are, respectively, Ta4.mgpt.parmin, Ta4.mgpt.potin, Ta6.8x.mgpt.parmin, Ta6.8x.mgpt.potin, Mo5.2.mgpt.parmin, Mo5.2.mgpt.potin, V6.1.mgpt.parmin, and V6.1.mgpt.potin. Useful corresponding informational “README” files on the Ta4, Ta6.8x, Mo5.2 and V6.1 potentials are also included in the potentials directory. These latter files indicate the volume mesh and range for each potential and give appropriate references for the potentials. It is expected that MGPT potentials for additional materials will be added over time.

Useful example MGPT scripts are given in the examples/USER/mgpt directory. These scripts show the necessary steps to perform constant-volume calculations and simulations. It is strongly recommended that the user work through and
understand these examples before proceeding to more complex simulations.

**Note:** For good performance, LAMMPS should be built with the compiler flags “-O3 -msse3 -funroll-loops” when including this pair style. The src/MAKE/OPTIONS/Makefile.mgptfast is an example machine Makefile with these options included as part of a standard MPI build. Note that it as provided, it will build with whatever low-level compiler (g++, icc, etc) is the default for your MPI installation.

---

**20.154.4 Mixing, shift, table, tail correction, restart, rRESPA info**

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

---

**20.154.5 Restrictions**

This pair style is part of the USER-MGPT package and is only enabled if LAMMPS is built with that package. See the Build package doc page for more info.

The MGPT potentials require the `newtion` setting to be “on” for pair style interactions.

The stored parmin and potin potential files provided with LAMMPS in the “potentials” directory are written in Rydberg atomic units, with energies in Rydbergs and distances in Bohr radii. The `mgpt` pair style converts Rydbergs to Hartrees to make the potential files compatible with LAMMPS electron units.

The form of E_tot used in the `mgpt` pair style is only appropriate for elemental bulk solids and liquids. This includes solids with point and extended defects such as vacancies, interstitials, grain boundaries and dislocations. Alloys and free surfaces, however, require significant modifications, which are not included in the `mgpt` pair style. Likewise, the `hybrid` pair style is not allowed, where MGPT would be used for some atoms but not for others.

Electron-thermal effects are not included in the standard MGPT potentials provided in the “potentials” directory, where the potentials have been constructed at zero electron temperature. Physically, electron-thermal effects may be important in 3d (e.g., V) and 4d (e.g., Mo) transition metals at high temperatures near melt and above. It is expected that temperature-dependent-MGPT potentials for such cases will be added over time.

---

**20.154.6 Related commands**

`pair_coeff`
20.154.7 Default

The options defaults for the pair_coeff command are volpress yes, nbody 1234, and precision double.

20.155 pair_style mie/cut command

Accelerator Variants: mie/cut/gpu

20.155.1 Syntax

```
pair_style mie/cut cutoff

• cutoff = global cutoff for mie/cut interactions (distance units)
```

20.155.2 Examples

```
pair_style mie/cut 10.0
pair_coeff 1 1 0.72 3.40 23.00 6.66
pair_coeff 2 2 0.30 3.55 12.65 6.00
pair_coeff 1 2 0.46 3.32 16.90 6.31
```

20.155.3 Description

The mie/cut style computes the Mie potential, given by

\[ E = C \epsilon \left[ \left( \frac{\sigma}{r} \right)^{\gamma_{rep}} - \left( \frac{\sigma}{r} \right)^{\gamma_{att}} \right] \quad r < r_c \]

Rc is the cutoff and C is a function that depends on the repulsive and attractive exponents, given by:

\[ C = \left( \frac{\gamma_{rep}}{\gamma_{rep} - \gamma_{att}} \right) \left( \frac{\sigma_{rep}}{\gamma_{att}} \right)^{\gamma_{att}} \]

Note that for 12/6 exponents, C is equal to 4 and the formula is the same as the standard Lennard-Jones potential.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

• epsilon (energy units)
• sigma (distance units)
• gammaR
• gammaA
• cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used.

20.155.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, the epsilon and sigma coefficients and cutoff distance for all of the mie/cut pair styles can be mixed. If not explicitly defined, both the repulsive and attractive gamma exponents for different atoms will be calculated following the same mixing rule defined for distances. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

This pair style supports the pair_modify tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the run_style command for details.

20.155.5 Restrictions

(Mie) G. Mie, Ann Phys, 316, 657 (1903).

20.156 pair_style mliap command

20.156.1 Syntax

```
pair_style mliap ... keyword values ...
```

- two keyword/value pairs must be appended
- keyword = model or descriptor

```
model values = style filename
  style = linear or quadratic
  filename = name of file containing model definitions

descriptor values = style filename
  style = sna
  filename = name of file containing descriptor definitions
```

20.156.2 Examples

```
pair_style mliap model linear InP.mliap.model descriptor sna InP.mliap.descriptor
pair_style mliap model quadratic W.mliap.model descriptor sna W.mliap.descriptor
pair_coeff * * In P
```

20.156.3 Description

Pair style *mliap* provides a general interface to families of machine-learning interatomic potentials. It allows separate definitions of the interatomic potential functional form (*model*) and the geometric quantities that characterize the atomic positions (*descriptor*). By defining *model* and *descriptor* separately, it is possible to use many different models with a given descriptor, or many different descriptors with a given model. Currently, the pair_style supports just two models, *linear* and *quadratic*, and one descriptor, *sna*, the SNAP descriptor used by pair_style snap, including the linear, quadratic, and chem variants. Work is currently underway to extend the interface to handle neural network energy models, and it is also straightforward to add new descriptor styles. In order to train a model, it is useful to know the gradient or derivative of energy, force, and stress w.r.t. model parameters. This information can be accessed using the related *compute mliap* command.

The pair_style *mliap* command must be followed by two keywords *model* and *descriptor* in either order. A single pair_coeff command is also required. The first 2 arguments must be ** so as to span all LAMMPS atom types. This is followed by a list of N arguments that specify the mapping of MLIAP element names to LAMMPS atom types, where N is the number of LAMMPS atom types.

The *model* keyword is followed by a model style, currently limited to either *linear* or *quadratic*. In both cases, this is followed by a single argument specifying the model filename containing the parameters for a set of elements. The model filename usually ends in the _mliap.model_ extension. It may contain parameters for many elements. The only requirement is that it contain at least those element names appearing in the pair_coeff command.

The top of the model file can contain any number of blank and comment lines (start with #), but follows a strict format after that. The first non-blank non-comment line must contain two integers:

- nelems = Number of elements
- nparams = Number of parameters

This is followed by one block for each of the nelem elements. Each block consists of nparams parameters, one per line. Note that this format is similar, but not identical to that used for the pair_style snap coefficient file. Specifically, the line containing the element weight and radius is omitted, since these are handled by the descriptor.
The *descriptor* keyword is followed by a descriptor style, and additional arguments. Currently the only descriptor style is *sna*, indicating the bispectrum component descriptors used by the Spectral Neighbor Analysis Potential (SNAP) potentials of *pair_style snap*. A single additional argument specifies the descriptor filename containing the parameters and setting used by the SNAP descriptor. The descriptor filename usually ends in the .mliap.descriptor extension.

The SNAP descriptor file closely follows the format of the *pair_style snap* parameter file. The file can contain blank and comment lines (start with #) anywhere. Each non-blank non-comment line must contain one keyword/value pair. The required keywords are *rcutfac* and *twojmax*. There are many optional keywords that are described on the *pair_style snap* doc page. In addition, the SNAP descriptor file must contain the *nelems*, *elems*, *radelems*, and *welems* keywords. The *nelems* keyword specifies the number of elements provided in the other three keywords. The *elems* keyword is followed by a list of *nelems* element names that must include the element names appearing in the *pair_coeff* command, but can contain other names too. Similarly, the *radelems* and *welems* keywords are followed by lists of *nelems* numbers giving the element radius and element weight of each element. Obviously, the order in which the elements are listed must be consistent for all three keywords.

See the *pair_coeff* doc page for alternate ways to specify the path for these *model* and *descriptor* files.

### 20.156.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a *pair_coeff* command with I != J arguments for this style.

This pair style does not support the *pair_modify* shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 20.156.5 Restrictions

This style is part of the MLIAP package. It is only enabled if LAMMPS was built with that package. In addition, building LAMMPS with the MLIAP package requires building LAMMPS with the SNAP package. See the *Build package* doc page for more info.

### 20.156.6 Related commands

*pair_style snap*, *compute mliap*

### 20.156.7 Default

none
20.157 pair_style mm3/switch3/coulgauss/long command

20.157.1 Syntax

```
pair_style style args
```

- `style = mm3/switch3/coulgauss/long`
- `args = list of arguments for a particular style`

`mm3/switch3/coulgauss/long` args = cutoff (cutoff2) width
- `cutoff` = global cutoff for MM3 (and Coulombic if only 1 arg) (distance units)
- `cutoff2` = global cutoff for Coulombic (optional) (distance units)
- `width` = width parameter of the smoothing function (distance units)

20.157.2 Examples

```
pair_style mm3/switch3/coulgauss/long 12.0 3.0
pair_coeff 1 0.2 2.5 1.2

pair_style mm3/switch3/coulgauss/long 12.0 10.0 3.0
pair_coeff 1 0.2 2.5 1.2
```

20.157.3 Description

The `mm3/switch3/coulgauss/long` style evaluates the MM3 vdW potential (Allinger)

\[
E = \epsilon_{ij} \left[ -2.25 \left( \frac{r_{v,ij}}{r_{ij}} \right)^6 + 1.84(10)^5 \exp \left[ -12.0r_{ij}/r_{v,ij} \right] \right] S_3(r_{ij})
\]

\[
r_{v,ij} = r_{v,i} + r_{v,j}
\]

\[
\epsilon_{ij} = \sqrt{\epsilon_i \epsilon_j}
\]

, which goes smoothly to zero at the cutoff \( r_c \) as defined by the switching function

\[
S_3(r) = \begin{cases} 
1 & \text{if } r < r_c - w \\
3x^2 - 2x^3 & \text{if } r < r_c \text{ with } x = \frac{r - r_c}{w} \\
0 & \text{if } r \geq r_c
\end{cases}
\]

where \( w \) is the width defined in the arguments. This potential is combined with Coulomb interaction between Gaussian charge densities:

\[
E = \frac{q_i q_j \text{erf} \left( \frac{r}{\sqrt{\gamma_1^2 + \gamma_2^2}} \right)}{cr_{ij}}
\]

where \( q_i \) and \( q_j \) are the charges on the 2 atoms, epsilon is the dielectric constant which can be set by the dielectric command, \( \gamma_i \) and \( \gamma_j \) are the widths of the Gaussian charge distribution and erf() is the error-function. This style has to be used in conjunction with the kspace_style command.

If one cutoff is specified it is used for both the vdW and Coulomb terms. If two cutoffs are specified, the first is used as the cutoff for the vdW terms, and the second is the cutoff for the Coulombic term.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:
• \( \epsilon \) (energy)
• \( r_v \) (distance)
• \( \gamma \) (distance)

20.157.4 Mixing, shift, table, tail correction, restart, rRESPA info

Mixing rules are fixed for this style as defined above.
Shifting the potential energy is not necessary because the switching function ensures that the potential is zero at the cut-off.

20.157.5 Restrictions

These styles are part of the USER-YAFF package. They are only enabled if LAMMPS was built with that package.
See the Build package doc page for more info.

20.157.6 Related commands

pair_coeff

20.157.7 Default

20.158 pair_style momb command

20.158.1 Syntax

\texttt{pair\_style momb cutoff s6 d}

• cutoff = global cutoff (distance units)
• s6 = global scaling factor of the exchange-correlation functional used (unitless)
• d = damping scaling factor of Grimme’s method (unitless)

20.158.2 Examples

\texttt{pair\_style momb 12.0 0.75 20.0}
\texttt{pair\_style hybrid/overlay eam/fs lj/charmm/coul/long 10.0 12.0 momb 12.0 0.75 20.0, --morse 5.5}
\texttt{pair\_coeff 1 2 momb 0.0 1.0 1.0 10.2847 2.361}
20.158.3 Description

Style *momb* computes pairwise van der Waals (vdW) and short-range interactions using the Morse potential and (Grimme) method implemented in the Many-Body Metal-Organic (MOMB) force field described comprehensively in (Fichthorn) and (Zhou). Grimme’s method is widely used to correct for dispersion in density functional theory calculations.

\[
E = D_0 \left[ \exp^{-2\alpha (r-r_0)} - 2 \exp^{-\alpha (r-r_0)} \right] - s_6 \frac{C_6}{r_0^6} f_{\text{damp}}(r, R_r) \\
\]

\[
f_{\text{damp}}(r, R_r) = \frac{1}{1 + \exp\left(-d(r/R_r - 1)\right)}
\]

For the *momb* pair style, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data as described below:

- \(D_0\) (energy units)
- \(\alpha\) (1/distance units)
- \(r_0\) (distance units)
- \(C_6\) (energy*distance^6 units)
- \(R_r\) (distance units, typically sum of atomic vdW radii)

20.158.4 Restrictions

This style is part of the USER-MISC package. It is only enabled if LAMMPS is built with that package. See the Build package doc page on for more info.

20.158.5 Related commands

pair_coeff, pair_style morse

20.158.6 Default

20.159 pair_style morse command

Accelerator Variants: morse/gpu, morse/omp, morse/opt, morse/kk
20.160  pair_style morse/smooth/linear command

Accelerator Variants: morse/smooth/linear/omp

20.160.1 Syntax

```
pair_style  style  args
```

- style = morse or morse/smooth/linear or morse/soft
- args = list of arguments for a particular style

```
morse  args  =  cutoff
  cutoff  =  global  cutoff  for  Morse  interactions  (distance  units)
morse/smooth/linear  args  =  cutoff
  cutoff  =  global  cutoff  for  Morse  interactions  (distance  units)
```

20.160.2 Examples

```
pair_style  morse  2.5
pair_style  morse/smooth/linear  2.5
pair_coeff  * *  100.0  2.0  1.5
pair_coeff  1  1  100.0  2.0  1.5  3.0
```

20.160.3 Description

Style morse computes pairwise interactions with the formula

\[
E = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c
\]

\(r_c\) is the cutoff.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- \(D_0\) (energy units)
- \(\alpha\) (1/distance units)
- \(r_0\) (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global morse cutoff is used.

The morse/smooth/linear variant is similar to the lj/smooth/linear variant in that it adds to the potential a shift and a linear term so that both, potential energy and force, go to zero at the cut-off:

\[
\phi (r) = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c
\]

\[
E (r) = \phi (r) - \phi (r_c) - (r - r_c) \left. \frac{d\phi}{dr} \right|_{r=r_c} \quad r < R_c
\]

The syntax of the pair_style and pair_coeff commands are the same for the morse and morse/smooth/linear styles.
A version of the *morse* style with a soft core, *morse/soft*, suitable for use in free energy calculations, is part of the USER-FEP package and is documented with the *pair_style */soft* styles. The version with soft core is only available if LAMMPS was built with that package. See the *Build package* doc page for more info.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* command-line switch when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

### 20.160.4 Mixing, shift, table, tail correction, restart, rRESPA info

None of these pair styles support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

All of these pair styles support the *pair_modify* shift option for the energy of the pair interaction.

The *pair_modify* table options is not relevant for the Morse pair styles.

None of these pair styles support the *pair_modify* tail option for adding long-range tail corrections to energy and pressure.

All of these pair styles write their information to *binary restart files*, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

### 20.160.5 Restrictions

The *morse/smooth/linear* pair style is only enabled if LAMMPS was built with the USER-MISC package. See the *Build package* doc page for more info.

### 20.160.6 Related commands

*pair_coeff*, *pair_style */soft*
20.160.7 Default

none

20.161 pair_style multi/lucy command

20.161.1 Syntax

```
pair_style multi/lucy style N keyword ...
```

- style = lookup or linear = method of interpolation
- N = use N values in lookup, linear tables

20.161.2 Examples

```
pair_style multi/lucy linear 1000
pair_coeff * * multibody.table ENTRY1 7.0
```

20.161.3 Description

Style multi/lucy computes a density-dependent force following from the many-body form described in (Moore) and (Warren) as

\[
F_{DD}(\rho_i, \rho_j, r_{ij}) = \frac{1}{2} \omega_{DD}(r_{ij}) \left[ A(\rho_i) + A(\rho_j) \right] e_{ij}
\]

which consists of a density-dependent function, \(A(\rho)\), and a radial-dependent weight function, \(\omega_{DD}(r_{ij})\). The radial-dependent weight function, \(\omega_{DD}(r_{ij})\), is taken as the Lucy function:

\[
\omega_{DD}(r_{ij}) = \left(1 + \frac{3r_{ij}}{r_{cut}}\right) \left(1 + \frac{r_{ij}}{r_{cut}}\right)^3
\]

The density-dependent energy for a given particle is given by:

\[
u_{DD}(\rho_i) = \frac{\pi r_{cut}^4}{84} \int_{\rho_0}^{\rho_i} A(\rho') d\rho'
\]

See the supporting information of (Brennan) or the publication by (Moore) for more details on the functional form.

An interpolation table is used to evaluate the density-dependent energy (\(\int A(\rho') d\rho'\)) and force (\(A(\rho')\)). Note that the pre-factor to the energy is computed after the interpolation, thus the \(\int A(\rho') d\rho'\) will have units of energy / length^4.

The interpolation table is created as a pre-computation by fitting cubic splines to the file values and interpolating the density-dependent energy and force as needed for each pair of particles separated by a distance \(R\). The interpolation is done in one of 2 styles: lookup and linear.

For the lookup style, the density is used to find the nearest table entry, which is the density-dependent energy and force.

For the linear style, the density is used to find the 2 surrounding table values from which the density-dependent energy and force are computed by linear interpolation.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above.
• filename
• keyword
• cutoff (distance units)

The filename specifies a file containing the tabulated density-dependent energy and force. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

# Density-dependent function (one or more comment or blank lines)

DD-FUNCTION (keyword is first text on line)
N 500 R 1.0 10.0 (N, R, RSQ parameters)
(blank)
1 1.0 25.5 102.34 (index, density, energy/r^4, force)
2 1.02 23.4 98.5
...
500 10.0 0.001 0.003

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the pair_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the pair_style multi/lucy command. Let Ntable = N in the pair_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate the density-dependent energy and force at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing the density-dependent energy and force. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile, and use the “RSQ” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in density uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values rlo and rhi. If specified, the density associated with each density-dependent energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The density values in the table file are ignored in this case. For “R”, distances uniformly spaced between rlo and rhi are computed; for “RSQ”, squared distances uniformly spaced between rlo*rlo and rhi*rhi are computed.

Note: If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the density value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning density-dependent energy and force values to a different density, which is probably not what you want. LAMMPS will warn if this is occurring.
Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in density units), the third value is the density-dependent function value (in energy units / length^4), and the fourth is the force (in force units). The density values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

### 20.161.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

The `pair_modify shift, table, and tail` options are not relevant for this pair style.

This pair style writes the settings for the “pair_style multi/lucy” command to binary restart files, so a pair_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, `pair_coeff` commands do need to be specified in the restart input script.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner, middle, outer` keywords.

### 20.161.5 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

### 20.161.6 Related commands

`pair_coeff`

### 20.161.7 Default

`none`

### 20.162 pair_style multi/lucy/rx command

Accelerator Variants: `multi/lucy/rx/kk`
20.162.1 Syntax

```
pair_style multi/lucy/rx style N keyword ...
```

- style = lookup or linear = method of interpolation
- N = use N values in lookup, linear tables
- weighting = fractional or molecular (optional)

20.162.2 Examples

```
pair_style multi/lucy/rx linear 1000
pair_style multi/lucy/rx linear 1000 fractional
pair_style multi/lucy/rx linear 1000 molecular
pair_coeff * * multibody.table ENTRY1 h2o h2o 7.0
pair_coeff * * multibody.table ENTRY1 h2o 1fluid 7.0
```

20.162.3 Description

Style `multi/lucy/rx` is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of \( m \) species whose reaction rate kinetics are determined from a set of \( n \) reaction rate equations through the `fix rx` command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. Style `multi/lucy/rx` computes the site-site density-dependent force following from the many-body form described in (Moore) and (Warren) as

\[
F_{DD}^i(\rho_i, \rho_j, r_{ij}) = \frac{1}{2} \omega_{DD}(r_{ij}) \left[ A(\rho_i) + A(\rho_j) \right] e_{ij}
\]

which consists of a density-dependent function, \( A(\rho) \), and a radial-dependent weight function, \( \omega_{DD}(r_{ij}) \). The radial-dependent weight function, \( \omega_{DD}(r_{ij}) \), is taken as the Lucy function:

\[
\omega_{DD}(r_{ij}) = \left( 1 + \frac{3r_{ij}}{r_{cut}} \right) \left( 1 + \frac{r_{ij}}{r_{cut}} \right)^3
\]

The density-dependent energy for a given particle is given by:

\[
u_{DD}^i(\rho_i) = \frac{\pi r_{cut}^4}{8} \int_{\rho_0}^{\rho_i} A(\rho') d\rho'
\]

See the supporting information of (Brennan) or the publication by (Moore) for more details on the functional form.

An interpolation table is used to evaluate the density-dependent energy (\( \int A(\rho') d\rho' \)) and force (\( A(\rho') \)). Note that the pre-factor to the energy is computed after the interpolation, thus the \( \int A(\rho') d\rho' \) will have units of energy / length^4.

The interpolation table is created as a pre-computation by fitting cubic splines to the file values and interpolating the density-dependent energy and force at each of \( N \) densities. During a simulation, the tables are used to interpolate the density-dependent energy and force as needed for each pair of particles separated by a distance \( R \). The interpolation is done in one of 2 styles: `lookup` and `linear`.

For the `lookup` style, the density is used to find the nearest table entry, which is the density-dependent energy and force.

For the `linear` style, the density is used to find the 2 surrounding table values from which the density-dependent energy and force are computed by linear interpolation.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above.
The filename specifies a file containing the tabulated density-dependent energy and force. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The species tags define the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the fix rx command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the fractional or molecular weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

# Density-dependent function (one or more comment or blank lines)

DD-FUNCTION (keyword is first text on line)
N 500 R 1.0 10.0 (N, R, RSQ parameters)
1 1.0 25.5 102.34 (index, density, energy/r^4, force)
2 1.02 23.4 98.5
...
500 10.0 0.001 0.003

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the pair_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the pair_style multi/lucy/rx command. Let Ntable = N in the pair_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate the density-dependent energy and force at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing the density-dependent energy and force. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile, and use the “RSQ” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” does not appear, then the distances in each line of the table are used as is to perform spline interpolation. In this case, the table values can be spaced in density uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values rlo and rhi. If specified, the density associated with each density-dependent energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The density values in the table file are ignored in this case.
“R”, distances uniformly spaced between \( rlo \) and \( rhi \) are computed; for “RSQ”, squared distances uniformly spaced between \( rlo*rlo \) and \( rhi*rhi \) are computed.

**Note:** If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the density value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning density-dependent energy and force values to a different density, which is probably not what you want. LAMMPS will warn if this is occurring.

Following a blank line, the next \( N \) lines list the tabulated values. On each line, the first value is the index from 1 to \( N \), the second value is \( r \) (in density units), the third value is the density-dependent function value (in energy units / length\(^4\)), and the fourth is the force (in force units). The density values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

**20.162.4 Mixing, shift, table, tail correction, restart, rRESPA info**

This pair style does not support mixing. Thus, coefficients for all \( I,J \) pairs must be specified explicitly.

The `pair_modify` shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair_style multi/lucy/rx” command to binary restart files, so a pair_style command does not need to be specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, pair_coeff commands do need to be specified in the restart input script.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
20.162.5 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.162.6 Related commands

pair_coeff

20.162.7 Default

fractional weighting

20.163 pair_style nb3b/harmonic command

20.163.1 Syntax

```plaintext
pair_style nb3b/harmonic
```

20.163.2 Examples

```plaintext
pair_style nb3b/harmonic
pair_coeff * * MgOH.nb3bharmonic Mg O H
```

20.163.3 Description

This pair style computes a non-bonded 3-body harmonic potential for the energy $E$ of a system of atoms as

$$E = K(\theta - \theta_0)^2$$

where $\theta_0$ is the equilibrium value of the angle and $K$ is a prefactor. Note that the usual 1/2 factor is included in $K$. The form of the potential is identical to that used in angle_style harmonic, but in this case, the atoms do not need to be explicitly bonded.

Only a single pair_coeff command is used with this style which specifies a potential file with parameters for specified elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of elements to atom types
See the `pair_coeff` doc page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.nb3b.harmonic has potential values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following `pair_coeff` command:

```
pair_coeff * * SiC.nb3b.harmonic Si Si Si C
```

The first 2 arguments must be `* *` so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the potential file. The final C argument maps LAMMPS atom type 4 to the C element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when the potential is used as part of the `hybrid` pair style. The NULL values are placeholders for atom types that will be used with other potentials. An example of a `pair_coeff` command for use with the `hybrid` pair style is:

```
pair_coeff * * nb3b/harmonic MgOH.nb3b.harmonic Mg O H
```

Three-body non-bonded harmonic files in the `potentials` directory of the LAMMPS distribution have a “.nb3b.harmonic” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements.

Each entry has six arguments. The first three are atom types as referenced in the LAMMPS input file. The first argument specifies the central atom. The fourth argument indicates the $K$ parameter. The fifth argument indicates $\theta_0$. The sixth argument indicates a separation cutoff in Angstroms.

For a given entry, if the second and third arguments are identical, then the entry is for a cutoff for the distance between types 1 and 2 (values for $K$ and $\theta_0$ are irrelevant in this case).

For a given entry, if the first three arguments are all different, then the entry is for the $K$ and $\theta_0$ parameters (the cutoff in this case is irrelevant).

It is required that the potential file contains entries for all permutations of the elements listed in the `pair_coeff` command. If certain combinations are not parameterized the corresponding parameters should be set to zero. The potential file can also contain entries for additional elements which are not used in a particular simulation; LAMMPS ignores those entries.

---

pair_coeff * * 0.01 5.4 8.0 7.0
pair_coeff 1 1 0.01 4.4 7.0 6.0
```
20.166.3 Description

Style *nm* computes site-site interactions based on the N-M potential by Clarke, mainly used for ionic liquids. A site can represent a single atom or a united-atom site. The energy of an interaction has the following form:

\[ E = \frac{E_0}{(n-m)} \left[ m \left( \frac{r_0}{r} \right)^n - n \left( \frac{r_0}{r} \right)^m \right] \quad r < r_c \]

where \( r_c \) is the cutoff.

Style *nm/cut/coul/cut* adds a Coulombic pairwise interaction given by

\[ E = \frac{Cq_i q_j}{\epsilon r} \quad r < r_c \]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, and \( \epsilon \) is the dielectric constant which can be set by the *dielectric* command. If one cutoff is specified in the *pair_style* command, it is used for both the N-M and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the N-M and Coulombic terms respectively.

Styles *nm/cut/coul/long* compute the same Coulombic interactions as style *nm/cut/coul/cut* except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the *kspace_style* command and its *ewald* or *pppm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

For all of the *nm* pair styles, the following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands.

- \( E_0 \) (energy units)
- \( r_0 \) (distance units)
- \( n \) (unitless)
- \( m \) (unitless)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global N-M and Coulombic cutoffs specified in the *pair_style* command are used. If only one cutoff is specified, it is used as the cutoff for both N-M and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the N-M and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style *nm*, since it has no Coulombic terms.

For *nm/cut/coul/long* only the N-M cutoff can be specified since a Coulombic cutoff cannot be specified for an individual IJ type pair. All type pairs use the same global Coulombic cutoff specified in the *pair_style* command.

20.166.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

All of the *nm* pair styles supports the *pair_modify* shift option for the energy of the pair interaction.

The *nm/cut/coul/long* pair styles support the *pair_modify* table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the *nm* pair styles support the *pair_modify* tail option for adding a long-range tail correction to the energy and pressure for the N-M portion of the pair interaction.
All of the *nm* pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

All of the *nm* pair styles can only be used via the *pair* keyword of the *run_style respa* command. They do not support the *inner, middle, outer* keywords.

Styles with a *gpu, intel, kk, omp, or opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.166.5 Restrictions

These pair styles are part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

### 20.166.6 Related commands

*pair_coeff*

### 20.166.7 Default

none

### 20.167 pair_style none command

#### 20.167.1 Syntax

```
pair_style none
```
20.167.2 Examples

```
pair_style none
```

20.167.3 Description

Using a pair style of none means pair forces and energies are not computed.

With this choice, the force cutoff is 0.0, which means that only atoms within the neighbor skin distance (see the `neighbor` command) are communicated between processors. You must insure the skin distance is large enough to acquire atoms needed for computing bonds, angles, etc.

A pair style of none will also prevent pairwise neighbor lists from being built. However if the `neighbor` style is `bin`, data structures for binning are still allocated. If the neighbor skin distance is small, then these data structures can consume a large amount of memory. So you should either set the neighbor style to `nsq` or set the skin distance to a larger value.

See the `pair_style zero` for a way to trigger the building of a neighbor lists, but compute no pairwise interactions.

20.172.3 Description

The oxdna pair styles compute the pairwise-additive parts of the oxDNA force field for coarse-grained modelling of DNA. The effective interaction between the nucleotides consists of potentials for the excluded volume interaction oxdna/excv, the stacking oxdna/stk, cross-stacking oxdna/xstk and coaxial stacking interaction oxdna/coaxstk as well as the hydrogen-bonding interaction oxdna/hbond between complementary pairs of nucleotides on opposite strands. Average sequence or sequence-dependent stacking and base-pairing strengths are supported (Sulc). Quasi-unique base-pairing between nucleotides can be achieved by using more complementary pairs of atom types like 5-8 and 6-7, 9-12 and 10-11, 13-16 and 14-15, etc. This prevents the hybridization of in principle complementary bases within Ntypes/4 bases up and down along the backbone.

The exact functional form of the pair styles is rather complex. The individual potentials consist of products of modulation factors, which themselves are constructed from a number of more basic potentials (Morse, Lennard-Jones,
harmonic angle and distance) as well as quadratic smoothing and modulation terms. We refer to *(Ouldridge-DPhil)* and *(Ouldridge)* for a detailed description of the oxDNA force field.

**Note:** These pair styles have to be used together with the related oxDNA bond style *oxdna/fene* for the connectivity of the phosphate backbone (see also documentation of *bond_style oxdna/fene*). Most of the coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model. Exceptions are the first four coefficients after *oxdna/stk* (seq=seqdep, T=0.1, xi=1.3448 and kappa=2.6568 in the above example) and the first coefficient after *oxdna/hbond* (seq=seqdep in the above example). When using a Langevin thermostat, e.g. through *fix langevin* or *fix nve/dote/langevin* the temperature coefficients have to be matched to the one used in the fix.

Example input and data files for DNA duplexes can be found in examples/USER/cgdna/examples/oxDNA/ and /oxDNA2/. A simple python setup tool which creates single straight or helical DNA strands, DNA duplexes or arrays of DNA duplexes can be found in examples/USER/cgdna/util/.

Please cite *(Henrich)* in any publication that uses this implementation. The article contains general information on the model, its implementation and performance as well as the structure of the data and input file. The preprint version of the article can be found here. Please cite also the relevant oxDNA publications *(Ouldridge)*, *(Ouldridge-DPhil)* and *(Sulc)*.

### 20.172.4 Restrictions

20.178.3 Description

The `oxdna2` pair styles compute the pairwise-additive parts of the oxDNA force field for coarse-grained modelling of DNA. The effective interaction between the nucleotides consists of potentials for the excluded volume interaction `oxdna2/excv`, the stacking `oxdna2/stk`, cross-stacking `oxdna2/xstk` and coaxial stacking interaction `oxdna2/coaxstk`, electrostatic Debye-Hueckel interaction `oxdna2/dh` as well as the hydrogen-bonding interaction `oxdna2/hbond` between complementary pairs of nucleotides on opposite strands. Average sequence or sequence-dependent stacking and base-pairing strengths are supported. Quasi-unique base-pairing between nucleotides can be achieved by using more complementary pairs of atom types like 5-8 and 6-7, 9-12 and 10-11, 13-16 and 14-15, etc. This prevents the hybridization of in principle complementary bases within Ntypes/4 bases up and down along the backbone.

The exact functional form of the pair styles is rather complex. The individual potentials consist of products of modulation factors, which themselves are constructed from a number of more basic potentials (Morse, Lennard-Jones, harmonic angle and distance) as well as quadratic smoothing and modulation terms. We refer to (Snodin) and the original oxDNA publications (Ouldridge-DPhil) and (Ouldridge) for a detailed description of the oxDNA2 force field.

Note: These pair styles have to be used together with the related oxDNA2 bond style `oxdna2/fene` for the connectivity of the phosphate backbone (see also documentation of `bond_style oxdna2/fene`). Most of the coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model. Exceptions are the first four coefficients after `oxdna2/stk` (seq=seqdep, T=0.1, xi=1.3523 and kappa=2.6717 in the above example), the first coefficient after `oxdna2/hbond` (seq=seqdep in the above example) and the three coefficients after `oxdna2/dh` (T=0.1, rhos=0.5, qeff=0.815 in the above example). When using a Langevin thermostat e.g. through `fix langevin` or `fix nve/dotc/langevin` the temperature coefficients have to be matched to the one used in the fix.

Example input and data files for DNA duplexes can be found in examples/USER/cgdna/examples/oxDNA/ and /oxDNA2/. A simple python setup tool which creates single straight or helical DNA strands, DNA duplexes or arrays of DNA duplexes can be found in examples/USER/cgdna/util/.

Please cite (Henrich) in any publication that uses this implementation. The article contains general information on the model, its implementation and performance as well as the structure of the data and input file. The preprint version of the article can be found here. Please cite also the relevant oxDNA2 publications (Snodin) and (Sulc).
20.178.4 Restrictions

These pair styles can only be used if LAMMPS was built with the USER-CGDNA package and the MOLECULE and ASPHERE package. See the Build package doc page for more info.

\]
20.188.3 Description

The peridynamic pair styles implement material models that can be used at the mesoscopic and macroscopic scales. See this document for an overview of LAMMPS commands for Peridynamics modeling.

Style peri/pmb implements the Peridynamic bond-based prototype microelastic brittle (PMB) model.

Style peri/lps implements the Peridynamic state-based linear peridynamic solid (LPS) model.

Style peri/ves implements the Peridynamic state-based linear peridynamic viscoelastic solid (VES) model.

Style peri/eps implements the Peridynamic state-based elastic-plastic solid (EPS) model.

The canonical papers on Peridynamics are (Silling 2000) and (Silling 2007). The implementation of Peridynamics in LAMMPS is described in (Parks). Also see the PDLAMMPS user guide for more details about its implementation.

The peridynamic VES and EPS models in PDLAMMPS were implemented by R. Rahman and J. T. Foster at University of Texas at San Antonio. The original VES formulation is described in “(Mitchell2011)” and the original EPS formulation is in “(Mitchell2011a)”. Additional PDF docs that describe the VES and EPS implementations are include in the LAMMPS distribution in doc/PDF/PDLammps_VES.pdf and doc/PDF/PDLammps_EPS.pdf. For questions regarding the VES and EPS models in LAMMPS you can contact R. Rahman (rezwanur.rahman at utsa.edu).

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below.

For the peri/pmb style:

- $c$ (energy/distance/volume^2 units)
- horizon (distance units)
- s00 (unitless)
- $\alpha$ (unitless)

$C$ is the effectively a spring constant for Peridynamic bonds, the horizon is a cutoff distance for truncating interactions, and s00 and $\alpha$ are used as a bond breaking criteria. The units of $c$ are such that $c$/distance = stiffness/volume^2, where stiffness is energy/distance^2 and volume is distance^3. See the users guide for more details.

For the peri/lps style:

- $K$ (force/area units)
- $G$ (force/area units)
- horizon (distance units)
- s00 (unitless)
- $\alpha$ (unitless)

$K$ is the bulk modulus and $G$ is the shear modulus. The horizon is a cutoff distance for truncating interactions, and s00 and $\alpha$ are used as a bond breaking criteria. See the users guide for more details.

For the peri/ves style:

- $K$ (force/area units)
- $G$ (force/area units)
- horizon (distance units)
- s00 (unitless)
- $\alpha$ (unitless)
**LAMMPS Documentation**

- \( m_{\text{lambdai}} \) (unitless)
- \( m_{\text{taubi}} \) (unitless)

\( K \) is the bulk modulus and \( G \) is the shear modulus. The horizon is a cutoff distance for truncating interactions, and \( s00 \) and \( \alpha \) are used as a bond breaking criteria. \( m_{\text{lambdai}} \) and \( m_{\text{taubi}} \) are the viscoelastic relaxation parameter and time constant, respectively. \( m_{\text{lambdai}} \) varies within zero to one. For very small values of \( m_{\text{lambdai}} \) the viscoelastic model responds very similar to a linear elastic model. For details please see the description in “(Mitchell2011)”.

For the \( \text{peri/eps} \) style:

- \( K \) (force/area units)
- \( G \) (force/area units)
- horizon (distance units)
- \( s00 \) (unitless)
- \( \alpha \) (unitless)
- \( m_{\text{yield\_stress}} \) (force/area units)

\( K \) is the bulk modulus and \( G \) is the shear modulus. The horizon is a cutoff distance and \( s00 \) and \( \alpha \) are used as a bond breaking criteria. \( m_{\text{yield\_stress}} \) is the yield stress of the material. For details please see the description in “(Mitchell2011a)”.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix} command-line switch when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

### 20.188.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

These pair styles do not support the \textit{pair\_modify} shift option.

The \textit{pair\_modify} table and tail options are not relevant for these pair styles.

These pair styles write their information to binary restart files, so \textit{pair\_style} and \textit{pair\_coeff} commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the \textit{pair} keyword of the \textit{run\_style respa} command. They do not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.
20.188.5 Restrictions

All of these styles are part of the PERI package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

pair_coeff * * GaN_sw.poly Ga N
```
20.189.3 Description

The *polymorphic* pair style computes a 3-body free-form potential *(Zhou)* for the energy \( E \) of a system of atoms as

\[
E = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} [(1 - \delta_{ij}) \cdot U_{ij} (r_{ij}) - (1 - \eta_{ij}) \cdot F_{ij} (X_{ij}) \cdot V_{ij} (r_{ij})]
\]

\[
X_{ij} = \sum_{k=i+1, k \neq j}^{N} W_{IK} (r_{ik}) \cdot G_{JIK} (\cos \theta_{jik}) \cdot P_{JIK} (\Delta r_{jik})
\]

where \( I, J, K \) represent species of atoms \( i, j, \) and \( k \), and \( i_1, ..., i_N \) represents a list of \( i \)’s neighbors, \( \delta_{ij} \) is a Dirac constant (i.e., \( \delta_{ij} = 1 \) when \( i = j \), and \( \delta_{ij} = 0 \) otherwise), \( \eta_{ij} \) is similar constant that can be set either to \( \eta_{ij} = \delta_{ij} \) or \( \eta_{ij} = 1 - \delta_{ij} \) depending on the potential type, \( U_{ij} (r_{ij}), V_{ij} (r_{ij}), W_{IK} (r_{ik}) \) are pair functions, \( G_{JIK} (\cos \theta_{jik}) \) is an angular function, \( P_{JIK} (\Delta r_{jik}) \) is a function of atomic spacing differential \( \Delta r_{jik} = r_{ij} - \xi_{ij} \cdot r_{ik} \) with \( \xi_{ij} \) being a pair-dependent parameter, and \( F_{ij} (X_{ij}) \) is a function of the local environment variable \( X_{ij} \). This generic potential is fully defined once the constants \( \eta_{ij} \) and \( \xi_{ij} \), and the six functions \( U_{ij} (r_{ij}), V_{ij} (r_{ij}), W_{IK} (r_{ik}), G_{JIK} (\cos \theta_{jik}), P_{JIK} (\Delta r_{jik}) \) and \( F_{ij} (X_{ij}) \) are given. Here LAMMPS uses a global parameter \( \eta \) to represent \( \eta_{ij} \). When \( \eta = 1 \), \( \eta_{ij} = 1 - \delta_{ij} \), otherwise \( \eta_{ij} = \delta_{ij} \). Additionally, \( \eta = 3 \) indicates that the function \( P_{JIK} (\Delta r) \) depends on species \( I, J \) and \( K \), otherwise \( P_{JIK} (\Delta r) = P_{IK} (\Delta r) \) only depends on species \( I \) and \( K \). Note that these six functions are all one dimensional, and hence can be provided in a tabular form. This allows users to design different potentials solely based on a manipulation of these functions. For instance, the potential reduces to a Stillinger-Weber potential *(SW)* if we set

\[
\eta_{ij} = \delta_{ij} (\eta = 2 \text{ or } \eta = 0), \xi_{ij} = 0
\]

\[
U_{ij} (r) = A_{IJ} \cdot c_{IJ} \cdot \left( \frac{\sigma_{IJ}}{r} \right)^q \cdot \left[ B_{IJ} \cdot \left( \frac{\sigma_{IJ}}{r} \right)^{p-q} - 1 \right] \cdot \exp \left( \frac{\sigma_{IJ}}{r-a_{IJ} \cdot \sigma_{IJ}} \right)
\]

\[
V_{ij} (r) = \sqrt{\lambda_{IJ} \cdot c_{IJ} \cdot \exp \left( \frac{\gamma_{IJ} \cdot \sigma_{IJ}}{r-a_{IJ} \cdot \sigma_{IJ}} \right)}
\]

\[
F_{ij} (X) = -X
\]

\[
P_{JIK} (\Delta r) = P_{IK} (\Delta r) = 1
\]

\[
W_{IJ} (r) = \sqrt{\lambda_{IJ} \cdot c_{IJ} \cdot \exp \left( \frac{\gamma_{IJ} \cdot \sigma_{IJ}}{r-a_{IJ} \cdot \sigma_{IJ}} \right)}
\]

\[
G_{JIK} (\cos \theta) = \left( \cos \theta + \frac{1}{3} \right)^2
\]

The potential reduces to a Tersoff potential *(Tersoff or Albe)* if we set

\[
\eta_{ij} = \delta_{ij} (\eta = 2 \text{ or } \eta = 0), \xi_{ij} = 1
\]

\[
U_{ij} (r) = \frac{D_{c,ij}}{S_{ij} - 1} \cdot \exp \left[ -\beta_{ij} \sqrt{2S_{ij}} (r - r_{c,ij}) \right] \cdot f_{c,ij} (r)
\]

\[
V_{ij} (r) = \frac{S_{ij} \cdot D_{c,ij}}{S_{ij} - 1} \cdot \exp \left[ -\beta_{ij} \sqrt{2} \frac{S_{ij}}{2} (r - r_{c,ij}) \right] \cdot f_{c,ij} (r)
\]

\[
F_{ij} (X) = (1 + X)^{-\frac{1}{2}}
\]

\[
P_{JIK} (\Delta r) = P_{IK} (\Delta r) = \exp (2\mu_{IK} \cdot \Delta r)
\]

\[
W_{IJ} (r) = f_{c,ij} (r)
\]

\[
G_{JIK} (\cos \theta) = \gamma_{IK} \left[ 1 + \frac{c_{IK}^2}{a_{IK}^2} - \frac{c_{IK}^2}{a_{IK}^2 + (h_{IK} + \cos \theta)^2} \right]
\]
where
\[
f_{c,IJ}(r) = \begin{cases} 
1, r \leq R_{IJ} - D_{IJ} \\
\frac{1}{2} + \frac{1}{2} \cos \left[ \frac{\pi(r + D_{IJ} - R_{IJ})}{2D_{IJ}} \right], R_{IJ} - D_{IJ} < r < R_{IJ} + D_{IJ} \\
0, r \geq R_{IJ} + D_{IJ}
\end{cases}
\]

The potential reduces to a modified Stillinger-Weber potential (Zhou3) if we set
\[
\eta_{ij} = \delta_{ij}(\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 0
\]
\[
U_{IJ}(r) = \varphi_{R,IJ}(r) - \varphi_{A,IJ}(r)
\]
\[
V_{IJ}(r) = u_{IJ}(r)
\]
\[
F_{IJ}(X) = -X
\]
\[
P_{JIK}(\Delta r) = P_{IK}(\Delta r) = 1
\]
\[
W_{IJ}(r) = u_{IJ}(r)
\]
\[
G_{JIK}(\cos \theta) = g_{JIK}(\cos \theta)
\]

The potential reduces to a Rockett-Tersoff potential (Wang3) if we set
\[
\eta_{ij} = \delta_{ij}(\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 1
\]
\[
U_{IJ}(r) = A_{IJ} \exp \left( -\lambda_{1,IJ} \cdot r \right) f_{c,IJ}(r) f_{ca,IJ}(r)
\]
\[
V_{IJ}(r) = \begin{cases} 
B_{IJ} \exp \left( -\lambda_{2,IJ} \cdot r \right) f_{c,IJ}(r) + A_{IJ} \exp \left( -\lambda_{1,IJ} \cdot r \right) f_{c,IJ}(r) \left[ 1 - f_{ca,IJ}(r) \right]
\end{cases}
\]
\[
F_{IJ}(X) = \left[ 1 + (\beta_{IJ} X)^n \right]^{-\frac{1}{n}}
\]
\[
P_{JIK}(\Delta r) = P_{IK}(\Delta r) = \exp \left( \lambda_{3,IK} \cdot \Delta r^3 \right)
\]
\[
W_{IJ}(r) = f_{c,IJ}(r)
\]
\[
G_{JIK}(\cos \theta) = 1 + \frac{c_{IK}^2}{d_{IK}^2} - \frac{c_{IK}^2}{d_{IK}^2 + (h_{IK} + \cos \theta)^2}
\]

where \(f_{ca,IJ}(r)\) is similar to the \(f_{c,IJ}(r)\) defined above:
\[
f_{ca,IJ}(r) = \begin{cases} 
1, r \leq R_{a,IJ} - D_{a,IJ} \\
\frac{1}{2} + \frac{1}{2} \cos \left[ \frac{\pi(r + D_{a,IJ} - R_{a,IJ})}{2D_{a,IJ}} \right], R_{a,IJ} - D_{a,IJ} < r < R_{a,IJ} + D_{a,IJ} \\
0, r \geq R_{a,IJ} + D_{a,IJ}
\end{cases}
\]

The potential becomes the embedded atom method (Daw) if we set
\[
\eta_{ij} = 1 - \delta_{ij}(\eta = 1), \xi_{IJ} = 0
\]
\[
U_{IJ}(r) = \phi_{IJ}(r)
\]
\[
V_{IJ}(r) = 1
\]
\[
F_{IJ}(X) = -2F_{I}(X)
\]
\[
P_{JIK}(\Delta r) = P_{IK}(\Delta r) = 1
\]
\[
W_{IJ}(r) = f_{J}(r)
\]
\[
G_{JIK}(\cos \theta) = 1
\]

In the embedded atom method case, \(\phi_{IJ}(r)\) is the pair energy, \(F_{I}(X)\) is the embedding energy, \(X\) is the local electron density, and \(f_{J}(r)\) is the atomic electron density function.
The potential reduces to another type of Tersoff potential (Zhou4) if we set

\[ \eta_{ij} = \delta_{ij} (\eta = 3), \xi_{IJ} = 1 \]

\[ U_{IJ}(r) = \frac{D_{e,IJ}}{S_{IJ} - 1} \cdot \exp \left[ -\frac{\beta_{IJ}}{2S_{IJ}} (r - r_{c,ij}) \right] \cdot f_{c,ij}(r) \cdot T_{IJ}(r) + V_{ZBL,IJ}(r) \left[ 1 - T_{IJ}(r) \right] \]

\[ V_{IJ}(r) = \frac{S_{IJ} \cdot D_{e,ij}}{S_{IJ} - 1} \cdot \exp \left[ -\frac{\beta_{IJ}}{S_{IJ}} (r - r_{c,ij}) \right] \cdot f_{c,ij}(r) \cdot T_{IJ}(r) \]

\[ F_{IJ}(X) = (1 + X)^{-1/2} \]

\[ P_{JIK}(\Delta r) = \omega_{JIK} \cdot \exp (\alpha_{JIK} \cdot \Delta r) \]

\[ W_{IJ}(r) = f_{c,ij}(r) \]

\[ G_{JIK}(\cos \theta) = \gamma_{JIK} \left[ 1 + \frac{c_{JIK}^2}{d_{JIK}^2} - \frac{c_{JIK}^2}{d_{JIK}^2} + (h_{JIK} + \cos \theta)^2 \right] \]

\[ T_{IJ}(r) = \frac{1}{1 + \exp \left[ -b_{f,ij}(r - r_{f,ij}) \right]} \]

\[ V_{ZBL,IJ}(r) = 14.4 \cdot \frac{Z_i \cdot Z_j}{r} \sum_{k=1}^{4} \mu_k \cdot \exp \left[ -\nu_k (Z_i^{0.23} + Z_j^{0.23}) r \right] \]

where \( f_{c,ij}(r) \) is the same as defined above. This Tersoff potential differs from the one above because the \( P_{JIK}(\Delta r) \) function is now dependent on all three species \( I, J, \) and \( K \).

If the tabulated functions are created using the parameters of Stillinger-Weber, Tersoff, and EAM potentials, the polymorphic pair style will produce the same global properties (energies and stresses) and the same forces as the \( sw, tersoff, \) and \( eam \) pair styles. The polymorphic pair style also produces the same per-atom properties (energies and stresses) as the corresponding \( tersoff \) and \( eam \) pair styles. However, due to a different partitioning of global properties to per-atom properties, the polymorphic pair style will produce different per-atom properties (energies and stresses) as the \( sw \) pair style. This does not mean that polymorphic pair style is different from the \( sw \) pair style. It just means that the definitions of the atom energies and atom stresses are different.

Only a single pair_coeff command is used with the polymorphic pair style which specifies a potential file for all needed elements. These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:

- filename
- \( N \) element names = mapping of polymorphic potential elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file. Several files for polymorphic potentials are included in the potentials directory of the LAMMPS distribution. They have a “poly” suffix.

As an example, imagine the GaN_tersoff.poly file has tabulated functions for Ga-N tersoff potential. If your LAMMPS simulation has 4 atom types and you want the first 3 to be Ga, and the fourth to be N, you would use the following pair_coeff command:

```
pair_coeff * * GaN_tersoff.poly Ga Ga Ga N
```

The first two arguments must be * * to span all pairs of LAMMPS atom types. The first three Ga arguments map LAMMPS atom types 1,2,3 to the Ga element in the polymorphic file. The final N argument maps LAMMPS atom type 4 to the N element in the polymorphic file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when an polymorphic potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Potential files in the potentials directory of the LAMMPS distribution have a “.poly” suffix. At the beginning of the files, an unlimited number of lines starting with ‘#’ are used to describe the potential and are ignored by LAMMPS. The next line lists two numbers:
Here `ntypes` represent total number of species defined in the potential file. $\eta = 1$ reduces to embedded atom method, $\eta = 3$ assumes a three species dependent $P_{JIK}(\Delta r)$ function, and all other values of $\eta$ assume a two species dependent $P_{JK}(\Delta r)$ function. The value of `ntypes` must equal the total number of different species defined in the `pair_coeff` command. The next `ntypes` lines each lists two numbers and a character string representing atomic number, atomic mass, and name of the species of the `ntypes` elements:

```
atomic-number atomic-mass element-name(1)
atomic-number atomic-mass element-name(2)
...
atomic-number atomic-mass element-name(ntypes)
```

The next line contains four numbers:

```
nr ntheta nx xmax
```

Here `nr` is total number of tabular points for radial functions $U$, $V$, $W$, $P$, `ntheta` is total number of tabular points for the angular function $G$, `nx` is total number of tabular points for the function $F$, `xmax` is a maximum value of the argument of function $F$. Note that the pair functions $U_{IJ}(r)$, $V_{IJ}(r)$, $W_{IJ}(r)$ are uniformly tabulated between 0 and cutoff distance of the $IJ$ pair, $G_{JIK}(\cos \theta)$ is uniformly tabulated between -1 and 1, $P_{JIK}(\Delta r)$ is uniformly tabulated between $-rcmax$ and $rcmax$ where $rcmax$ is the maximum cutoff distance of all pairs, and $F_{IJ}(X)$ is uniformly tabulated between 0 and `xmax`. Linear extrapolation is assumed if actual simulations exceed these ranges.

The next `ntypes*(ntypes+1)/2` lines contain two numbers:

```
cut xi(1)
cut xi(2)
...
cut xi(ntypes*(ntypes+1)/2)
```

Here `cut` means the cutoff distance of the pair functions, “$xi$” is $\xi$ as defined in the potential functions above. The `ntypes*(ntypes+1)/2` lines are related to the pairs according to the sequence of first `ii` (self) pairs, $i = 1, 2, \ldots, ntypes$, and then `ij` (cross) pairs, $i = 1, 2, \ldots, ntypes-1$, and $j = i+1, i+2, \ldots, ntypes$ (i.e., the sequence of the `ij` pairs follows 11, 22, \ldots, 12, 13, 14, \ldots, 23, 24, \ldots).

In the final blocks of the potential file, $U$, $V$, $W$, $P$, $G$, and $F$ functions are listed sequentially. First, $U$ functions are given for each of the `ntypes*(ntypes+1)/2` pairs according to the sequence described above. For each of the pairs, `nr` values are listed. Next, similar arrays are given for $V$ and $W$ functions. If $P$ functions depend only on pair species, i.e., $\eta \neq 3$, then $P$ functions are also listed the same way the next. If $P$ functions depend on three species, i.e., $\eta = 3$, then $P$ functions are listed for all the `ntypes*ntypes*ntypes` IJK triplets in a natural sequence $I$ from 1 to `ntypes`, $J$ from 1 to `ntypes`, and $K$ from 1 to `ntypes` (i.e., IJK = 111, 112, 113, \ldots, 121, 122, 123 \ldots, 211, 212, \ldots). Next, $G$ functions are listed for all the `ntypes*ntypes*ntypes` IJK triplets similarly. For each of the $G$ functions, `ntheta` values are listed. Finally, $F$ functions are listed for all the `ntypes*(ntypes+1)/2` pairs in the same sequence as described above. For each of the $F$ functions, `nx` values are listed.
20.189.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair styles does not support the `pair_modify` shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

20.189.5 Restrictions

If using create_atoms command, atomic masses must be defined in the input script. If using read_data, atomic masses must be defined in the atomic structure data file.

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair potential requires the `newton` setting to be “on” for pair interactions.

The potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use any LAMMPS units, but you would need to create your own potential files.

pair_coeff  *  *  python  py_pot.LJCutSPCE  OW  NULL
```

20.190.3 Description

The `python` pair style provides a way to define pairwise additive potential functions as python script code that is loaded into LAMMPS from a python file which must contain specific python class definitions. This allows to rapidly evaluate different potential functions without having to modify and re-compile LAMMPS. Due to python being an interpreted language, however, the performance of this pair style is going to be significantly slower (often between 20x and 100x) than corresponding compiled code. This penalty can be significantly reduced through generating tabulations from the python code through the `pair_write` command, which is supported by this style.

Only a single `pair_coeff` command is used with the `python` pair style which specifies a python class inside a python module or a file that LAMMPS will look up in the current directory, a folder pointed to by the `LAMMPS_POTENTIALS` environment variable or somewhere in your python path. A single python module can hold multiple python pair class definitions. The class definitions itself have to follow specific rules that are explained below.

Atom types in the python class are specified through symbolic constants, typically strings. These are mapped to LAMMPS atom types by specifying N additional arguments after the class name in the `pair_coeff` command, where N must be the number of currently defined atom types:

As an example, imagine a file `py_pot.py` has a python potential class names `LJCutMelt` with parameters and potential functions for a two Lennard-Jones atom types labeled as ‘LJ1’ and ‘LJ2’. In your LAMMPS input and you would have defined 3 atom types, out of which the first two are supposed to be using the ‘LJ1’ parameters and the third the ‘LJ2’ parameters, then you would use the following `pair_coeff` command:

```
pair_coeff  *  *  py_pot.LJCutMelt  LJ1  LJ1  LJ2
```

The first two arguments `must` be `* *` so as to span all LAMMPS atom types. The first two LJ1 arguments map LAMMPS atom types 1 and 2 to the LJ1 atom type in the LJCutMelt class of the `py_pot.py` file. The final LJ2 argument maps LAMMPS atom type 3 to the LJ2 atom type the python file. If a mapping value is specified as NULL, the mapping is not performed, any pair interaction with this atom type will be skipped. This can be used when a `python` potential is used as part of the `hybrid` or `hybrid/overlay` pair style. The NULL values are then placeholders for atom types that will be used with other potentials.

The python potential file has to start with the following code:

```
from __future__ import print_function

class LAMMPSPairPotential(object):
    def __init__(self):
        self.pmap=dict()
        self.units='lj'
    def map_coeff(self,name,ltype):
        self.pmap[ltype]=name
    def check_units(self,units):
        if (units != self.units):
            raise Exception("Conflicting units: %s vs. %s" % (self.units,units))
```

20.190. pair_style python command
Any classes with definitions of specific potentials have to be derived from this class and should be initialize in a similar fashion to the example given below.

**Note:** The class constructor has to set up a data structure containing the potential parameters supported by this class. It should also define a variable `self.units` containing a string matching one of the options of LAMMPS’ `units` command, which is used to verify, that the potential definition in the python class and in the LAMMPS input match.

Here is an example for a single type Lennard-Jones potential class `LJCutMelt` in reduced units, which defines an atom type `lj` for which the parameters epsilon and sigma are both 1.0:

```python
class LJCutMelt(LAMMPSPairPotential):
    def __init__(self):
        super(LJCutMelt, self).__init__()
        # set coeffs: 48*eps*sig**12, 24*eps*sig**6,
        # 4*eps*sig**12, 4*eps*sig**6
        self.units = 'lj'
        self.coeff = {'lj' : {'lj' : (48.0,24.0,4.0,4.0)}}
```

The class also has to provide two methods for the computation of the potential energy and forces, which have be named `compute_force`, and `compute_energy`, which both take 3 numerical arguments:

- `rsq` = the square of the distance between a pair of atoms (float)
- `itype` = the (numerical) type of the first atom
- `jtype` = the (numerical) type of the second atom

This functions need to compute the force and the energy, respectively, and use the result as return value. The functions need to use the `pmap` dictionary to convert the LAMMPS atom type number to the symbolic value of the internal potential parameter data structure. Following the `LJCutMelt` example, here are the two functions:

```python
def compute_force(self, rsq, itype, jtype):
    coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
    r2inv = 1.0/rsq
    r6inv = r2inv*r2inv*r2inv
    lj1 = coeff[0]
    lj2 = coeff[1]
    return (r6inv * (lj1*r6inv - lj2))*r2inv

def compute_energy(self, rsq, itype, jtype):
    coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
    r2inv = 1.0/rsq
    r6inv = r2inv*r2inv*r2inv
    lj3 = coeff[2]
    lj4 = coeff[3]
    return (r6inv * (lj3*r6inv - lj4))
```

**Note:** for consistency with the C++ pair styles in LAMMPS, the `compute_force` function follows the conventions of the Pair::single() methods and does not return the full force, but the force scaled by the distance between the two atoms, so this value only needs to be multiplied by delta x, delta y, and delta z to conveniently obtain the three components of the force vector between these two atoms.

**Note:** The evaluation of scripted python code will slow down the computation pair-wise interactions quite significantly. However, this can be largely worked around through using the python pair style not for the actual simulation, but
to generate tabulated potentials on the fly using the \textit{pair\_write} command. Please see below for an example LAMMPS input of how to build a table file:

\begin{verbatim}
pair_style python 2.5
pair_coeff * * py\_pot.LJCutMelt lj
shell rm -f melt.table
pair_write 1 1 2000 rsq 0.01 2.5 lj1\_lj2.table lj
\end{verbatim}

Note that it is strongly recommended to try to \textbf{delete} the potential table file before generating it. Since the \textit{pair\_write} command will always \textbf{append} to a table file, while pair style table will use the \textbf{first match}. Thus when changing the potential function in the python class, the table pair style will still read the old variant unless the table file is first deleted.

After switching the pair style to \textit{table}, the potential tables need to be assigned to the LAMMPS atom types like this:

\begin{verbatim}
pair_style table linear 2000
pair_coeff 1 1 melt.table lj
\end{verbatim}

This can also be done for more complex systems. Please see the \texttt{examples/python} folders for a few more examples.

---

\section*{20.190.4 Mixing, shift, table, tail correction, restart, rRESPA info}

Mixing of potential parameters has to be handled inside the provided python module. The python pair style simply assumes that force and energy computation can be correctly performed for all pairs of atom types as they are mapped to the atom type labels inside the python potential class.

This pair style does not support the \textit{pair\_modify} shift, table, and tail options.

This pair style does not write its information to \texttt{binary restart files}, since it is stored in potential files. Thus, you need to re-specify the \texttt{pair\_style} and \texttt{pair\_coeff} commands in an input script that reads a restart file.

This pair style can only be used via the \texttt{pair} keyword of the \texttt{run\_style respa} command. It does not support the \texttt{inner}, \texttt{middle}, \texttt{outer} keywords.

---

\section*{20.190.5 Restrictions}

This pair style is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the \texttt{Build package} doc page for more info.

---

\section*{20.190.6 Related commands}

\texttt{pair\_coeff}, \texttt{pair\_write}, \texttt{pair\_style table}
20.190.7 Default

none

20.191 pair_style quip command

20.191.1 Syntax

```
pair_style quip
```

20.191.2 Examples

```
pair_style quip
pair_coeff * * gap_example.xml "Potential xml_label=GAP_2014_5_8_60_17_10_38_466"
   14
pair_coeff * * sw_example.xml "IP SW" 14
```

20.191.3 Description

Style *quip* provides an interface for calling potential routines from the QUIP package. QUIP is built separately, and then linked to LAMMPS. The most recent version of the QUIP package can be downloaded from GitHub: [https://github.com/libAtoms/QUIP](https://github.com/libAtoms/QUIP). The interface is chiefly intended to be used to run Gaussian Approximation Potentials (GAP), which are described in the following publications: (Bartok et al) and (PhD thesis of Bartok).

Only a single pair_coeff command is used with the *quip* style that specifies a QUIP potential file containing the parameters of the potential for all needed elements in XML format. This is followed by a QUIP initialization string. Finally, the QUIP elements are mapped to LAMMPS atom types by specifying N atomic numbers, where N is the number of LAMMPS atom types:

- QUIP filename
- QUIP initialization string
- N atomic numbers = mapping of QUIP elements to atom types

See the *pair_coeff* doc page for alternate ways to specify the path for the potential file.

A QUIP potential is fully specified by the filename which contains the parameters of the potential in XML format, the initialization string, and the map of atomic numbers.

GAP potentials can be obtained from the Data repository section of [http://www.libatoms.org](http://www.libatoms.org), where the appropriate initialization strings are also advised. The list of atomic numbers must be matched to the LAMMPS atom types specified in the LAMMPS data file or elsewhere.

Two examples input scripts are provided in the examples/USER/quip directory.
20.191.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.191.5 Restrictions

This pair style is part of the USER-QUIP package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

QUIP potentials are parameterized in electron-volts and Angstroms and therefore should be used with LAMMPS metal units.

QUIP potentials are generally not designed to work with the scaling factors set by the special_bonds command. The recommended setting in molecular systems is to include all interactions, i.e. to use special_bonds lj/coul 1.0 1.0 1.0. Scaling factors > 0.0 will be ignored and treated as 1.0. The only exception to this rule is if you know that your QUIP potential needs to exclude bonded, 1-3, or 1-4 interactions and does not already do this exclusion within QUIP. Then a factor 0.0 needs to be used which will remove such pairs from the neighbor list. This needs to be very carefully tested, because it may remove pairs from the neighbor list that are still required.

pair_coeff * * ffield.reax C H O N
```

20.192.3 Description

Style reax/c computes the ReaxFF potential of van Duin, Goddard and co-workers. ReaxFF uses distance-dependent bond-order functions to represent the contributions of chemical bonding to the potential energy. There is more than one version of ReaxFF. The version implemented in LAMMPS uses the functional forms documented in the supplemental information of the following paper: (Chenoweth et al., 2008). The version integrated into LAMMPS matches the most up-to-date version of ReaxFF as of summer 2010. For more technical details about the pair reax/c implementation of ReaxFF, see the (Aktulga) paper. The reax/c style was initially implemented as a stand-alone C code and is now integrated into LAMMPS as a package.

The reax/c/kk style is a Kokkos version of the ReaxFF potential that is derived from the reax/c style. The Kokkos version can run on GPUs and can also use OpenMP multithreading. For more information about the Kokkos package, see Packages details and Speed kokkos doc pages. One important consideration when using the reax/c/kk style is the choice of either half or full neighbor lists. This setting can be changed using the Kokkos package command.

The reax/c style differs from the (obsolete) “pair_style reax” command in the implementation details. The reax style was a Fortran library, linked to LAMMPS. The reax style has been removed from LAMMPS after the 12 December 2018 version.

LAMMPS provides several different versions of ffield.reax in its potentials dir, each called potentials/ffield.reax.label. These are documented in potentials/README.reax. The default ffield.reax contains parameterizations for the following elements: C, H, O, N.

The format of these files is identical to that used originally by van Duin. We have tested the accuracy of pair_style reax/c potential against the original ReaxFF code for the systems mentioned above. You can use other ffield files for specific chemical systems that may be available elsewhere (but note that their accuracy may not have been tested).

**Note:** We do not distribute a wide variety of ReaxFF force field files with LAMMPS. Adri van Duin’s group at PSU is the central repository for this kind of data as they are continuously deriving and updating parameterizations for different classes of materials. You can submit a contact request at the Materials Computation Center (MCC) website https://www.mri.psu.edu/materials-computation-center/connect-mcc, describing the material(s) you are interested in modeling with ReaxFF. They can tell you what is currently available or what it would take to create a suitable ReaxFF parameterization.

The cfile setting can be specified as NULL, in which case default settings are used. A control file can be specified which defines values of control variables. Some control variables are global parameters for the ReaxFF potential. Others define certain performance and output settings. Each line in the control file specifies the value for a control variable. The format of the control file is described below.

**Note:** The LAMMPS default values for the ReaxFF global parameters correspond to those used by Adri van Duin’s stand-alone serial code. If these are changed by setting control variables in the control file, the results from LAMMPS
Examples using *pair_style reax/c* are provided in the examples/reax sub-directory.

Use of this pair style requires that a charge be defined for every atom. See the *atom_style* and *read_data* commands for details on how to specify charges.

The ReaxFF parameter files provided were created using a charge equilibration (QEeq) model for handling the electrostatic interactions. Therefore, by default, LAMMPS requires that the *fix qeq/reax* command be used with *pair_style reax/c* when simulating a ReaxFF model, to equilibrate charge each timestep. Using the keyword *checkqeq* with the value *no* turns off the check for *fix qeq/reax*, allowing a simulation to be run without charge equilibration. In this case, the static charges you assign to each atom will be used for computing the electrostatic interactions in the system. See the *fix qeq/reax* command for details.

Using the optional keyword *lgvdw* with the value *yes* turns on the low-gradient correction of the ReaxFF/C for long-range London Dispersion, as described in the *(Liu)* paper. Force field file *ffield.reax.lg* is designed for this correction, and is trained for several energetic materials (see “Liu”). When using lg-correction, recommended value for parameter *thb* is 0.01, which can be set in the control file. Note: Force field files are different for the original or lg corrected pair styles, using wrong ffield file generates an error message.

Using the optional keyword *enobonds* with the value *yes*, the energy of atoms with no bonds (i.e. isolated atoms) is included in the total potential energy and the per-atom energy of that atom. If the value *no* is specified then the energy of atoms with no bonds is set to zero. The latter behavior is usual not desired, as it causes discontinuities in the potential energy when the bonding of an atom drops to zero.

Optional keywords *safezone*, *mincap*, and *minhbonds* are used for allocating reax/c arrays. Increasing these values can avoid memory problems, such as segmentation faults and bondchk failed errors, that could occur under certain conditions. These keywords are not used by the Kokkos version, which instead uses a more robust memory allocation scheme that checks if the sizes of the arrays have been exceeded and automatically allocates more memory.

The thermo variable *evdwl* stores the sum of all the ReaxFF potential energy contributions, with the exception of the Coulombic and charge equilibration contributions which are stored in the thermo variable *ecoul*. The output of these quantities is controlled by the *thermo* command.

This pair style tallies a breakdown of the total ReaxFF potential energy into sub-categories, which can be accessed via the *compute pair* command as a vector of values of length 14. The 14 values correspond to the following sub-categories (the variable names in italics match those used in the original FORTRAN ReaxFF code):

1. \( eb \) = bond energy
2. \( ea \) = atom energy
3. \( elp \) = lone-pair energy
4. \( emol \) = molecule energy (always 0.0)
5. \( ev \) = valence angle energy
6. \( epen \) = double-bond valence angle penalty
7. \( ecoa \) = valence angle conjugation energy
8. \( ehb \) = hydrogen bond energy
9. \( et \) = torsion energy
10. \( eco \) = conjugation energy
11. \( ew \) = van der Waals energy
12. \( ep \) = Coulomb energy
13. \( efi \) = electric field energy (always 0.0)
14. $eqeq = \text{charge equilibration energy}$

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```plaintext
compute reax all pair reax/c
variable eb equal c_reax[1]
variable ea equal c_reax[2]
[...]
variable eqeq equal c_reax[14]
thermo_style custom step temp epair v_eb v_ea [...] v_eqeq
```

Only a single pair_coeff command is used with the `reax/c` style which specifies a ReaxFF potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N indices = ReaxFF elements

The filename is the ReaxFF potential file.

In the ReaxFF potential file, near the top, after the general parameters, is the atomic parameters section that contains element names, each with a couple dozen numeric parameters. If there are M elements specified in the `ffield` file, think of these as numbered 1 to M. Each of the N indices you specify for the N atom types of LAMMPS atoms must be an integer from 1 to M. Atoms with LAMMPS type 1 will be mapped to whatever element you specify as the first index value, etc. If a mapping value is specified as NULL, the mapping is not performed. This can be used when the `reax/c` style is used as part of the `hybrid` pair style. The NULL values are placeholders for atom types that will be used with other potentials.

As an example, say your LAMMPS simulation has 4 atom types and the elements are ordered as C, H, O, N in the `ffield` file. If you want the LAMMPS atom type 1 and 2 to be C, type 3 to be N, and type 4 to be H, you would use the following pair_coeff command:

```plaintext
pair_coeff * * ffield.reax C C N H
```

The format of a line in the control file is as follows:

```plaintext
variable_name value
```

and it may be followed by an “!” character and a trailing comment.

If the value of a control variable is not specified, then default values are used. What follows is the list of variables along with a brief description of their use and default values.

- simulation_name: Output files produced by `pair_style reax/c` carry this name + extensions specific to their contents. Partial energies are reported with a “.pot” extension, while the trajectory file has “.trj” extension.

- tabulate_long_range: To improve performance, long range interactions can optionally be tabulated (0 means no tabulation). Value of this variable denotes the size of the long range interaction table. The range from 0 to long range cutoff (defined in the `ffield` file) is divided into `tabulate_long_range` points. Then at the start of simulation, we fill in the entries of the long range interaction table by computing the energies and forces resulting from van der Waals and Coulomb interactions between every possible atom type pairs present in the input system. During the simulation we consult to the long range interaction table to estimate the energy and forces between a pair of atoms. Linear interpolation is used for estimation. (default value = 0)

- energy_update_freq: Denotes the frequency (in number of steps) of writes into the partial energies file. (default value = 0)
nbrhood_cutoff: Denotes the near neighbors cutoff (in Angstroms) regarding the bonded interactions. (default value = 5.0)

hbond_cutoff: Denotes the cutoff distance (in Angstroms) for hydrogen bond interactions. (default value = 7.5. A value of 0.0 turns off hydrogen bonds)

bond_graph_cutoff: is the threshold used in determining what is a physical bond, what is not. Bonds and angles reported in the trajectory file rely on this cutoff. (default value = 0.3)

thb_cutoff: cutoff value for the strength of bonds to be considered in three body interactions. (default value = 0.001)

thb_cutoff_sq: cutoff value for the strength of bond order products to be considered in three body interactions. (default value = 0.00001)

write_freq: Frequency of writes into the trajectory file. (default value = 0)

traj_title: Title of the trajectory - not the name of the trajectory file.

atom_info: 1 means print only atomic positions + charge (default = 0)

atom_forces: 1 adds net forces to atom lines in the trajectory file (default = 0)

atom_velocities: 1 adds atomic velocities to atoms line (default = 0)

bond_info: 1 prints bonds in the trajectory file (default = 0)

angle_info: 1 prints angles in the trajectory file (default = 0)

---

20.192.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

---

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
20.192.5 Restrictions

This pair style is part of the USER-REAXC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The ReaxFF potential files provided with LAMMPS in the potentials directory are parameterized for real units. You can use the ReaxFF potential with any LAMMPS units, but you would need to create your own potential file with coefficients listed in the appropriate units if your simulation does not use “real” units.

The keyword defaults are checkqe = yes, enobonds = yes, lgvdw = no, safezone = 1.2, mincap = 50, minhbonds = 25.

20.193 pair_style resquared command

Accelerator Variants: resquared/gpu, resquared/omp

20.193.1 Syntax

```
pair_style resquared cutoff
```

- cutoff = global cutoff for interactions (distance units)

20.193.2 Examples

```
pair_style resquared 10.0
pair_coeff * * 1.0 1.0 1.7 3.4 3.4 1.0 1.0 1.0
```
20.193.3 Description

Style resquared computes the RE-squared anisotropic interaction (Everaers), (Babadi) between pairs of ellipsoidal and/or spherical Lennard-Jones particles. For ellipsoidal interactions, the potential considers the ellipsoid as being comprised of small spheres of size $\sigma$. LJ particles are a single sphere of size $\sigma$. The distinction is made to allow the pair style to make efficient calculations of ellipsoid/solvent interactions.

Details for the equations used are given in the references below and in this supplementary document.

Use of this pair style requires the NVE, NVT, or NPT fixes with the asphere extension (e.g. fix nve/asphere) in order to integrate particle rotation. Additionally, atom_style ellipsoid should be used since it defines the rotational state and the size and shape of each ellipsoidal particle.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- $A_{12}$ = Energy Prefactor/Hamaker constant (energy units)
- $\sigma$ = atomic interaction diameter (distance units)
- $\epsilon_{i,a}$ = relative well depth of type I for side-to-side interactions
- $\epsilon_{i,b}$ = relative well depth of type I for face-to-face interactions
- $\epsilon_{i,c}$ = relative well depth of type I for end-to-end interactions
- $\epsilon_{j,a}$ = relative well depth of type J for side-to-side interactions
- $\epsilon_{j,b}$ = relative well depth of type J for face-to-face interactions
- $\epsilon_{j,c}$ = relative well depth of type J for end-to-end interactions
- cutoff (distance units)

The parameters used depend on the type of the interacting particles, i.e. ellipsoids or LJ spheres. The type of a particle is determined by the diameters specified for its 3 shape parameters. If all 3 shape parameters = 0.0, then the particle is treated as an LJ sphere. The $\epsilon_{i,*}$ or $\epsilon_{j,*}$ parameters are ignored for LJ spheres. If the 3 shape parameters are $> 0.0$, then the particle is treated as an ellipsoid (even if the 3 parameters are equal to each other).

$A_{12}$ specifies the energy prefactor which depends on the types of the two interacting particles.

For ellipsoid/ellipsoid interactions, the interaction is computed by the formulas in the supplementary document referenced above. $A_{12}$ is the Hamaker constant as described in (Everaers). In LJ units:

$$A_{12} = 4\pi^2 \epsilon_{1,1}(\rho \sigma^3)^2$$

where $\rho$ gives the number density of the spherical particles composing the ellipsoids and $\epsilon_{1,1}$ determines the interaction strength of the spherical particles.

For ellipsoid/LJ sphere interactions, the interaction is also computed by the formulas in the supplementary document referenced above. $A_{12}$ has a modified form (see here for details):

$$A_{12} = 4\pi^2 \epsilon_{1,1}(\rho \sigma^3)$$

For ellipsoid/LJ sphere interactions, a correction to the distance-of-closest approach equation has been implemented to reduce the error from two particles of disparate sizes; see this supplementary document.

For LJ sphere/LJ sphere interactions, the interaction is computed using the standard Lennard-Jones formula, which is much cheaper to compute than the ellipsoidal formulas. $A_{12}$ is used as epsilon in the standard LJ formula:

$$A_{12} = \epsilon_{1,1}$$

and the specified $\sigma$ is used as the $\sigma$ in the standard LJ formula.
When one of both of the interacting particles are ellipsoids, then $\sigma$ specifies the diameter of the continuous distribution of constituent particles within each ellipsoid used to model the RE-squared potential. Note that this is a different meaning for $\sigma$ than the pair_style gayberne potential uses.

The $\epsilon_i$ and $\epsilon_j$ coefficients are defined for atom types, not for pairs of atom types. Thus, in a series of pair_coeff commands, they only need to be specified once for each atom type.

Specifically, if any of $\epsilon_{i,a}$, $\epsilon_{i,b}$, $\epsilon_{i,c}$ are non-zero, the three values are assigned to atom type I. If all the $\epsilon_i$ values are zero, they are ignored. If any of $\epsilon_{j,a}$, $\epsilon_{j,b}$, $\epsilon_{j,c}$ are non-zero, the three values are assigned to atom type J. If all three $\epsilon_i$ values are zero, they are ignored. Thus the typical way to define the $\epsilon_i$ and $\epsilon_j$ coefficients is to list their values in “pair_coeff I J” commands when I = J, but set them to 0.0 when I != J. If you do list them when I != J, you should insure they are consistent with their values in other pair_coeff commands.

Note that if this potential is being used as a sub-style of pair_style hybrid, and there is no “pair_coeff I I” setting made for RE-squared for a particular type I (because I-I interactions are computed by another hybrid pair potential), then you still need to insure the epsilon a,b,c coefficients are assigned to that type in a “pair_coeff I J” command.

For large uniform molecules it has been shown that the $\epsilon_{*,*}$ energy parameters are approximately representable in terms of local contact curvatures (Everaers):

$$\epsilon_a = \sigma \cdot \frac{a}{b \cdot c}; \epsilon_b = \sigma \cdot \frac{b}{a \cdot c}; \epsilon_c = \sigma \cdot \frac{c}{a \cdot b}$$

where a, b, and c give the particle diameters.

The last coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

**20.193.4 Mixing, shift, table, tail correction, restart, rRESPA info**

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance can be mixed, but only for sphere pairs. The default mix value is geometric. See the “pair_modify” command for details. Other type pairs cannot be mixed, due to the different meanings of the energy prefactors used to calculate the interactions and the implicit dependence of the ellipsoid-sphere interaction on the equation for the Hamaker constant presented here. Mixing of sigma and epsilon followed by calculation of the energy prefactors using the equations above is recommended.

This pair styles supports the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction, but only for sphere-sphere interactions. There is no shifting performed for ellipsoidal interactions due to the anisotropic dependence of the interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.
This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords of the run_style command.

### 20.193.5 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires that atoms be ellipsoids as defined by the atom_style ellipsoid command.

Particles acted on by the potential can be finite-size aspherical or spherical particles, or point particles. Spherical particles have all 3 of their shape parameters equal to each other. Point particles have all 3 of their shape parameters equal to 0.0.

The distance-of-closest-approach approximation used by LAMMPS becomes less accurate when high-aspect ratio ellipsoids are used.

20.196  pair_style lj/sdk/coul/msm command

Accelerator Variants: lj/sdk/coul/msm/omp

20.196.1  Syntax

```
pair_style style args
```

- style = lj/sdk or lj/sdk/coul/long
- args = list of arguments for a particular style

\textit{lj/sdk} args = cutoff
- cutoff = global cutoff for Lennard Jones interactions (distance units)

\textit{lj/sdk/coul/long} args = cutoff (cutoff2)
- cutoff = global cutoff for LJ (and Coulombic if only 1 arg) (distance units)
- cutoff2 = global cutoff for Coulombic (optional) (distance units)

20.196.2  Examples

```
pair_style lj/sdk 2.5
pair_coeff 1 1 lj12_6 1 1.1 2.8

pair_style lj/sdk/coul/long 10.0
pair_coeff 1 1 lj12_6 100.0 3.5 12.0

pair_style lj/sdk/coul/msm 10.0
pair_coeff 1 1 lj9_6 100.0 3.5 12.0
```

20.196.3  Description

The \textit{lj/sdk} styles compute a 9/6, 12/4, or 12/6 Lennard-Jones potential, given by

\[
E = \begin{cases} 
\frac{27}{4} \epsilon \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^6 & r < r_c \\
\frac{3\sqrt{3}}{2} \epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^4 & r < r_c \\
4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 & r < r_c 
\end{cases}
\]

as required for the SDK Coarse-grained MD parameterization discussed in \textit{(Shinoda)} and \textit{(DeVane)}. \( r_c \) is the cutoff.

Style \textit{lj/sdk/coul/long} computes the adds Coulombic interactions with an additional damping factor applied so it can be used in conjunction with the \textit{kspace_style} command and its \textit{ewald} or \textit{pppm} or \textit{pppm/cg} option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands, or by mixing as described below:
• cg_type (lj9_6, lj12_4, or lj12_6)
• epsilon (energy units)
• sigma (distance units)
• cutoff1 (distance units)

Note that sigma is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum. The prefactors are chosen so that the potential minimum is at -epsilon.

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

For lj/sdk/coul/long and lj/sdk/coul/msm only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.196.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/sdk pair styles cannot be mixed, since different pairs may have different exponents. So all parameters for all pairs have to be specified explicitly through the “pair_coeff” command. Defining them in a data file is also not supported, due to limitations of that file format.

All of the lj/sdk pair styles support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction.

The lj/sdk/coul/long pair styles support the pair_modify table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the lj/sdk pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/sdk and lj/cut/coul/long pair styles do not support the use of the inner, middle, and outer keywords of the run_style respa command.
20.196.5 Restrictions

All of the lj/sdk pair styles are part of the USER-CGSDK package. The lj/sdk/coul/long style also requires the KSPACE package to be built (which is enabled by default). They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

pair_style sdpd/taitwater/isothermal 300. 1. 28681
pair_coeff * * 1000.0 1430.0 2.4

20.197.3 Description

The sdpd/taitwater/isothermal style computes forces between mesoscopic particles according to the Smoothed Dissipative Particle Dynamics model described in this paper by (Espanol and Revenga) under the following assumptions:

1. The temperature is constant and uniform.
2. The shear viscosity is constant and uniform.
3. The volume viscosity is negligible before the shear viscosity.
4. The Boltzmann constant is negligible before the heat capacity of a single mesoscopic particle of fluid.
The third assumption is true for water in nearly incompressible flows. The fourth holds true for water for any reasonable size one can imagine for a mesoscopic particle.

The pressure forces between particles will be computed according to Tait’s equation of state:

$$p = B \left[ \left( \frac{\rho}{\rho_0} \right)^\gamma - 1 \right]$$

where $\gamma = 7$ and $B = c_0^2 \rho_0 / \gamma$, with $\rho_0$ being the reference density and $c_0$ the reference speed of sound.

The laminar viscosity and the random forces will be computed according to formulas described in (Espanol and Revenga).

**Warning:** Similar to brownian and dpd styles, the newton setting for pairwise interactions needs to be on when running LAMMPS in parallel if you want to ensure linear momentum conservation. Otherwise random forces generated for pairs straddling processor boundary will not be equal and opposite.

**Note:** The actual random seed used will be a mix of what you specify and other parameters like the MPI ranks. This is to ensure that different MPI tasks have distinct seeds.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above.

- $\rho_0$ reference density (mass/volume units)
- $c_0$ reference soundspeed (distance/time units)
- $h$ kernel function cutoff (distance units)

### 20.197.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the pair_modify shift, table, and tail options.

This style does not write information to binary restart files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

### 20.197.5 Restrictions

This pair style is part of the USER-SDPD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The default seed is 0 (before mixing).

20.198 pair_style smd/hertz command

20.198.1 Syntax

```
pair_style smd/hertz scale_factor
```

20.198.2 Examples

```
pair_style smd/hertz 1.0
pair_coeff 1 1 <contact_stiffness>
```

20.198.3 Description

The **smd/hertz** style calculates contact forces between SPH particles belonging to different physical bodies.

The contact forces are calculated using a Hertz potential, which evaluates the overlap between two particles (whose spatial extents are defined via its contact radius). The effect is that a particles cannot penetrate into each other. The parameter `<contact_stiffness>` has units of pressure and should equal roughly one half of the Young’s modulus (or bulk modulus in the case of fluids) of the material model associated with the SPH particles.

The parameter `scale_factor` can be used to scale the particles’ contact radii. This can be useful to control how close particles can approach each other. Usually, `scale_factor` = 1.0.

20.198.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of USER-SMD supports restarting nor minimization. rRESPA does not apply to this pair style.

20.198.5 Restrictions

This fix is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.199 pair_style smd/tlsph command

20.199.1 Syntax

```
pair_style smd/tlsph args
```

20.199.2 Examples

```
pair_style smd/tlsph
```

20.199.3 Description

The smd/tlsph style computes particle interactions according to continuum mechanics constitutive laws and a Total-Lagrangian Smooth-Particle Hydrodynamics algorithm.

This pair style is invoked with the following command:

```
pair_style smd/tlsph
pair_coeff i j *COMMON rho0 E nu Q1 Q2 hg Cp & +END
```

Here, \(i\) and \(j\) denote the LAMMPS particle types for which this pair style is defined. Note that \(i\) and \(j\) must be equal, i.e., no tlsph cross interactions between different particle types are allowed. In contrast to the usual LAMMPS pair coeff definitions, which are given solely a number of floats and integers, the tlsph pair coeff definition is organized using keywords. These keywords mark the beginning of different sets of parameters for particle properties, material constitutive models, and damage models. The pair coeff line must be terminated with the *END keyword. The use the line continuation operator & is recommended. A typical invocation of the tlsph for a solid body would consist of an equation of state for computing the pressure (the diagonal components of the stress tensor), and a material model to compute shear stresses (the off-diagonal components of the stress tensor). Damage and failure models can also be added.

Please see the SMD user guide for a complete listing of the possible keywords and material models.
20.199.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of USER-SMD supports restarting nor minimization. rRESPA does not apply to this pair style.

pair_style smd/tri_surface scale_factor
```

20.200.2 Examples

```
pair_style smd/tri_surface 1.0
pair_coeff 1 1 <contact_stiffness>
```

20.200.3 Description

The smd/tri_surface style calculates contact forces between SPH particles and a rigid wall boundary defined via the smd/wall_surface fix.

The contact forces are calculated using a Hertz potential, which evaluates the overlap between a particle (whose spatial extents are defined via its contact radius) and the triangle. The effect is that a particle cannot penetrate into the triangular surface. The parameter <contact_stiffness> has units of pressure and should equal roughly one half of the Young’s modulus (or bulk modulus in the case of fluids) of the material model associated with the SPH particle.

The parameter scale_factor can be used to scale the particles’ contact radii. This can be useful to control how close particles can approach the triangulated surface. Usually, scale_factor =1.0.
20.200.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of USER-SMD supports restarting nor minimization. rRESPA does not apply to this pair style.

20.200.5 Restrictions

This fix is part of the USER-SMD package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.200.6 Related commands

20.201 pair_style smd/ulsph command

20.201.1 Syntax

```
pair_style smd/ulsph args
```

• these keywords must be given

```
keyword = *DENSITY_SUMMATION or *DENSITY_CONTINUITY and *VELOCITY_GRADIENT, or *NO_VELOCITY_GRADIENT and *GRADIENT_CORRECTION or *NO_GRADIENT_CORRECTION
```

20.201.2 Examples

```
pair_style smd/ulsph *DENSITY_CONTINUITY *VELOCITY_GRADIENT *NO_GRADIENT_CORRECTION
```

20.201.3 Description

The smd/ulsph style computes particle interactions according to continuum mechanics constitutive laws and an updated Lagrangian Smooth-Particle Hydrodynamics algorithm.

This pair style is invoked similar to the following command:

```
pair_style smd/ulsph *DENSITY_CONTINUITY *VELOCITY_GRADIENT *NO_GRADIENT_CORRECTION
pair_coeff i j *COMMON rho0 c0 Q1 Cp hg &
  *END
```

20.201. pair_style smd/ulsph command 1975
Here, \( i \) and \( j \) denote the LAMMPS particle types for which this pair style is defined. Note that \( i \) and \( j \) can be different, i.e., ulsp h cross interactions between different particle types are allowed. However, \( i-i \) respectively \( j-j \) pair_coeff lines have to precede a cross interaction. In contrast to the usual LAMMPS pair coeff definitions, which are given solely a number of floats and integers, the ulsp h pair coeff definition is organized using keywords. These keywords mark the beginning of different sets of parameters for particle properties, material constitutive models, and damage models. The pair coeff line must be terminated with the *END keyword. The use the line continuation operator & is recommended. A typical invocation of the ulsp h for a solid body would consist of an equation of state for computing the pressure (the diagonal components of the stress tensor), and a material model to compute shear stresses (the off-diagonal components of the stress tensor).

Note that the use of *GRADIENT_CORRECTION can lead to severe numerical instabilities. For a general fluid simulation, *NO_GRADIENT_CORRECTION is recommended.

Please see the SMD user guide for a complete listing of the possible keywords and material models.

```
pair_style smtbq
pair_coeff * * ffield.smtbq.Al2O3 O Al
```

20.202.3 Description

This pair style computes a variable charge SMTB-Q (Second-Moment tight-Binding QEq) potential as described in SMTB-Q_1 and SMTB-Q_2. Briefly, the energy of metallic-oxygen systems is given by three contributions:

\[
E_{tot} = E_{ES} + E_{OO} + E_{MO}
\]

\[
E_{ES} = \sum_i \left[ C_0 Q_i \left( \frac{1}{Q_i} \right)^2 + \frac{1}{2} \sum_{j \neq i} J_{ij}(r_{ij}) f_{cut}^{R_{coul}}(r_{ij}) Q_i Q_j \right]
\]

\[
E_{OO} = \sum_{i,j} \left[ C \exp \left( \frac{-r_{ij}}{\rho} \right) - D f_{cut}^{r_{OO}}(r_{ij}) \exp (B r_{ij}) \right]
\]

\[
E_{MO} = \sum_i E_{cov}^i + \sum_{j \neq i} A f_{cut}^{r_{MO}}(r_{ij}) \exp \left[ -p \left( \frac{r_{ij}}{r_0} - 1 \right) \right]
\]

where \( E_{tot} \) is the total potential energy of the system, \( E_{ES} \) is the electrostatic part of the total energy, \( E_{OO} \) is the interaction between oxygen atoms and \( E_{MO} \) is a short-range interaction between metal and oxygen atoms. This interactions depend on interatomic distance \( r_{ij} \) and/or the charge \( Q_i \) of atoms \( i \). Cut-off function enables smooth convergence to zero interaction.

The parameters appearing in the upper expressions are set in the ffield.SMTBQ.Syst file where Syst corresponds to the selected system (e.g. field.SMTBQ.Al2O3). Examples for TiO_2, Al_2O_3 are provided. A single pair_coeff command is used with the SMTBQ styles which provides the path to the potential file with parameters for needed elements. These are mapped to LAMMPS atom types by specifying additional arguments after the potential filename in the pair_coeff command. Note that atom type 1 must always correspond to oxygen atoms. As an example, to simulate a TiO_2 system, atom type 1 has to be oxygen and atom type 2 Ti. The following pair_coeff command should then be used:

```
pair_coeff * * PathToLammps/potentials/ffield.smtbq.TiO2 O Ti
```

The electrostatic part of the energy consists of two components

self-energy of atom \( i \) in the form of a second order charge dependent polynomial and a long-range Coulombic electrostatic interaction. The latter uses the wolf summation method described in Wolf, spherically truncated at a longer cutoff, \( R_{cut} \). The charge of each ion is modeled by an orbital Slater which depends on the principal quantum number \( n \) of the outer orbital shared by the ion.

Interaction between oxygen, \( E_{OO} \), consists of two parts, an attractive and a repulsive part. The attractive part is effective only at short range \((<r_{OO}^2)\). The attractive contribution was optimized to study surfaces reconstruction (e.g. SMTB-Q_2 in TiO_2) and is not necessary for oxide bulk modeling. The repulsive part is the Pauli interaction between the electron clouds of oxygen. The Pauli repulsion and the coulombic electrostatic interaction have same cut off value. In the ffield.SMTBQ.Syst, the keyword ‘buck’ allows to consider only the repulsive O-O interactions. The keyword ‘buckPlusAttr’ allows to consider the repulsive and the attractive O-O interactions.

The short-range interaction between metal-oxygen, \( E_{MO} \) is based on the second moment approximation of the density of states with a N-body potential for the band energy term, \( E_{cov} \), and a Born-Mayer type repulsive terms as indicated.
The energy band term is given by:

\[
E_{\text{cov}}^{i,j=M,O} = \left\{ \eta_i \left( \mu \xi^0 \right)^2 f_{\text{cut}}(r_{ij}) \left( \sum_{j(j=O,M)} e^{\exp[-2q(r_{ij} / r_0) - 1]} \right) \delta Q_i \left( 2n_0 / \eta_i - \delta Q_i \right) \right\}^{1/2}
\]

\[
\delta Q_i = |Q_F^i| - |Q_i|
\]

where \( \eta_i \) is the stoichiometry of atom \( i \), \( \delta Q_i \) is the charge delocalization of atom \( i \), compared to its formal charge \( Q_F^i \). \( n_0 \), the number of hybridized orbitals, is calculated with to the atomic orbitals shared \( d_i \) and the stoichiometry \( \eta_i \). \( r_{c1} \) and \( r_{c2} \) are the two cutoff radius around the fourth neighbors in the cutoff function.

In the formalism used here, \( \xi^0 \) is the energy parameter. \( \xi^0 \) is in tight-binding approximation the hopping integral between the hybridized orbitals of the cation and the anion. In the literature we find many ways to write the hopping integral depending on whether one takes the point of view of the anion or cation. These are equivalent vision. The correspondence between the two visions is explained in appendix A of the article in the SrTiO3 SMTB-Q-3 (parameter \( \beta \) shown in this article is in fact the \( \beta_O \)). To summarize the relationship between the hopping integral \( \xi^0 \) and the others, we have in an oxide \( C_nO_m \) the following relationship:

\[
\xi^0 = \frac{\xi_O}{m} = \frac{\xi_C}{n}
\]

\[
\frac{\beta_O}{\sqrt{m}} = \frac{\beta_C}{\sqrt{n}} = \xi^0 \sqrt{m} + \sqrt{n}
\]

Thus parameter \( \mu \), indicated above, is given by \( \mu = \frac{1}{2} \left( \sqrt{n} + \sqrt{m} \right) \).

The potential offers the possibility to consider the polarizability of the electron clouds of oxygen by changing the slater radius of the charge density around the oxygen atoms through the parameters \( r_{BB}, r_B \) and \( r_S \) in the ffield.SMTBQ.Syst. This change in radius is performed according to the method developed by E. Maras SMTB-Q.2. This method needs to determine the number of nearest neighbors around the oxygen. This calculation is based on first \( (r_{1n}) \) and second \( (r_{2n}) \) distances neighbors.

The SMTB-Q potential is a variable charge potential. The equilibrium charge on each atom is calculated by the electronegativity equalization (QEq) method. See Rick for further detail. One can adjust the frequency, the maximum number of iterative loop and the convergence of the equilibrium charge calculation. To obtain the energy conservation in NVE thermodynamic ensemble, we recommend to use a convergence parameter in the interval 10e-5 - 10e-6 eV.

The ffield.SMTBQ.Syst files are provided for few systems. They consist of nine parts and the lines beginning with ‘#’ are comments (note that the number of comment lines matter). The first sections are on the potential parameters and others are on the simulation options and might be modified. Keywords are character type and must be enclosed in quotation marks (‘’).

1) Number of different element in the oxide:
   - N_elem= 2 or 3
   - Divider line
2) Atomic parameters
   For the anion (oxygen):
   - Name of element (char) and stoichiometry in oxide
   - Formal charge and mass of element
   - Principal quantum number of outer orbital \( n \), electronegativity \( (\chi^0) \) and hardness \( (\beta^0) \)
   - Ionic radius parameters : max coordination number \( (\text{coordBB}=6 \text{ by default}) \), bulk coordination number \( (\text{coordB}) \), surface coordination number \( (\text{coordS}) \) and \( r_{BB}, r_B \) and \( r_S \) the slater radius for each coordination number. (note : If you don’t want to change the slater radius, use three identical radius values)
   - Number of orbital shared by the element in the oxide \( (d_i) \)
For each cations (metal):

- Name of element (char) and stoichiometry in oxide
- Formal charge and mass of element
- Number of electron in outer orbital \((ne)\), electronegativity \((\chi_0^i)\), hardness \((J_0^i)\) and \(r_{\text{Slater}}\) the slater radius for the cation.
- Number of orbitals shared by the elements in the oxide \((d_i)\)

3) Potential parameters:

- Keyword for element1, element2 and interaction potential (‘second_moment’ or ‘buck’ or ‘buckPlusAttr’) between element 1 and 2. If the potential is ‘second_moment’, specify ‘oxide’ or ‘metal’ for metal-oxygen or metal-metal interactions respectively.

  - Potential parameter:
    - If type of potential is ‘second_moment’ : \(A\) (eV), \(p\), \(\zeta_0^i\) (eV) and \(q\), \(r_{c1}\) (Å), \(r_{c2}\) (Å) and \(r_0\) (Å)
    - If type of potential is ‘buck’ : \(C\) (eV) and \(\rho(\text{Å})\)
    - If type of potential is ‘buckPlusAttr’ : \(C\) (eV) and \(\rho(\text{Å})\) \(D\) (eV), \(B\) (Å\(^{-1}\)), \(r_1^{OO}\) (Å) and \(r_2^{OO}\) (Å)

4) Tables parameters:

- Cutoff radius for the Coulomb interaction \((R_{\text{coul}})\)
- Starting radius \((r_{\text{min}} = 1, 18845\text{Å})\) and increments \((dr = 0.001\text{Å})\) for creating the potential table.

5) Rick model parameter:

- \(\text{Nevery}\) : parameter to set the frequency of the charge resolution. The charges are evaluated each \(\text{Nevery}\) time steps.
- Max number of iterative loop \((\text{loopmax})\) and convergence criterion \((\text{prec})\) in eV of the charge resolution

6) Coordination parameter:

- First \((r_{1n})\) and second \((r_{2n})\) neighbor distances in angstrom

7) Charge initialization mode:

- Keyword \((QInitMode)\) and initial oxygen charge \((Q_{\text{init}})\). If keyword = ‘true’, all oxygen charges are initially set equal to \(Q_{\text{init}}\). The charges on the cations are initially set in order to respect the neutrality of the box. If keyword = ‘false’, all atom charges are initially set equal to 0 if you use the \text{create_atoms} command or the charge specified in the file structure using \text{read_data} command.

8) Mode for the electronegativity equalization (Qeq)

- Keyword \((\text{mode})\) followed by:
  - QEqAll (one QEq group) \| no parameters
– QEqAllParallel (several QEq groups) | no parameters
– Surface | zlim (QEq only for z>zlim)

• Parameter if necessary
• Divider line

9) Verbose

• If you want the code to work in verbose mode or not : ‘true’ or ‘false’

• If you want to print or not in the file ‘Energy_component.txt’ the three main contributions to the energy of the system according to the description presented above : ‘true’ or ‘false’ and \( N_{Energy} \). This option writes to the file every \( N_{Energy} \) time steps. If the value is ‘false’ then \( N_{Energy} = 0 \). The file takes into account the possibility to have several QEq groups \( g \) then it writes: time step, number of atoms in group \( g \), electrostatic part of energy, \( E_{ES} \), the interaction between oxygen, \( E_{OO} \), and short range metal-oxygen interaction, \( E_{MO} \).

• If you want to print to the file ‘Electroneg_component.txt’ the electronegativity component \( \frac{\partial E_{tot}}{\partial Q_i} \) or not: ‘true’ or ‘false’ and \( N_{Electroneg} \). This option writes to the file every \( N_{Electroneg} \) time steps. If the value is ‘false’ then \( N_{Electroneg} = 0 \). The file consist of atom number \( i \), atom type (1 for oxygen and \# higher than 1 for metal), atom position: \( x \), \( y \) and \( z \), atomic charge of atom \( i \), electrostatic part of atom \( i \) electronegativity, covalent part of atom \( i \) electronegativity, the hopping integral of atom \( i \) \( (Z^2_β) \), and box electronegativity.

Note: This last option slows down the calculation dramatically. Use only with a single processor simulation.

20.202.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you needs to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.202.5 Restrictions

This pair style is part of the USER-SMTBQ package and is only enabled if LAMMPS is built with that package. See the Build package doc page for more info.

This potential requires using atom type 1 for oxygen and atom type higher than 1 for metal atoms.

This pair style requires the newton setting to be “on” for pair interactions.

The SMTB-Q potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units.
20.202.6 Citing this work

20.203 pair_style snap command

Accelerator Variants: snap/kk

20.203.1 Syntax

```
pair_style snap
```

20.203.2 Examples

```
pair_style snap
pair_coeff * * InP.snapcoeff InP.snapparam In In P P
```

20.203.3 Description

Pair style snap defines the spectral neighbor analysis potential (SNAP), a machine-learning interatomic potential (Thompson). Like the GAP framework of Bartok et al. (Bartok2010), SNAP uses bispectrum components to characterize the local neighborhood of each atom in a very general way. The mathematical definition of the bispectrum calculation and its derivatives w.r.t. atom positions is identical to that used by compute snap, which is used to fit SNAP potentials to ab initio energy, force, and stress data. In SNAP, the total energy is decomposed into a sum over atom energies. The energy of atom \( i \) is expressed as a weighted sum over bispectrum components.

\[
E_{\text{SNAP}}^i(B_1^i, ..., B_K^i) = \beta_0^i + \sum_{k=1}^{K} \beta_k^i B_k^i
\]

where \( B_k^i \) is the \( k \)-th bispectrum component of atom \( i \), and \( \beta_k^i \) is the corresponding linear coefficient that depends on \( \mu_i \), the SNAP element of atom \( i \). The number of bispectrum components used and their definitions depend on the value of \( \text{twojmax} \) and other parameters defined in the SNAP parameter file described below. The bispectrum calculation is described in more detail in compute sna/atom.

Note that unlike for other potentials, cutoffs for SNAP potentials are not set in the pair_style or pair_coeff command; they are specified in the SNAP potential files themselves.

Only a single pair_coeff command is used with the snap style which specifies a SNAP coefficient file followed by a SNAP parameter file and then \( N \) additional arguments specifying the mapping of SNAP elements to LAMMPS atom types, where \( N \) is the number of LAMMPS atom types:
• SNAP coefficient file
• SNAP parameter file
• N element names = mapping of SNAP elements to atom types

As an example, if a LAMMPS indium phosphide simulation has 4 atom types, with the first two being indium and
the third and fourth being phosphorous, the pair_coeff command would look like this:

```plaintext
pair_coeff * * snap InP.snapcoeff InP.snapparam In In P P
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The two filenames are for the coefficient
and parameter files, respectively. The two trailing ‘In’ arguments map LAMMPS atom types 1 and 2 to the SNAP ‘In’
element. The two trailing ‘P’ arguments map LAMMPS atom types 3 and 4 to the SNAP ‘P’ element.

If a SNAP mapping value is specified as NULL, the mapping is not performed. This can be used when a snap
potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other
potentials.

The name of the SNAP coefficient file usually ends in the “.snapcoeff” extension. It may contain coefficients for many
SNAP elements. The only requirement is that it contain at least those element names appearing in the LAMMPS
mapping list. The name of the SNAP parameter file usually ends in the “.snapparam” extension. It contains a small
number of parameters that define the overall form of the SNAP potential. See the pair_coeff doc page for alternate
ways to specify the path for these files.

Quite commonly, SNAP potentials are combined with one or more other LAMMPS pair styles using the hybrid/overlay
pair style. As an example, the SNAP tantalum potential provided in the LAMMPS potentials directory combines the
snap and zbl pair styles. It is invoked by the following commands:

```plaintext
variable zblcutinner equal 4
variable zblcutouter equal 4.8
variable zblz equal 73
pair_style hybrid/overlay &
zbl ${zblcutinner} ${zblcutouter} &

pair_coeff * * snap Ta06A.snapcoeff Ta06A.snapparam Ta

pair_coeff * * zbl 0.0
pair_coeff 1 1 zbl ${zblz} &
```

It is convenient to keep these commands in a separate file that can be inserted in any LAMMPS input script using the
include command.

The top of the SNAP coefficient file can contain any number of blank and comment lines (start with #), but follows a
strict format after that. The first non-blank non-comment line must contain two integers:

• nelem = Number of elements
• ncoeff = Number of coefficients

This is followed by one block for each of the nelem elements. The first line of each block contains three entries:

• Element symbol (text string)
• R = Element radius (distance units)
• w = Element weight (dimensionless)

This line is followed by ncoeff coefficients, one per line.

The SNAP parameter file can contain blank and comment lines (start with #) anywhere. Each non-blank non-comment
line must contain one keyword/value pair. The required keywords are rcutfac and twojmax. Optional keywords are
rfac0, rmin0, switchflag, bzeroflag, quadraticflag, chemflag, bnormflag, wselfallflag, and chunksize.

The default values for these keywords are
• \( rfac0 = 0.99363 \)
• \( rmin0 = 0.0 \)
• \( switchflag = 1 \)
• \( bzeroflag = 1 \)
• \( quadraticflag = 0 \)
• \( chemflag = 0 \)
• \( bnormflag = 0 \)
• \( wselfallflag = 0 \)
• \( chunksize = 2000 \)

If \( quadraticflag \) is set to 1, then the SNAP energy expression includes additional quadratic terms that have been shown to increase the overall accuracy of the potential without much increase in computational cost (Wood).

\[
E^{i}_{SNAP}(B^i) = \beta^\mu_i + \beta^\mu_i \cdot B_i + \frac{1}{2} B_i^T \cdot \alpha^\mu_i \cdot B_i
\]

where \( B_i \) is the \( K \)-vector of bispectrum components, \( \beta^\mu_i \) is the \( K \)-vector of linear coefficients for element \( \mu_i \), and \( \alpha^\mu_i \) is the symmetric \( K \) by \( K \) matrix of quadratic coefficients. The SNAP element file should contain \( K(K+1)/2 \) additional coefficients for each element, the upper-triangular elements of \( \alpha^\mu_i \).

If \( chemflag \) is set to 1, then the energy expression is written in terms of explicit multi-element bispectrum components indexed on ordered triplets of elements, which has been shown to increase the ability of the SNAP potential to capture energy differences in chemically complex systems, at the expense of a significant increase in computational cost (Cusentino).

\[
E^{i}_{SNAP}(B^i) = \beta^\mu_i + \sum_{\kappa,\lambda,\mu} \beta^{\kappa\lambda\mu}_{\mu_i} \cdot B^{\kappa\lambda\mu}_i
\]

where \( B^{\kappa\lambda\mu}_i \) is the \( K \)-vector of bispectrum components for neighbors of elements \( \kappa, \lambda, \) and \( \mu \) and \( \beta^{\kappa\lambda\mu}_{\mu_i} \) is the corresponding \( K \)-vector of linear coefficients for element \( \mu_i \). The SNAP element file should contain a total of \( K N_{\text{elem}}^3 \) coefficients for each of the \( N_{\text{elem}} \) elements.

The keyword \( chunksize \) is only applicable when using the pair style \textit{snap} with the KOKKOS package and is ignored otherwise. This keyword controls the number of atoms in each pass used to compute the bispectrum components and is used to avoid running out of memory. For example if there are 4000 atoms in the simulation and the \( chunksize \) is set to 2000, the bispectrum calculation will be broken up into two passes.

Detailed definitions for all the other keywords are given on the \textit{compute sna/atom} doc page.

\textbf{Note:} The previously used \textit{diagonalstyle} keyword was removed in 2019, since all known SNAP potentials use the default value of 3.
20.203.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs \( IJ \) and \( I \neq J \), where types \( I \) and \( J \) correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a pair_coeff command with \( I \neq J \) arguments for this style.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.203.5 Restrictions

This style is part of the SNAP package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

20.203.6 Related commands

compute sna/atom, compute snad/atom, compute snav/atom, compute snap

20.203.7 Default

none

20.204 pair_style soft command

Accelerator Variants: soft/gpu, soft/omp

20.204.1 Syntax

```
pair_style soft cutoff
```

- cutoff = global cutoff for soft interactions (distance units)

20.204.2 Examples

```
pair_style soft 1.0
pair_coeff  *  *  10.0
pair_coeff 1 1 10.0 3.0

pair_style soft 1.0
pair_coeff  *  *  0.0
variable prefactor equal ramp(0,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

20.204.3 Description

Style `soft` computes pairwise interactions with the formula

\[
E = A \left[ 1 + \cos \left( \frac{\pi r}{r_c} \right) \right] \quad r < r_c
\]

It is useful for pushing apart overlapping atoms, since it does not blow up as \( r \) goes to 0. \( A \) is a pre-factor that can be made to vary in time from the start to the end of the run (see discussion below), e.g. to start with a very soft potential and slowly harden the interactions over time. \( r_c \) is the cutoff. See the `fix nve/limit` command for another way to push apart overlapping atoms.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- \( A \) (energy units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global soft cutoff is used.

Note: The syntax for `pair_coeff` with a single \( A \) coeff is different in the current version of LAMMPS than in older versions which took two values, \( A_{\text{start}} \) and \( A_{\text{stop}} \), to ramp between them. This functionality is now available in a more general form through the `fix adapt` command, as explained below. Note that if you use an old input script and specify \( A_{\text{start}} \) and \( A_{\text{stop}} \) without a cutoff, then LAMMPS will interpret that as \( A \) and a cutoff, which is probably not what you want.

The `fix adapt` command can be used to vary \( A \) for one or more pair types over the course of a simulation, in which case `pair_coeff` settings for \( A \) must still be specified, but will be overridden. For example these commands will vary the prefactor \( A \) for all pairwise interactions from 0.0 at the beginning to 30.0 at the end of a run:
variable prefactor equal ramp(0,30)
fix 1 all adapt 1 pair soft a * v_prefactor

Note that a formula defined by an equal-style variable can use the current timestep, elapsed time in the current run, elapsed time since the beginning of a series of runs, as well as access other variables.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.204.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the A coefficient and cutoff distance for this pair style can be mixed. A is always mixed via a geometric rule. The cutoff is mixed according to the pair_modify mix value. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift option, since the pair interaction goes to 0.0 at the cutoff.

The pair_modify table and tail options are not relevant for this pair style.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.211 pair_style spin/dipole/cut command

20.212 pair_style spin/dipole/long command

20.212.1 Syntax

pair_style spin/dipole/cut cutoff
pair_style spin/dipole/long cutoff

• cutoff = global cutoff for magnetic dipole energy and forces (optional) (distance units)

20.212.2 Examples

pair_style spin/dipole/cut 10.0
pair_coeff * * 10.0
pair_coeff 2 3 8.0

pair_style spin/dipole/long 9.0
pair_coeff * * 10.0
pair_coeff 2 3 6.0
20.212.3 Description

Style spin/dipole/cut computes a short-range dipole-dipole interaction between pairs of magnetic particles that each have a magnetic spin. The magnetic dipole-dipole interactions are computed by the following formulas for the magnetic energy, magnetic precession vector omega and mechanical force between particles I and J.

\[
H_{\text{long}} = -\frac{\mu_0 (\mu_B)^2}{4\pi} \sum_{i,j,i\neq j}^N \frac{g_i g_j}{r_{ij}^3} \left( 3 (\vec{e}_{ij} \cdot \vec{s}_i) (\vec{e}_{ij} \cdot \vec{s}_j) - \vec{s}_i \cdot \vec{s}_j \right)
\]

\[
\omega_i = \frac{\mu_0 (\mu_B)^2}{4\pi \hbar} \sum_j \frac{g_i g_j}{r_{ij}^3} \left( 3 (\vec{e}_{ij} \cdot \vec{s}_j) \vec{e}_{ij} - \vec{s}_j \right)
\]

\[
\mathbf{F}_i = \frac{3 \mu_0 (\mu_B)^2}{4\pi} \sum_j \frac{g_i g_j}{r_{ij}} \left[ \left( \vec{s}_i \cdot \vec{s}_j \right) - 5 (\vec{e}_{ij} \cdot \vec{s}_j)(\vec{e}_{ij} \cdot \vec{s}_i) \right] \vec{e}_{ij} + \left( (\vec{e}_{ij} \cdot \vec{s}_i)\vec{s}_j + (\vec{e}_{ij} \cdot \vec{s}_j)\vec{s}_i \right)
\]

where \( \vec{s}_i \) and \( \vec{s}_j \) are the spin on two magnetic particles, \( r \) is their separation distance, and the vector \( \vec{e}_{ij} = \frac{\vec{r}_i - \vec{r}_j}{|\vec{r}_i - \vec{r}_j|} \) is the direction vector between the two particles.

Style spin/dipole/long computes long-range magnetic dipole-dipole interaction. A kspace_style must be defined to use this pair style. Currently, kspace_style ewald/dipole/spin and kspace_style pppm/dipole/spin support long-range magnetic dipole-dipole interactions.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

20.212.4 Restrictions

The spin/dipole/cut and spin/dipole/long styles are part of the SPIN package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Using dipole/spin pair styles with electron units is not currently supported.

20.212.5 Related commands

pair_coeff, kspace_style fix nve/spin

none
20.213 pair_style spin/dmi command

20.213.1 Syntax

```
pair_style spin/dmi cutoff
```

- cutoff = global cutoff pair (distance in metal units)

20.213.2 Examples

```
pair_style spin/dmi 4.0
pair_coeff * * dmi 2.6 0.001 1.0 0.0 0.0
pair_coeff 1 2 dmi 4.0 0.00109 0.0 0.0 1.0
```

20.213.3 Description

Style `spin/dmi` computes the Dzyaloshinskii-Moriya (DM) interaction between pairs of magnetic spins. According to the expression reported in (Rohart), one has the following DM energy:

\[ H_{dm} = \sum_{i, j = 1, i \neq j}^{N} \left( \vec{e}_{ij} \times \vec{D} \right) \cdot (\vec{s}_i \times \vec{s}_j), \]

where \( \vec{s}_i \) and \( \vec{s}_j \) are two neighboring magnetic spins of two particles, \( \vec{e}_{ij} = \frac{r_i - r_j}{|r_i - r_j|} \) is the unit vector between sites \( i \) and \( j \), and \( \vec{D} \) is the DM vector defining the intensity (in eV) and the direction of the interaction.

In (Rohart), \( \vec{D} \) is defined as the direction normal to the film oriented from the high spin-orbit layer to the magnetic ultra-thin film.

The application of a spin-lattice Poisson bracket to this energy (as described in (Tranchida)) allows to derive a magnetic torque \( \vec{\omega} \), and a mechanical force \( \vec{F} \) (for spin-lattice calculations only) for each magnetic particle \( i \):

\[ \vec{\omega}_i = -\frac{1}{\hbar} \sum_{j}^{N_{\text{Neigh}}} \vec{s}_j \times (\vec{e}_{ij} \times \vec{D}) \quad \text{and} \quad \vec{F}_i = -\sum_{j}^{N_{\text{Neigh}}} \frac{1}{r_{ij}} \vec{D} \times (\vec{s}_i \times \vec{s}_j) \]

More details about the derivation of these torques/forces are reported in (Tranchida).

For the `spin/dmi` pair style, the following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, and set in the following order:

- \( r_c \) (distance units)
- \( |\vec{D}| \) (energy units)
- \( D_x, D_y, D_z \) (direction of \( \vec{D} \))

Note that \( r_c \) is the radius cutoff of the considered DM interaction, \( |\vec{D}| \) is the norm of the DM vector (in eV), and \( D_x, D_y \) and \( D_z \) define its direction.

None of those coefficients is optional. If not specified, the `spin/dmi` pair style cannot be used.
20.213.4 Restrictions

All the pair/spin styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom_style “spin” was declared. See the Build package doc page for more info.

20.213.5 Related commands

atom_style spin, pair_coeff, pair_eam

20.213.6 Default

none

20.214 pair_style spin/exchange command

20.214.1 Syntax

```
pair_style spin/exchange cutoff
```

- cutoff = global cutoff pair (distance in metal units)

20.214.2 Examples

```
pair_style spin/exchange 4.0
pair_coeff * * exchange 4.0 0.0446928 0.003496 1.4885
pair_coeff 1 2 exchange 6.0 -0.01575 0.0 1.965
```

20.214.3 Description

Style spin/exchange computes the exchange interaction between pairs of magnetic spins:

\[ H_{ex} = -\sum_{i,j}^N J_{ij}(r_{ij}) \mathbf{s}_i \cdot \mathbf{s}_j \]

where \( \mathbf{s}_i \) and \( \mathbf{s}_j \) are two neighboring magnetic spins of two particles, \( r_{ij} = |\mathbf{r}_i - \mathbf{r}_j| \) is the inter-atomic distance between the two particles. The summation is over pairs of nearest neighbors. \( J(r_{ij}) \) is a function defining the intensity and the sign of the exchange interaction for different neighboring shells. This function is defined as:

\[ J(r_{ij}) = 4a \left( \frac{r_{ij}}{d} \right)^2 \left( 1 - b \left( \frac{r_{ij}}{d} \right)^2 \right) e^{-\left( \frac{r_{ij}}{d} \right)^2} \Theta(R_c - r_{ij}) \]

where \( a, b \) and \( d \) are the three constant coefficients defined in the associated “pair_coeff” command, and \( R_c \) is the radius cutoff associated to the pair interaction (see below for more explanations).
The coefficients $a$, $b$, and $d$ need to be fitted so that the function above matches with the value of the exchange interaction for the $N$ neighbor shells taken into account. Examples and more explanations about this function and its parameterization are reported in [Tranchida].

From this exchange interaction, each spin $i$ will be submitted to a magnetic torque $\vec{\omega}$, and its associated atom can be submitted to a force $\vec{F}$ for spin-lattice calculations (see fix nve/spin), such as:

$$\vec{\omega}_i = \frac{1}{\hbar} \sum_j^{N_{\text{Neigh}}} J(r_{ij}) \vec{s}_j \quad \text{and} \quad \vec{F}_i = \sum_j^{N_{\text{Neigh}}} \frac{\partial J(r_{ij})}{\partial r_{ij}} (\vec{s}_i \cdot \vec{s}_j) \hat{e}_{ij}$$

with $\hbar$ the Planck constant (in metal units), and $\hat{e}_{ij} = \frac{\vec{r}_i - \vec{r}_j}{|\vec{r}_i - \vec{r}_j|}$ the unit vector between sites $i$ and $j$.

More details about the derivation of these torques/forces are reported in [Tranchida].

For the $\text{spin/exchange}$ pair style, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, and set in the following order:

- $R_c$ (distance units)
- $a$ (energy units)
- $b$ (adim parameter)
- $d$ (distance units)

Note that $R_c$ is the radius cutoff of the considered exchange interaction, and $a$, $b$ and $d$ are the three coefficients performing the parameterization of the function $J(r_{ij})$ defined above.

None of those coefficients is optional. If not specified, the $\text{spin/exchange}$ pair style cannot be used.

---

### 20.214.4 Restrictions

All the $\text{pair/spin}$ styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom_style “spin” was declared. See the [Build package] doc page for more info.

pair_coeff * * magelec 4.5 0.00109 1.0 1.0 1.0
```

20.215.3 Description

Style `spin/me` computes a magneto-electric interaction between pairs of magnetic spins. According to the derivation reported in *(Katsura)*, this interaction is defined as:

\[
\vec{\omega}_i = -\frac{1}{\hbar} \sum_j^{\text{Neigh}} \vec{s}_j \times \vec{D}(r_{ij})
\]

\[
\vec{F}_i = -\sum_j^{\text{Neigh}} \frac{\partial D(r_{ij})}{\partial r_{ij}} (\vec{s}_i \times \vec{s}_j) \cdot \vec{r}_{ij}
\]

where \(\vec{s}_i\) and \(\vec{s}_j\) are neighboring magnetic spins of two particles.

From this magneto-electric interaction, each spin \(i\) will be submitted to a magnetic torque \(\omega\), and its associated atom can be submitted to a force \(F\) for spin-lattice calculations (see `fix nve/spin`), such as:

\[
\vec{F}_i = -\sum_j^{\text{Neighbor}} (\vec{s}_i \times \vec{s}_j) \times \vec{E}
\]

\[
\vec{\omega}_i = -\frac{1}{\hbar} \sum_j^{\text{Neighbor}} \vec{s}_j \times \left(\vec{E} \times \vec{r}_{ij}\right)
\]

with \(\hbar\) the Planck constant (in metal units) and \(\vec{E}\) an electric polarization vector. The norm and direction of \(\vec{E}\) are giving the intensity and the direction of a screened dielectric atomic polarization (in eV).

More details about the derivation of these torques/forces are reported in *(Tranchida)*.

20.215.4 Restrictions

All the `pair/spin` styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom_style “spin” was declared. See the `Build package` doc page for more info.
20.215.5 Related commands

atom_style spin, pair_coeff, pair_style spin/exchange, pair_eam.

20.215.6 Default

none

20.216 pair_style spin/neel command

20.216.1 Syntax

```
pair_style spin/neel cutoff
```

- cutoff = global cutoff pair (distance in metal units)

20.216.2 Examples

```
pair_style spin/neel 4.0
pair_coeff * * neel 4.0 0.0048 0.234 1.168 2.6905 0.705 0.652
pair_coeff 1 2 neel 4.0 0.0048 0.234 1.168 0.0 0.0 1.0
```

20.216.3 Description

Style `spin/neel` computes the Neel pair anisotropy model between pairs of magnetic spins:

\[
\mathcal{H}_{\text{Neel}} = - \sum_{i,j=1,i\neq j}^N g_1(r_{ij}) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_i)(\mathbf{e}_{ij} \cdot \mathbf{s}_j) - \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{3} \right) + q_1(r_{ij}) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_i)^2 - \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{3} \right) + q_2(r_{ij}) \left( (\mathbf{e}_{ij} \cdot \mathbf{s}_i)^2 + (\mathbf{e}_{ij} \cdot \mathbf{s}_j)^2 \right)
\]

where \( \mathbf{s}_i \) and \( \mathbf{s}_j \) are two neighboring magnetic spins of two particles, \( r_{ij} = |\mathbf{r}_i - \mathbf{r}_j| \) is the inter-atomic distance between the two particles, \( \mathbf{e}_{ij} = \frac{\mathbf{r}_i - \mathbf{r}_j}{|\mathbf{r}_i - \mathbf{r}_j|} \) is their normalized separation vector and \( g_1, q_1 \) and \( q_2 \) are three functions defining the intensity of the dipolar and quadrupolar contributions, with:

\[
g_1(r_{ij}) = g(r_{ij}) + \frac{12}{35} q(r_{ij}) \\
q_1(r_{ij}) = \frac{9}{5} q(r_{ij}) \\
q_2(r_{ij}) = -\frac{2}{5} q(r_{ij})
\]

With the functions \( g(r_{ij}) \) and \( q(r_{ij}) \) defined and fitted according to the same Bethe-Slater function used to fit the exchange interaction:

\[
J(r_{ij}) = 4a \left( \frac{r_{ij}}{d} \right)^2 \left( 1 - b \left( \frac{r_{ij}}{d} \right)^2 \right) e^{-\left( \frac{r_{ij}}{d} \right)^2} \Theta(R_c - r_{ij})
\]

2000  Chapter 20.  Pair Styles
where $a$, $b$ and $d$ are the three constant coefficients defined in the associated “pair_coeff” command.

The coefficients $a$, $b$, and $d$ need to be fitted so that the function above matches with the values of the magneto-elastic constant of the materials at stake.

Examples and more explanations about this function and its parameterization are reported in (Tranchida). More examples of parameterization will be provided in future work.

From this DM interaction, each spin $i$ will be submitted to a magnetic torque $\omega$ and its associated atom to a force $F$ (for spin-lattice calculations only).

More details about the derivation of these torques/forces are reported in (Tranchida).

### 20.216.4 Restrictions

```

20.217.3 Description

Style *srp* computes a soft segmental repulsive potential (SRP) that acts between pairs of bonds. This potential is useful for preventing bonds from passing through one another when a soft non-bonded potential acts between beads in, for example, DPD polymer chains. An example input script that uses this command is provided in examples/USER/srp.

Bonds of specified type *btype* interact with one another through a bond-pairwise potential, such that the force on bond *i* due to bond *j* is as follows

\[ F_{ij}^{\text{SRP}} = C (1 - r / r_c) \hat{r}_{ij} \quad r < r_c \]

where \( r \) and \( \hat{r}_{ij} \) are the distance and unit vector between the two bonds. Note that *btype* can be specified as an asterisk “*”, which case the interaction is applied to all bond types. The *mid* option computes \( r \) and \( \hat{r}_{ij} \) from the midpoint distance between bonds. The *min* option computes \( r \) and \( \hat{r}_{ij} \) from the minimum distance between bonds. The force acting on a bond is mapped onto the two bond atoms according to the lever rule,

\[ F_{i1}^{\text{SRP}} = F_{ij}^{\text{SRP}} (L) \]
\[ F_{i2}^{\text{SRP}} = F_{ij}^{\text{SRP}} (1 - L) \]

where \( L \) is the normalized distance from the atom to the point of closest approach of bond *i* and *j*. The *mid* option takes \( L \) as 0.5 for each interaction as described in \( \text{(Sirk)} \).

The following coefficients must be defined via the `pair_coeff` command as in the examples above, or in the data file or restart file read by the `read_data` or `read_restart` commands:

- \( C \) (force units)
- \( r_c \) (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

**Note:** Pair style *srp* considers each bond of type *btype* to be a fictitious “particle” of type *bptype*, where *bptype* is either the largest atom type in the system, or the type set by the *bptype* flag. Any actual existing particles with this atom type will be deleted at the beginning of a run. This means you must specify the number of types in your system accordingly; usually to be one larger than what would normally be the case, e.g. via the `create_box` or by changing the header in your *data file*. The fictitious “bond particles” are inserted at the beginning of the run, and serve as placeholders that define the position of the bonds. This allows neighbor lists to be constructed and pairwise interactions to be computed in almost the same way as is done for actual particles. Because bonds interact only with
other bonds, \textit{pair\_style hybrid} should be used to turn off interactions between atom type \textit{bptype} and all other types of atoms. An error will be flagged if \textit{pair\_style hybrid} is not used.

The optional \textit{exclude} keyword determines if forces are computed between first neighbor (directly connected) bonds. For a setting of \textit{no}, first neighbor forces are computed; for \textit{yes} they are not computed. A setting of \textit{no} cannot be used with the \textit{min} option for distance calculation because the minimum distance between directly connected bonds is zero.

Pair style \textit{srp} turns off normalization of thermodynamic properties by particle number, as if the command \textit{thermo\_modify norm no} had been issued.

The pairwise energy associated with style \textit{srp} is shifted to be zero at the cutoff distance $r_c$.

### 20.217.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing.

This pair style does not support the \textit{pair\_modify} shift option for the energy of the pair interaction. Note that as discussed above, the energy term is already shifted to be 0.0 at the cutoff distance $r_c$.

The \textit{pair\_modify} table option is not relevant for this pair style.

This pair style does not support the \textit{pair\_modify} tail option for adding long-range tail corrections to energy and pressure.

This pair style writes global and per-atom information to binary restart files. Pair \textit{srp} should be used with \textit{pair\_style hybrid}, thus the \textit{pair\_coeff} commands need to be specified in the input script when reading a restart file.

This pair style can only be used via the \textit{pair} keyword of the \textit{run\_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

### 20.217.5 Restrictions

This pair style is part of the USER-MISC package. It is only enabled if LAMMPS was built with that package. See the Making LAMMPS section for more info.

This pair style must be used with \textit{pair\_style hybrid}.

This pair style requires the \textit{newton} command to be \textit{on} for non-bonded interactions.

This pair style is not compatible with \textit{rigid body integrators}.

20.218 pair_style sw command

Accelerator Variants: sw/gpu, sw/intel, sw/kk, sw/omp

20.218.1 Syntax

```
pair_style sw
```

20.218.2 Examples

```
pair_style sw
pair_coeff * * si.sw Si
pair_coeff * * GaN.sw Ga N Ga
```

20.218.3 Description

The `sw` style computes a 3-body Stillinger-Weber potential for the energy E of a system of atoms as

\[
E = \sum_i \sum_{j>i} \phi_2(r_{ij}) + \sum_i \sum_{j<i} \sum_{k>j} \phi_3(r_{ij}, r_{ik}, \theta_{ijk})
\]

\[
\phi_2(r_{ij}) = A_{ij} \epsilon_{ij} \left[ \frac{B_{ij} (\sigma_{ij})^{p_{ij}} - (\sigma_{ij})^{q_{ij}}}{\sigma_{ij} r_{ij} - a_{ij} \sigma_{ij}} \right] \exp \left( \frac{\sigma_{ij}}{\sigma_{ij} r_{ij} - a_{ij} \sigma_{ij}} \right)
\]

\[
\phi_3(r_{ij}, r_{ik}, \theta_{ijk}) = \lambda_{ijk} \epsilon_{ijk} \left[ \cos \theta_{ijk} - \cos \theta_{0ijk} \right] \exp \left( \frac{\gamma_{ijk} \sigma_{ij}}{r_{ij} - a_{ij} \sigma_{ij}} \right) \exp \left( \frac{\gamma_{ijk} \sigma_{ik}}{r_{ik} - a_{ik} \sigma_{ik}} \right)
\]

where \( \phi_2 \) is a two-body term and \( \phi_3 \) is a three-body term. The summations in the formula are over all neighbors J and K of atom I within a cutoff distance \( a \).

Only a single pair_coeff command is used with the `sw` style which specifies a Stillinger-Weber potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of SW elements to atom types

See the `pair_coeff` doc page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.sw has Stillinger-Weber values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * SiC.sw Si Si Si C
```
The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the SW file. The final C argument maps LAMMPS atom type 4 to the C element in the SW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a sw potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Stillinger-Weber files in the potentials directory of the LAMMPS distribution have a "sw" suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- a
- $\lambda$
- $\gamma$
- $\cos \theta_0$
- A
- B
- p
- q
- tol

The A, B, p, and q parameters are used only for two-body interactions. The $\lambda$ and $\cos \theta_0$ parameters are used only for three-body interactions. The $\epsilon$, $\sigma$, and a parameters are used for both two-body and three-body interactions. $\gamma$ is used only in the three-body interactions, but is defined for pairs of atoms. The non-annotated parameters are unitless.

LAMMPS introduces an additional performance-optimization parameter tol that is used for both two-body and three-body interactions. In the Stillinger-Weber potential, the interaction energies become negligibly small at atomic separations substantially less than the theoretical cutoff distances. LAMMPS therefore defines a virtual cutoff distance based on a user defined tolerance tol. The use of the virtual cutoff distance in constructing atom neighbor lists can significantly reduce the neighbor list sizes and therefore the computational cost. LAMMPS provides a tol value for each of the three-body entries so that they can be separately controlled. If tol = 0.0, then the standard Stillinger-Weber cutoff is used.

The Stillinger-Weber potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSIi, CSIc, CCSi, CCC), that specify SW parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction. Thus an entry for SiCC means a Si atom with 2 C atoms as neighbors. The parameter values used for the two-body interaction come from the entry where the second and third elements are the same. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry. The three-body parameters can in principle be specific to the three elements of the configuration. In the literature, however, the three-body parameters are usually defined by simple formulas involving two sets of pair-wise parameters, corresponding to the ij and ik pairs, where i is the center atom. The user must ensure
that the correct combining rule is used to calculate the values of the three-body parameters for alloys. Note also that the function $\phi_3$ contains two exponential screening factors with parameter values from the ij pair and ik pairs. So $\phi_3$ for a C atom bonded to a Si atom and a second C atom will depend on the three-body parameters for the CSiC entry, and also on the two-body parameters for the CCC and CSiSi entries. Since the order of the two neighbors is arbitrary, the three-body parameters for entries CSiC and CCSi should be the same. Similarly, the two-body parameters for entries SiCC and CSiSi should also be the same. The parameters used only for two-body interactions (A, B, p, and q) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired. This is also true for the parameters in $\phi_3$ that are taken from the ij and ik pairs ($\sigma, a, \gamma$).

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

When using the USER-INTEL package with this style, there is an additional 5 to 10 percent performance improvement when the Stillinger-Weber parameters p and q are set to 4 and 0 respectively. These parameters are common for modeling silicon and water.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.218.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the `pair_modify shift`, `table`, and `tail` options.

This pair style does not write its information to `binary restart files`, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 20.218.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

The Stillinger-Weber potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the SW potential with any LAMMPS units, but you would need to create your own SW potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.
20.218.6 Related commands

pair_coeff

pair_coeff * 3 morse.table ENTRY1
pair_coeff * 3 morse.table ENTRY1 7.0
```

20.219.3 Description

Style table creates interpolation tables from potential energy and force values listed in a file(s) as a function of distance. When performing dynamics or minimization, the interpolation tables are used to evaluate energy and forces for pairwise interactions between particles, similar to how analytic formulas are used for other pair styles.

The interpolation tables are created as a pre-computation by fitting cubic splines to the file values and interpolating energy and force values at each of \( N \) distances. During a simulation, the tables are used to interpolate energy and force values as needed for each pair of particles separated by a distance \( R \). The interpolation is done in one of 4 styles: lookup, linear, spline, or bitmap.

For the lookup style, the distance \( R \) is used to find the nearest table entry, which is the energy or force.

For the linear style, the distance \( R \) is used to find the 2 surrounding table values from which an energy or force is computed by linear interpolation.
For the *spline* style, cubic spline coefficients are computed and stored for each of the \( N \) values in the table, one set of splines for energy, another for force. Note that these splines are different than the ones used to pre-compute the \( N \) values. Those splines were fit to the \( N_{file} \) values in the tabulated file, where often \( N_{file} < N \). The distance \( R \) is used to find the appropriate set of spline coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

For the *bitmap* style, the specified \( N \) is used to create interpolation tables that are \( 2^N \) in length. The distance \( R \) is used to index into the table via a fast bit-mapping technique due to (Wolff), and a linear interpolation is performed between adjacent table values.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above.

- **filename**
- **keyword**
- **cutoff (distance units)**

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

If your tabulated potential(s) are designed to be used as the short-range part of one of the long-range solvers specified by the `kspace_style` command, then you must use one or more of the optional keywords listed above for the `pair_style` command. These are `ewald` or `pppm` or `msm` or `dispersion` or `tip4p`. This is so LAMMPS can insure the short-range potential and long-range solver are compatible with each other, as it does for other short-range pair styles, such as `pair_style lj/cut/coul/long`. Note that it is up to you to insure the tabulated values for each pair of atom types has the correct functional form to be compatible with the matching long-range solver.

Here are some guidelines for using the `pair_style` table command to best effect:

- **Vary the number of table points; you may need to use more than you think to get good resolution.**
- **Always use the `pair_write` command to produce a plot of what the final interpolated potential looks like.** This can show up interpolation “features” you may not like.
- **Start with the linear style; it’s the style least likely to have problems.**
- **Use \( N \) in the `pair_style` command equal to the “\( N \)” in the tabulation file, and use the “RSQ” or “BITMAP” parameter, so additional interpolation is not needed. See discussion below.**
- **Make sure that your tabulated forces and tabulated energies are consistent (\( dE/dr = -F \)) over the entire range of \( r \) values. LAMMPS will warn if this is not the case.**
- **Use as large an inner cutoff as possible.** This avoids fitting splines to very steep parts of the potential.

The format of a tabulated file has an (optional) header followed by a series of one or more sections, defined as follows (without the parenthesized comments). The header must start with a `#` character and the DATE: and UNITS: tags will be parsed and used:

```plaintext
# DATE: 2020-06-10  UNITS: real  CONTRIBUTOR: ... (header line)
# Morse potential for Fe  (one or more comment or blank lines)
MORSE_FE  (keyword is first text on line)
N 500 R 1.0 10.0  (N, R, RSQ, BITMAP, FPRIME parameters)
(blank)
```

(continues on next page)
A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the pair_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the pair_style table command. Let Ntable = N in the pair_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate energy and force values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and force for individual pair distances. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile, and use the “RSQ” or “BITMAP” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” or “BITMAP” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in r uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values rlo and rhi. If specified, the distance associated with each energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The distance values in the table file are ignored in this case. For “R”, distances uniformly spaced between rlo and rhi are computed; for “RSQ”, squared distances uniformly spaced between rlo*rlo and rhi*rhi are computed.

Note: If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the distance value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning energy/force values to a different distance, which is probably not what you want. LAMMPS will warn if this is occurring.

If used, the parameter “BITMAP” is also followed by 2 values rlo and rhi. These values, along with the “N” value determine the ordering of the N lines that follow and what distance is associated with each. This ordering is complex, so it is not documented here, since this file is typically produced by the pair_write command with its bitmap option. When the table is in BITMAP format, the “N” parameter in the file must be equal to 2^M where M is the value specified in the pair_style command. Also, a cutoff parameter cannot be used as an optional third argument in the pair_coeff command; the entire table extent as specified in the file must be used.

If used, the parameter “FPRIME” is followed by 2 values fplo and fphi which are the derivative of the force at the innermost and outermost distances listed in the table. These values are needed by the spline construction routines. If not specified by the “FPRIME” parameter, they are estimated (less accurately) by the first 2 and last 2 force values in the table. This parameter is not used by BITMAP tables.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The r values must increase from one line to the next (unless the BITMAP parameter is specified).

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.
Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

### 20.219.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

The *pair_modify* shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair_style table” command to *binary restart files*, so a pair_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, *pair_coeff* commands do need to be specified in the restart input script.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

### 20.219.5 Restrictions

none

### 20.219.6 Related commands

20.220 pair_style table/rx command

Accelerator Variants: table/rx/kk

20.220.1 Syntax

```
pair_style table style N ...
```

- style = lookup or linear or spline or bitmap = method of interpolation
- N = use N values in lookup, linear, spline tables
- weighting = fractional or molecular (optional)

20.220.2 Examples

```
pair_style table/rx linear 1000
pair_style table/rx linear 1000 fractional
pair_style table/rx linear 1000 molecular
pair_coeff * * rxn.table ENTRY1 h2o h2o 10.0
pair_coeff * * rxn.table ENTRY1 1fluid 1fluid 10.0
pair_coeff * 3 rxn.table ENTRY1 h2o no2 10.0
```

20.220.3 Description

Style table/rx is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of \( m \) species whose reaction rate kinetics are determined from a set of \( n \) reaction rate equations through the fix rx command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. Style table/rx creates interpolation tables of length \( N \) from pair potential and force values listed in a file(s) as a function of distance. The files are read by the pair_coeff command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and force values at each of \( N \) distances. During a simulation, these tables are used to interpolate energy and force values as needed. The interpolation is done in one of 4 styles: lookup, linear, spline, or bitmap.

For the lookup style, the distance between 2 atoms is used to find the nearest table entry, which is the energy or force.

For the linear style, the pair distance is used to find 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the spline style, a cubic spline coefficients are computed and stored at each of the \( N \) values in the table. The pair distance is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

For the bitmap style, the \( N \) means to create interpolation tables that are \( 2^N \) in length. The pair distance is used to index into the table via a fast bit-mapping technique (Wolff) and a linear interpolation is performed between adjacent table values.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above.

- filename
- keyword
- species1
• species2
• cutoff (distance units)

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The species tags define the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the `fix rx` command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the `fractional` or `molecular` weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).

Here are some guidelines for using the pair_style table/rx command to best effect:

- Vary the number of table points; you may need to use more than you think to get good resolution.
- Always use the `pair_write` command to produce a plot of what the final interpolated potential looks like. This can show up interpolation “features” you may not like.
- Start with the linear style; it’s the style least likely to have problems.
- Use N in the pair_style command equal to the “N” in the tabulation file, and use the “RSQ” or “BITMAP” parameter, so additional interpolation is not needed. See discussion below.
- Make sure that your tabulated forces and tabulated energies are consistent (dE/dr = -F) along the entire range of r values.
- Use as large an inner cutoff as possible. This avoids fitting splines to very steep parts of the potential.

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

```plaintext
# Morse potential for Fe    (one or more comment or blank lines)
MORSE_FE                   (keyword is first text on line)
N 500 R 1.0 10.0           (N, R, RSQ, BITMAP, FPRIME parameters)
(blank)
1 1.0 25.5 102.34          (index, r, energy, force)
2 1.02 23.4 98.5
...
500 10.0 0.001 0.003
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the pair_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the pair_style table/rx command. Let Ntable = N in the pair_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and force values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and force for
individual pair distances. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile, and use the “RSQ” or “BITMAP” parameter. The internal table abscissa is RSQ (separation distance squared).

All other parameters are optional. If “R” or “RSQ” or “BITMAP” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in \( r \) uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values \( rlo \) and \( rhi \). If specified, the distance associated with each energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The distance values in the table file are ignored in this case. For “R”, distances uniformly spaced between \( rlo \) and \( rhi \) are computed; for “RSQ”, squared distances uniformly spaced between \( rlo^2rlo \) and \( rhi*rhi \) are computed.

If used, the parameter “BITMAP” is also followed by 2 values \( rlo \) and \( rhi \). These values, along with the “N” value determine the ordering of the N lines that follow and what distance is associated with each. This ordering is complex, so it is not documented here, since this file is typically produced by the \texttt{pair_write} command with its \textit{bitmap} option. When the table is in BITMAP format, the “N” parameter in the file must be equal to \( 2^M \) where \( M \) is the value specified in the pair\_style command. Also, a cutoff parameter cannot be used as an optional third argument in the pair\_coeff command; the entire table extent as specified in the file must be used.

If used, the parameter “FPRIME” is followed by 2 values \( fplo \) and \( fphi \) which are the derivative of the force at the innermost and outermost distances listed in the table. These values are needed by the spline construction routines. If not specified by the “FPRIME” parameter, they are estimated (less accurately) by the first 2 and last 2 force values in the table. This parameter is not used by BITMAP tables.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is \( r \) (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The \( r \) values must increase from one line to the next (unless the BITMAP parameter is specified).

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

### 20.220.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

The \texttt{pair_modify} shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair\_style table/rx” command to binary restart files, so a pair\_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, pair\_coeff commands do need to be specified in the restart input script.

This pair style can only be used via the \texttt{pair} keyword of the \texttt{run\_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Speed package} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} doc page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

20.220.5 Restrictions

This command is part of the USER-DPD package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

Accelerator Variants: `tersoff/gpu`, `tersoff/intel`, `tersoff/kk`, `tersoff/omp`

20.222 `pair_style tersoff/table` command

Accelerator Variants: `tersoff/table/omp`

20.222.1 Syntax

```
pair_style style

• style = tersoff or tersoff/table or tersoff/gpu or tersoff/omp or tersoff/table/omp
```

20.222.2 Examples

```
pair_style tersoff
pair_coeff * * Si.tersoff Si
pair_coeff * * SiC.tersoff Si C Si

pair_style tersoff/table
pair_coeff * * SiGe.tersoff Si(D)
```
20.222.3 Description

The *tersoff* style computes a 3-body Tersoff potential (*Tersoff_I*) for the energy $E$ of a system of atoms as

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = f_C(r_{ij}) \left[ f_R(r_{ij}) + b_{ij} f_A(r_{ij}) \right]$$

$$f_C(r) = \begin{cases} 
\frac{1}{2} - \frac{1}{2} \sin \left( \frac{\pi}{2} \frac{r-R}{D} \right) & : r < R - D \\
\frac{1}{2} - \frac{1}{2} \sin \left( \frac{\pi}{2} \frac{r-R}{D} \right) & : R - D < r < R + D \\
0 & : r > R + D
\end{cases}$$

$$f_R(r) = A \exp(-\lambda_1 r)$$

$$f_A(r) = -B \exp(-\lambda_2 r)$$

$$b_{ij} = (1 + \beta^n \zeta_{ij}^n)^{-\frac{1}{n}}$$

$$\zeta_{ij} = \sum_{k \neq i,j} f_C(r_{ik}) g(\theta_{ijk}) \exp \left[ \lambda_3 m (r_{ij} - r_{ik})^m \right]$$

$$g(\theta) = \gamma_{ijk} \left( 1 + \frac{c^2}{d^2} - \frac{c^2}{d^2 + (\cos \theta - \cos \theta_{0})^2} \right)$$

where $f_R$ is a two-body term and $f_A$ includes three-body interactions. The summations in the formula are over all neighbors J and K of atom I within a cutoff distance = $R + D$.

The *tersoff/table* style uses tabulated forms for the two-body, environment and angular functions. Linear interpolation is performed between adjacent table entries. The table length is chosen to be accurate within 10^-6 with respect to the *tersoff* style energy. The *tersoff/table* should give better performance in terms of speed.

Only a single pair_coeff command is used with the *tersoff* style which specifies a Tersoff potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of Tersoff elements to atom types

See the *pair_coeff* doc page for alternate ways to specify the path for the potential file.

As an example, imagine the SiC.tersoff file has Tersoff values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * SiC.tersoff Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff file. The final C argument maps LAMMPS atom type 4 to the C element in the Tersoff file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *tersoff* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Tersoff files in the *potentials* directory of the LAMMPS distribution have a “.tersoff” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- m
The n, β, λ₂, B, λ₁, and A parameters are only used for two-body interactions. The m, γ, λ₃, c, d, and \( \cos \theta_0 \) parameters are only used for three-body interactions. The R and D parameters are used for both two-body and three-body interactions. The non-annotated parameters are unitless. The value of m must be 3 or 1.

The Tersoff potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g., SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCsSi, CsSiCi, CsSiC, CsCsC, CsCsSi, CCC), that specify Tersoff parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiCC means Si bonded to a C with another C atom influencing the bond. Thus three-body parameters for SiCsSi and SiCiSi entries will not, in general, be the same. The parameters used for the two-body interaction come from the entry where the second element is repeated. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry.

The parameters used for a particular three-body interaction come from the entry with the corresponding three elements. The parameters used only for two-body interactions (n, β, λ₂, B, λ₁, and A) in entries whose second and third element are different (e.g. SiCsSi) are not used for anything and can be set to 0.0 if desired.

Note that the twobody parameters in entries such as SiCC and CsSi are often the same, due to the common use of symmetric mixing rules, but this is not always the case. For example, the beta and n parameters in Tersoff_2 (Tersoff_2) are not symmetric.

We chose the above form so as to enable users to define all commonly used variants of the Tersoff potential. In particular, our form reduces to the original Tersoff form when m = 3 and gamma = 1, while it reduces to the form of Albe et al. when beta = 1 and m = 1. Note that in the current Tersoff implementation in LAMMPS, m must be specified as either 3 or 1. Tersoff used a slightly different but equivalent form for alloys, which we will refer to as Tersoff_2 potential (Tersoff_2). The tersoff/table style implements Tersoff_2 parameterization only.

LAMMPS parameter values for Tersoff_2 can be obtained as follows: \( \gamma_{ijk} = \omega_{ik}, \lambda_3 = 0 \) and the value of m has no
effect. The parameters for species i and j can be calculated using the Tersoff_2 mixing rules:

\[
\begin{align*}
\lambda_{1}^{i,j} &= \frac{1}{2}(\lambda_{1}^{i} + \lambda_{1}^{j}) \\
\lambda_{2}^{i,j} &= \frac{1}{2}(\lambda_{2}^{i} + \lambda_{2}^{j}) \\
A_{i,j} &= (A_{i}A_{j})^{1/2} \\
B_{i,j} &= \chi_{ij}(B_{i}B_{j})^{1/2} \\
R_{i,j} &= (R_{i}R_{j})^{1/2} \\
S_{i,j} &= (S_{i}S_{j})^{1/2}
\end{align*}
\]

Tersoff_2 parameters R and S must be converted to the LAMMPS parameters R and D (R is different in both forms), using the following relations: \( R = (R^\prime + S^\prime)/2 \) and \( D = (S^\prime - R^\prime)/2 \), where the primes indicate the Tersoff_2 parameters.

In the potentials directory, the file SiCGe.tersoff provides the LAMMPS parameters for Tersoff’s various versions of Si, as well as his alloy parameters for Si, C, and Ge. This file can be used for pure Si, (three different versions), pure C, pure Ge, binary SiC, and binary SiGe. LAMMPS will generate an error if this file is used with any combination involving C and Ge, since there are no entries for the GeC interactions (Tersoff did not publish parameters for this cross-interaction.) Tersoff files are also provided for the SiC alloy (SiC.tersoff) and the GaN (GaN.tersoff) alloys.

Many thanks to Rutuparna Narulkar, David Farrell, and Xiaowang Zhou for helping clarify how Tersoff parameters for alloys have been defined in various papers.

---

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix} command-line switch when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

---

### 20.222.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \(!=\) J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the \textit{pair_modify} shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the \textit{pair} keyword of the \textit{run_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.
20.222.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The Tersoff potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the Tersoff potential with any LAMMPS units, but you would need to create your own Tersoff potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

pair_style tersoff/mod
pair_coeff * * Si.tersoff.mod Si Si
pair_style tersoff/mod/c
pair_coeff * * Si.tersoff.modc Si Si
```

20.224.3 Description

The `tersoff/mod` and `tersoff/mod/c` styles computes a bond-order type interatomic potential \( \text{Kumagai} \) based on a 3-body Tersoff potential \( \text{(Tersoff_1)}, \text{(Tersoff_2)} \) with modified cutoff function and angular-dependent term, giving the energy \( E \) of a system of atoms as

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}
\]

\[
V_{ij} = f_C(r_{ij}) \left[ f_R(r_{ij}) + b_{ij} f_A(r_{ij}) \right]
\]

\[
f_C(r) = \begin{cases} 
  \frac{1}{2} - \frac{9}{16} \sin \left( \frac{\pi}{2} \frac{r-R}{D} \right) - \frac{1}{16} \sin \left( \frac{3\pi}{2} \frac{r-R}{D} \right) & : \ r < R - D \\
  0 & : \ R - D < r < R + D \\
  1 & : \ r > R + D 
\end{cases}
\]

\[
f_R(r) = A \exp(-\lambda_1 r)
\]

\[
f_A(r) = -B \exp(-\lambda_2 r)
\]

\[
b_{ij} = (1 + \zeta_{ij}^n)^{-\frac{1}{n}}
\]

\[
\zeta_{ij} = \sum_{k \neq i,j} f_C(r_{ik}) g(\theta_{ijk}) \exp \left[ \alpha(r_{ij} - r_{ik})^2 \right]
\]

\[
g(\theta) = c_1 + g_o(\theta) g_a(\theta)
\]

\[
g_o(\theta) = \frac{c_2(h - \cos \theta)^2}{c_3 + (h - \cos \theta)^2}
\]

\[
g_a(\theta) = 1 + c_4 \exp \left[ -c_5(h - \cos \theta)^2 \right]
\]

where \( f_R \) is a two-body term and \( f_A \) includes three-body interactions. The summations in the formulae are over all neighbors \( J \) and \( K \) of atom \( I \) within a cutoff distance \( = R + D \). The `tersoff/mod/c` style differs from `tersoff/mod` only in the formulation of the \( V_{ij} \) term, where it contains an additional \( c_0 \) term.

\[
V_{ij} = f_C(r_{ij}) \left[ f_R(r_{ij}) + b_{ij} f_A(r_{ij}) + c_0 \right]
\]

The modified cutoff function \( f_C \) proposed by \( \text{(Murty)} \) and having a continuous second-order differential is employed. The angular-dependent term \( g(\theta) \) was modified to increase the flexibility of the potential.

The `tersoff/mod` potential is fitted to both the elastic constants and melting point by employing the modified Tersoff potential function form in which the angular-dependent term is improved. The model performs extremely well in describing the crystalline, liquid, and amorphous phases \( \text{(Schelling)} \).

Only a single `pair_coeff` command is used with the `tersoff/mod` style which specifies a Tersoff/MOD potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the `pair_coeff` command, where \( N \) is the number of LAMMPS atom types:

- filename
- \( N \) element names = mapping of Tersoff/MOD elements to atom types

As an example, imagine the `Si.tersoff_mod` file has Tersoff values for Si. If your LAMMPS simulation has 3 Si atoms types, you would use the following `pair_coeff` command:

20.224. `pair_style tersoff/mod/c command` 2019
pair_coeff * * Si.tersoff_mod Si Si Si

The first 2 arguments must be ** so as to span all LAMMPS atom types. The three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff/MOD file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a tersoff/mod potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Tersoff/MOD file in the potentials directory of the LAMMPS distribution have a “.tersoff.mod” suffix. Potential files for the tersoff/mod/c style have the suffix “.tersoff.modc”. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formulae above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- \( \beta \)
- \( \alpha \)
- h
- \( \eta \)
- \( \beta_{ters} = 1 \) (dummy parameter)
- \( \lambda_2 \) (1/distance units)
- B (energy units)
- R (distance units)
- D (distance units)
- \( \lambda_1 \) (1/distance units)
- A (energy units)
- n
- c1
- c2
- c3
- c4
- c5
- c0 (energy units, tersoff/mod/c only):ul

The n, \( \eta \), \( \lambda_2 \), \( \lambda_1 \), and A parameters are only used for two-body interactions. The \( \beta \), \( \alpha \), c1, c2, c3, c4, c5, h parameters are only used for three-body interactions. The R and D parameters are used for both two-body and three-body interactions. The c0 term applies to tersoff/mod/c only. The non-annotated parameters are unitless.

The Tersoff/MOD potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiSiSi means Si bonded to a Si with another Si atom influencing the bond.
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

---

### 20.224.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

---

### 20.224.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

The Tersoff/MOD potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the Tersoff/MOD potential with any LAMMPS units, but you would need to create your own Tersoff/MOD potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

20.225 pair_style tersoff/zbl command

Accelerator Variants: tersoff/zbl/gpu, tersoff/zbl/kk, tersoff/zbl/omp

20.225.1 Syntax

pair_style tersoff/zbl

20.225.2 Examples

pair_style tersoff/zbl
pair_coeff * * SiC.tersoff.zbl Si C Si

20.225.3 Description

The tersoff/zbl style computes a 3-body Tersoff potential (Tersoff_1) with a close-separation pairwise modification based on a Coulomb potential and the Ziegler-Biersack-Littmark universal screening function (ZBL), giving the energy $E$ of a system of atoms as

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = (1 - f_F(r_{ij})) V_{ij}^{ZBL} + f_F(r_{ij}) V_{ij}^{Tersoff}$$

$$f_F(r_{ij}) = \frac{1}{1 + e^{-A_F(r_{ij} - r_C)}}$$

$$V_{ij}^{ZBL} = \frac{Z_1 Z_2 e^2}{4\pi \epsilon_0} \phi(r_{ij}/a)$$

$$a = \frac{0.8854 a_0}{Z_1^{0.21} + Z_2^{0.23}}$$

$$\phi(x) = 0.1818e^{-3.2x} + 0.5099e^{-0.9423x} + 0.2802e^{-0.4029x} + 0.02817e^{-0.2016x}$$

$$V_{ij}^{Tersoff} = f_C(r_{ij}) \left[ f_R(r_{ij}) + b_{ij} f_A(r_{ij}) \right]$$

$$f_C(r) = \begin{cases} 1 : & r < R - D \\ \frac{1}{2} - \frac{1}{2} \sin \left( \frac{r - R}{2D} \right) : & R - D < r < R + D \\ 0 : & r > R + D \end{cases}$$

$$f_R(r) = A \exp(-\lambda_1 r)$$

$$f_A(r) = -B \exp(-\lambda_2 r)$$

$$b_{ij} = (1 + \beta^n \zeta_{ij})^{-\frac{1}{4\pi}}$$

$$\zeta_{ij} = \sum_{k \neq i,j} f_C(r_{ik}) g(\theta_{ijk}) \exp \left[ \lambda_3^m (r_{ij} - r_{ik})^m \right]$$

$$g(\theta) = \gamma_{ijk} \left( 1 + \frac{c^2}{d^2} - \frac{c^2}{[d^2 + (\cos \theta - \cos \theta_0)^2]} \right)$$
The $f_F$ term is a fermi-like function used to smoothly connect the ZBL repulsive potential with the Tersoff potential. There are 2 parameters used to adjust it: $A_F$ and $r_C$. $A_F$ controls how “sharp” the transition is between the two, and $r_C$ is essentially the cutoff for the ZBL potential.

For the ZBL portion, there are two terms. The first is the Coulomb repulsive term, with $Z_1, Z_2$ as the number of protons in each nucleus, $e$ as the electron charge (1 for metal and real units) and $\epsilon_0$ as the permittivity of vacuum. The second part is the ZBL universal screening function, with $a_0$ being the Bohr radius (typically 0.529 Angstroms), and the remainder of the coefficients provided by the original paper. This screening function should be applicable to most systems. However, it is only accurate for small separations (i.e. less than 1 Angstrom).

For the Tersoff portion, $f_R$ is a two-body term and $f_A$ includes three-body interactions. The summations in the formula are over all neighbors J and K of atom I within a cutoff distance = $R + D$.

Only a single pair_coeff command is used with the tersoff/zbl style which specifies a Tersoff/ZBL potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of Tersoff/ZBL elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, imagine the SiC.tersoff.zbl file has Tersoff/ZBL values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * SiC.tersoff Si Si Si C
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff/ZBL file. The final C argument maps LAMMPS atom type 4 to the C element in the Tersoff/ZBL file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a tersoff/zbl potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Tersoff/ZBL files in the potentials directory of the LAMMPS distribution have a “.tersoff.zbl” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- $m$
- $\gamma$
- $\lambda_3$ (1/distance units)
- $c$
- $d$
- $\cos \theta_0$ (can be a value < -1 or > 1)
- $n$
- $\beta$
- $\lambda_2$ (1/distance units)
- $B$ (energy units)
LAMMPS Documentation

- \( R \) (distance units)
- \( D \) (distance units)
- \( \lambda_1 \) (1/distance units)
- \( A \) (energy units)
- \( Z_i \)
- \( Z_j \)
- \( ZBLcut \) (distance units)
- \( ZBLexpscale \) (1/distance units)

The \( n, \beta, \lambda_2, B, \lambda_1, \) and \( A \) parameters are only used for two-body interactions. The \( m, \gamma, \lambda_3, c, d, \) and \( \cos \theta_0 \) parameters are only used for three-body interactions. The \( R \) and \( D \) parameters are used for both two-body and three-body interactions. The \( Z_i, Z_j, ZBLcut, ZBLexpscale \) parameters are used in the ZBL repulsive portion of the potential and in the Fermi-like function. The non-annotated parameters are unitless. The value of \( m \) must be 3 or 1.

The Tersoff/ZBL potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCsi, SiCC, CsiSi, CsiC, CCSi, CCC), that specify Tersoff parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiCC means Si bonded to a C with another C atom influencing the bond. Thus three-body parameters for SiCsi and SiSiC entries will not, in general, be the same. The parameters used for the two-body interaction come from the entry where the second element is repeated. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry.

The parameters used for a particular three-body interaction come from the entry with the corresponding three elements. The parameters used only for two-body interactions (\( n, \beta, \lambda_2, B, \lambda_1, \) and \( A \)) in entries whose second and third element are different (e.g. SiCsi) are not used for anything and can be set to 0.0 if desired.

Note that the two-body parameters in entries such as SiCC and CsiSi are often the same, due to the common use of symmetric mixing rules, but this is not always the case. For example, the beta and n parameters in Tersoff_2 (Tersoff_2) are not symmetric.

We chose the above form so as to enable users to define all commonly used variants of the Tersoff portion of the potential. In particular, our form reduces to the original Tersoff form when \( m = 3 \) and \( \gamma = 1 \), while it reduces to the form of Albe et al. when \( \beta = 1 \) and \( m = 1 \). Note that in the current Tersoff implementation in LAMMPS, \( m \) must be specified as either 3 or 1. Tersoff used a slightly different but equivalent form for alloys, which we will refer to as Tersoff_2 potential (Tersoff_2).

LAMMPS parameter values for Tersoff_2 can be obtained as follows: \( \gamma = \omega_{ij}, \lambda_3 = 0 \) and the value of \( m \) has no effect. The parameters for species i and j can be calculated using the Tersoff_2 mixing rules:

\[
\lambda_{1}^{i,j} = \frac{1}{2}(\lambda_{1}^{i} + \lambda_{1}^{j}) \\
\lambda_{2}^{i,j} = \frac{1}{2}(\lambda_{2}^{i} + \lambda_{2}^{j}) \\
A_{i,j} = (A_{i}A_{j})^{1/2} \\
B_{i,j} = \chi_{ij}(B_{i}B_{j})^{1/2} \\
R_{i,j} = (R_{i}R_{j})^{1/2} \\
S_{i,j} = (S_{i}S_{j})^{1/2}
\]
Tersoff\_2 parameters R and S must be converted to the LAMMPS parameters R and D (R is different in both forms), using the following relations: \( R=(R'+S')/2 \) and \( D=(S'-R')/2 \), where the primes indicate the Tersoff\_2 parameters.

In the potentials directory, the file SiCGe.tersoff provides the LAMMPS parameters for Tersoff's various versions of Si, as well as his alloy parameters for Si, C, and Ge. This file can be used for pure Si, (three different versions), pure C, pure Ge, binary SiC, and binary SiGe. LAMMPS will generate an error if this file is used with any combination involving C and Ge, since there are no entries for the GeC interactions (Tersoff did not publish parameters for this cross-interaction.) Tersoff files are also provided for the SiC alloy (SiC.tersoff) and the GaN (GaN.tersoff) alloys.

Many thanks to Rutuparna Narulkar, David Farrell, and Xiaowang Zhou for helping clarify how Tersoff parameters for alloys have been defined in various papers. Also thanks to Ram Devanathan for providing the base ZBL implementation.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

\section*{20.225.4 Mixing, shift, table, tail correction, restart, rRESPA info}

For atom type pairs I, J and I \(!= J\), where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the \texttt{pair_modify} shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair\_style and pair\_coeff commands in an input script that reads a restart file.

This pair style can only be used via the \texttt{pair} keyword of the \texttt{run_style respa} command. It does not support the \texttt{inner}, \texttt{middle}, \texttt{outer} keywords.

\section*{20.225.5 Restrictions}

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

This pair style requires the \texttt{newton} setting to be “on” for pair interactions.

The Tersoff/ZBL potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the Tersoff potential with any LAMMPS units, but you would need to create your own Tersoff potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

20.226 pair_style thole command

20.227 pair_style lj/cut/thole/long command

Accelerator Variants: lj/cut/thole/long/omp

20.227.1 Syntax

```
pair_style style args
```

- style = thole or lj/cut/thole/long or lj/cut/thole/long/omp
- args = list of arguments for a particular style

**thole args** = damp cutoff
  - damp = global damping parameter
  - cutoff = global cutoff (distance units)

**lj/cut/thole/long or lj/cut/thole/long/omp args** = damp cutoff (cutoff2)
  - damp = global damping parameter
  - cutoff = global cutoff for LJ (and Thole if only 1 arg) (distance units)
  - cutoff2 = global cutoff for Thole (optional) (distance units)

20.227.2 Examples

```
pair_style hybrid/overlay ... thole 2.6 12.0
pair_coeff 1 1 thole 1.0
pair_coeff 1 2 thole 1.0 2.6 10.0
pair_coeff * 2 thole 1.0 2.6
pair_style lj/cut/thole/long 2.6 12.0
```
20.227.3 Description

The *thole* pair styles are meant to be used with force fields that include explicit polarization through Drude dipoles. This link describes how to use the *thermalized Drude oscillator model* in LAMMPS and polarizable models in LAMMPS are discussed on the *Howto polarizable* doc page.

The *thole* pair style should be used as a sub-style within in the *pair_style hybrid/overlay* command, in conjunction with a main pair style including Coulomb interactions, i.e. any pair style containing *coul/cut* or *coul/long* in its style name.

The *lj/cut/thole/long* pair style is equivalent to, but more convenient that the frequent combination *hybrid/overlay* *lj/cut/coul/long* cutoff thole damp cutoff2. It is not only a shorthand for this pair_style combination, but it also allows for mixing pair coefficients instead of listing them all. The *lj/cut/thole/long* pair style is also a bit faster because it avoids an overlay and can benefit from OMP acceleration. Moreover, it uses a more precise approximation of the direct Coulomb interaction at short range similar to *coul/long/cs*, which stabilizes the temperature of Drude particles.

The *thole* pair styles compute the Coulomb interaction damped at short distances by a function

\[ T_{ij}(r_{ij}) = 1 - \left(1 + \frac{s_{ij}r_{ij}}{2}\right) \exp\left(-s_{ij}r_{ij}\right) \]

This function results from an adaptation to point charges (Noskov) of the dipole screening scheme originally proposed by Thole. The scaling coefficient \( s_{ij} \) is determined by the polarizability of the atoms, \( \alpha_i \), and by a Thole damping parameter \( a \). This Thole damping parameter usually takes a value of 2.6, but in certain force fields the value can depend upon the atom types. The mixing rule for Thole damping parameters is the arithmetic average, and for polarizabilities the geometric average between the atom-specific values.

\[ s_{ij} = \frac{a_{ij}}{(\alpha_{ij})^{1/3}} = \frac{(a_i + a_j)/2}{[(\alpha_i\alpha_j)^{1/2}]^{1/3}} \]

The damping function is only applied to the interactions between the point charges representing the induced dipoles on polarizable sites, that is, charges on Drude particles, \( q_{D,i} \), and opposite charges, \(-q_{D,i}\), located on the respective core particles (to which each Drude particle is bonded). Therefore, Thole screening is not applied to the full charge of the core particle \( q_i \), but only to the \(-q_{D,i}\) part of it.

The interactions between core charges are subject to the weighting factors set by the *special_bonds* command. The interactions between Drude particles and core charges or non-polarizable atoms are also subject to these weighting factors. The Drude particles inherit the 1-2, 1-3 and 1-4 neighbor relations from their respective cores.

For pair_style *thole*, the following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the example above.

- \( \alpha \) (distance units^3)
- damp
- cutoff (distance units)

The last two coefficients are optional. If not specified the global Thole damping parameter or global cutoff specified in the pair_style command are used. In order to specify a cutoff (third argument) a damp parameter (second argument) must also be specified.

For pair style *lj/cut/thole/long*, the following coefficients must be defined for each pair of atoms types via the *pair_coeff* command.

- \( \epsilon \) (energy units)
- \( \sigma \) (length units)
- \( \alpha \) (distance units^3)
- damp
LAMMPS Documentation

- LJ cutoff (distance units)

The last two coefficients are optional and default to the global values from the pair_style command line.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.227.4 Mixing, shift, table, tail correction, restart, rRESPA info

The thole pair style does not support mixing. Thus, coefficients for all LJ pairs must be specified explicitly.

The lj/cut/thole/long pair style does support mixing. Mixed coefficients are defined using

\[ \alpha_{ij} = \sqrt{\alpha_i \alpha_j} \]

\[ a_{ij} = \frac{1}{2}(a_i + a_j) \]

20.227.5 Restrictions

These pair styles are part of the USER-DRUDE package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair_style should currently not be used with the charmm dihedral style if the latter has non-zero 1-4 weighting factors. This is because the thole pair style does not know which pairs are 1-4 partners of which dihedrals.

The lj/cut/thole/long pair style should be used with a Kspace solver like PPPM or Ewald, which is only enabled if LAMMPS was built with the kspace package.

20.228 pair_style tri/lj command

20.228.1 Syntax

pair_style tri/lj cutoff

Cutoff = global cutoff for interactions (distance units)

20.228.2 Examples

pair_style tri/lj 3.0
pair_coeff * * 1.0 1.0
pair_coeff 1 1 1.0 1.5 2.5

20.228.3 Description

Style tri/lj treats particles which are triangles as a set of small spherical particles that tile the triangle surface as explained below. Interactions between two triangles, each with N1 and N2 spherical particles, are calculated as the pairwise sum of N1*N2 Lennard-Jones interactions. Interactions between a triangle with N spherical particles and a point particle are treated as the pairwise sum of N Lennard-Jones interactions. See the pair_style lj/cut doc page for the definition of Lennard-Jones interactions.

The cutoff distance for an interaction between 2 triangles, or between a triangle and a point particle, is calculated from the position of the triangle (its centroid), not between pairs of individual spheres comprising the triangle. Thus an interaction is either calculated in its entirety or not at all.

The set of non-overlapping spherical particles that represent a triangle, for purposes of this pair style, are generated in the following manner. Assume the triangle is of type I, and sigma_II has been specified. We want a set of spheres with centers in the plane of the triangle, none of them larger in diameter than sigma_II, which completely cover the triangle’s area, but with minimal overlap and a minimal total number of spheres. This is done in a recursive manner. Place a sphere at the centroid of the original triangle. Calculate what diameter it must have to just cover all 3 corner points of the triangle. If that diameter is equal to or smaller than sigma_II, then include a sphere of the calculated diameter in the set of covering spheres. If the diameter is larger than sigma_II, then split the triangle into 2 triangles by bisecting its longest side. Repeat the process on each sub-triangle, recursing as far as needed to generate a set of covering spheres. When finished, the original criteria are met, and the set of covering spheres should be near minimal in number and overlap, at least for input triangles with a reasonable aspect-ratio.

The LJ interaction between 2 spheres on different triangles of types IJ is computed with an arithmetic mixing of the sigma values of the 2 spheres and using the specified epsilon value for IJ atom types. Note that because the sigma values for triangles spheres is computed using only sigma_II values, which completely cover the triangle’s area, any specified sigma_IJ values (for I != J) are effectively ignored.

For style tri/lj, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- epsilon (energy units)
- sigma (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.
20.228.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of this pair style can be
mixed. The default mix value is geometric. See the “pair_modify” command for details.
This pair style does not support the pair_modify shift, table, and tail options.
This pair style does not write its information to binary restart files.
This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.228.5 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.
Defining particles to be triangles so they participate in tri/tri or tri/particle interactions requires the use the atom_style tri command.

20.228.6 Related commands

pair_coeff, pair_style line/lj

20.228.7 Default

none

20.229 pair_style ufm command

Accelerator Variants: ufm/gpu, ufm/omp, ufm/opt

20.229.1 Syntax

pair_style ufm cutoff

- cutoff = global cutoff for ufm interactions (distance units)

20.229.2 Examples

pair_style ufm 4.0
pair_coeff 1 1 100.0 1.0 2.5
pair_coeff * * 100.0 1.0

pair_style ufm 4.0
pair_coeff * * 10.0 1.0
variable prefactor equal ramp(10,100)
fix 1 all adapt 1 pair ufm epsilon * * v_prefactor
20.229.3 Description

Style ufm computes pairwise interactions using the Uhlenbeck-Ford model (UFM) potential (Paula Leite2016) which is given by

\[ E = -\varepsilon \ln \left[ 1 - \exp \left( -\frac{r^2}{\sigma^2} \right) \right] \quad r < r_c \]

\[ \varepsilon = p k_B T \]

where \( r_c \) is the cutoff, \( \sigma \) is a distance-scale and \( \varepsilon \) is an energy-scale, i.e., a product of Boltzmann constant \( k_B \), temperature \( T \) and the Uhlenbeck-Ford \( p \)-parameter which is responsible to control the softness of the interactions (Paula Leite2017). This model is useful as a reference system for fluid-phase free-energy calculations (Paula Leite2016).

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- \( \varepsilon \) (energy units)
- \( \sigma \) (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global ufm cutoff is used.

The fix adapt command can be used to vary epsilon and sigma for this pair style over the course of a simulation, in which case pair_coeff settings for epsilon and sigma must still be specified, but will be overridden. For example these commands will vary the prefactor epsilon for all pairwise interactions from 10.0 at the beginning to 100.0 at the end of a run:

```plaintext
variable prefactor equal ramp(10,100)
fix 1 all adapt 1 pair ufm epsilon * * v_preactor
```

Note: The thermodynamic integration procedure can be performed with this potential using fix adapt. This command will rescale the force on each atom by varying a scale variable, which always starts with value 1.0. The syntax is the same described above, however, changing epsilon to scale. A detailed explanation of how to use this command and perform nonequilibrium thermodynamic integration in LAMMPS is given in the paper by (Freitas).

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
20.229.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table and tail are not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

pair_style vashishta/table 100000 0.2
pair_coeff * * SiC.vashishta Si C
```

20.231.3 Description

The `vashishta` and `vashishta/table` styles compute the combined 2-body and 3-body family of potentials developed in the group of Priya Vashishta and collaborators. By combining repulsive, screened Coulombic, screened charge-dipole, and dispersion interactions with a bond-angle energy based on the Stillinger-Weber potential, this potential has been used to describe a variety of inorganic compounds, including SiO$_2$ [Vashishta1990], SiC [Vashishta2007], and InP [Branicio2009].

The potential for the energy $U$ of a system of atoms is

$$U = \sum_i^n \sum_j^n U_{ij}^{(2)}(r_{ij}) + \sum_i^n \sum_{j \neq i}^n \sum_{k \neq j} U_{ijk}^{(3)}(r_{ij}, r_{ik}, \theta_{ijk})$$

$$U_{ij}^{(2)}(r) = \frac{H_{ij}}{r^{\eta_{ij}}} + \frac{Z_i Z_j}{r} \exp(-r/\lambda_{1,ij}) - \frac{D_{ij}}{r^4} \exp(-r/\lambda_{4,ij}) - \frac{W_{ij}}{r^6}, r < r_{c,ij}$$

$$U_{ijk}^{(3)}(r_{ij}, r_{ik}, \theta_{ijk}) = B_{ijk} \frac{[\cos \theta_{ijk} - \cos \theta_{0,ijk}]^2}{1 + C_{ijk} [\cos \theta_{ijk} - \cos \theta_{0,ijk}]^2} \times \exp \left( \frac{\gamma_{ij}}{r_{ij} - r_{0,ij}} \right) \exp \left( \frac{\gamma_{ik}}{r_{ik} - r_{0,ik}} \right), r_{ij} < r_{0,ij}, r_{ik} < r_{0,ik}$$

where we follow the notation used in [Branicio2009]. $U^2$ is a two-body term and $U^3$ is a three-body term. The summation over two-body terms is over all neighbors $J$ within a cutoff distance $= r_c$. The twobody terms are shifted and tilted by a linear function so that the energy and force are both zero at $r_c$. The summation over three-body terms is over all neighbors $i$ and $k$ within a cut-off distance $= r_0$, where the exponential screening function becomes zero.

The `vashishta` style computes these formulas analytically. The `vashishta/table` style tabulates the analytic values for $Ntable$ points from cutinner to the cutoff of the potential. The points are equally spaced in $R^2$ space from cutinner$^2$ to cutoff$^2$. For the two-body term in the above equation, a linear interpolation for each pairwise distance between adjacent points in the table. In practice the tabulated version can run 3-5x faster than the analytic version with moderate to little loss of accuracy for Ntable values between 10000 and 1000000. It is not recommended to use less than 5000 tabulation points.
Only a single pair_coeff command is used with either style which specifies a Vashishta potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of Vashishta elements to atom types

See the pair_coeff doc page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.vashishta has parameters for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```lmp
pair_coeff * * SiC.vashishta Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the file. The final C argument maps LAMMPS atom type 4 to the C element in the file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a vashishta potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Vashishta files in the potentials directory of the LAMMPS distribution have a “.vashishta” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formulae above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- \( H \) (energy units)
- \( \eta \)
- \( Z_i \) (electron charge units)
- \( Z_j \) (electron charge units)
- \( \lambda_1 \) (distance units)
- \( D \) (energy units)
- \( \lambda_4 \) (distance units)
- \( W \) (energy units)
- \( r_c \) (distance units)
- \( B \) (energy units)
- \( \gamma \)
- \( r_0 \) (distance units)
- \( C \)
- \( \cos \theta_0 \)

The non-annotated parameters are unitless. The Vashishta potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries. For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.
Depending on the particular version of the Vashishta potential, the values of these parameters may be keyed to the identities of zero, one, two, or three elements. In order to make the input file format unambiguous, general, and simple to code, LAMMPS uses a slightly confusing method for specifying parameters. All parameters are divided into two classes: two-body and three-body. Two-body and three-body parameters are handled differently, as described below. The two-body parameters are $H$, $\eta$, $\lambda_1$, $D$, $\lambda_4$, $W$, $r_c$, $\gamma$, and $r_0$. They appear in the above formulae with two subscripts. The parameters $Z_i$ and $Z_j$ are also classified as two-body parameters, even though they only have 1 subscript. The three-body parameters are $B$, $C$, $\cos \theta_0$. They appear in the above formulae with three subscripts. Two-body and three-body parameters are handled differently, as described below.

The first element in each entry is the center atom in a three-body interaction, while the second and third elements are two neighbor atoms. Three-body parameters for a central atom I and two neighbors J and K are taken from the IJK entry. Note that even though three-body parameters do not depend on the order of J and K, LAMMPS stores three-body parameters for both IJK and IKJ. The user must ensure that these values are equal. Two-body parameters for an atom I interacting with atom J are taken from the IJ entry, where the second and third elements are the same. Thus the two-body parameters for Si interacting with C come from the SiCC entry. Note that even though two-body parameters (except possibly gamma and r0 in U3) do not depend on the order of the two elements, LAMMPS will get the Si-C value from the SiCC entry and the C-Si value from the CSI Si entry. The user must ensure that these values are equal. Two-body parameters appearing in entries where the second and third elements are different are stored but never used. It is good practice to enter zero for these values. Note that the three-body function U3 above contains the two-body parameters $\gamma$ and $r_0$. So U3 for a central C atom bonded to an Si atom and a second C atom will take three-body parameters from the CSiC entry, but two-body parameters from the CCC and CSI Si entries.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.231.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.
20.231.5 Restrictions

These pair style are part of the MANYBODY package. They is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

These pair styles requires the newton setting to be “on” for pair interactions.

The Vashishta potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the Vashishta potential with any LAMMPS units, but you would need to create your own potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

pair_style yukawa kappa cutoff

- kappa = screening length (inverse distance units)
- cutoff = global cutoff for Yukawa interactions (distance units)

20.232.2 Examples

pair_style yukawa 2.0 2.5
pair_coeff 1 1 100.0 2.3
pair_coeff * * 100.0
20.232.3 Description

Style yukawa computes pairwise interactions with the formula

\[ E = A \frac{e^{-kr}}{r} \quad r < r_c \]

\( r_c \) is the cutoff.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- A (energy*distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global yukawa cutoff is used.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

20.232.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I ≠ J, the A coefficient and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.
20.232.5 Restrictions

none

20.232.6 Related commands

pair_coeff

20.232.7 Default

none

20.233 pair_style yukawa/colloid command

Accelerator Variants: yukawa/colloid/gpu, yukawa/colloid/omp

20.233.1 Syntax

```
pair_style yukawa/colloid kappa cutoff
```

- kappa = screening length (inverse distance units)
- cutoff = global cutoff for colloidal Yukawa interactions (distance units)

20.233.2 Examples

```
pair_style yukawa/colloid 2.0 2.5
pair_coeff 1 1 100.0 2.3
pair_coeff * * 100.0
```

20.233.3 Description

Style yukawa/colloid computes pairwise interactions with the formula

\[ E = \frac{A}{\kappa} e^{-\kappa (r - (r_i + r_j))} \quad r < r_c \]

where \( r_i \) and \( r_j \) are the radii of the two particles and \( r_c \) is the cutoff.

In contrast to pair_style yukawa, this functional form arises from the Coulombic interaction between two colloid particles, screened due to the presence of an electrolyte, see the book by Safran for a derivation in the context of DLVO theory. Pair_style yukawa is a screened Coulombic potential between two point-charges and uses no such approximation.

This potential applies to nearby particle pairs for which the Derjagin approximation holds, meaning \( h << r_i + r_j \), where \( h \) is the surface-to-surface separation of the two particles.

When used in combination with pair_style colloid, the two terms become the so-called DLVO potential, which combines electrostatic repulsion and van der Waals attraction.
The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- A (energy/distance units)
- cutoff (distance units)

The prefactor A is determined from the relationship between surface charge and surface potential due to the presence of electrolyte. Note that the A for this potential style has different units than the A used in `pair_style yukawa`. For low surface potentials, i.e. less than about 25 mV, A can be written as:

\[ A = 2\pi R\varepsilon_0\kappa\psi^2 \]

where

- \( R \) = colloid radius (distance units)
- \( \varepsilon_0 \) = permittivity of free space (charge^2/energy/distance units)
- \( \varepsilon \) = relative permittivity of fluid medium (dimensionless)
- \( \kappa \) = inverse screening length (1/distance units)
- \( \psi \) = surface potential (energy/charge units)

The last coefficient is optional. If not specified, the global yukawa/colloid cutoff is used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 20.233.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I \(!=\) J, the A coefficient and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the `pair_modify` shift option for the energy of the pair interaction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.
20.233.5 Restrictions

This style is part of the COLLOID package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This pair style requires that atoms be finite-size spheres with a diameter, as defined by the atom_style sphere command. Per-particle polydispersity is not yet supported by this pair style; per-type polydispersity is allowed. This means all particles of the same type must have the same diameter. Each type can have a different diameter.

20.233.6 Related commands

pair_coeff

20.233.7 Default

none

20.234 pair_style zbl command

Accelerator Variants: zbl/gpu, zbl/kk, zbl/omp

20.234.1 Syntax

```
pair_style zbl inner outer
```

- `inner` = distance where switching function begins
- `outer` = global cutoff for ZBL interaction

20.234.2 Examples

```
pair_style zbl 3.0 4.0
pair_coeff * * 73.0 73.0
pair_coeff 1 1 14.0 14.0
```

20.234.3 Description

Style `zbl` computes the Ziegler-Biersack-Littmark (ZBL) screened nuclear repulsion for describing high-energy collisions between atoms. (Ziegler). It includes an additional switching function that ramps the energy, force, and curvature
smoothly to zero between an inner and outer cutoff. The potential energy due to a pair of atoms at a distance \( r_{ij} \) is given by:

\[
E_{ij}^{ZBL} = \frac{Z_i Z_j e^2}{4\pi\epsilon_0 r_{ij}} \phi(\frac{r_{ij}}{a}) + S(r_{ij})
\]

\[
a = \frac{0.46850}{Z_i^{0.23} + Z_j^{0.23}}
\]

\[
\phi(x) = 0.18175 e^{-3.19980x} + 0.50986 e^{-0.94229x} + 0.28022 e^{-0.40290x} + 0.02817 e^{-0.20162x}
\]

where \( e \) is the electron charge, \( \epsilon_0 \) is the electrical permittivity of vacuum, and \( Z_i \) and \( Z_j \) are the nuclear charges of the two atoms. The switching function \( S(r) \) is identical to that used by pair style lj/gromacs. Here, the inner and outer cutoff are the same for all pairs of atom types.

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the LAMMPS data file.

- \( Z_i \) (atomic number for first atom type, e.g. 13.0 for aluminum)
- \( Z_j \) (ditto for second atom type)

The values of \( Z_i \) and \( Z_j \) are normally equal to the atomic numbers of the two atom types. Thus, the user may optionally specify only the coefficients for each \( i == i \) pair, and rely on the obvious mixing rule for cross interactions (see below). Note that when \( i == i \) it is required that \( Z_i == Z_j \). When used with hybrid/overlay and pairs are assigned to more than one sub-style, the mixing rule is not used and each pair of types interacting with the ZBL sub-style must be included in a pair_coeff command.

**Note:** The numerical values of the exponential decay constants in the screening function depend on the unit of distance. In the above equation they are given for units of angstroms. LAMMPS will automatically convert these values to the distance unit of the specified LAMMPS units setting. The values of \( Z \) should always be given as multiples of a proton’s charge, e.g. 29.0 for copper.

---

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
20.234.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs \( i, j \) and \( i \neq i \), the \( Z_i \) and \( Z_j \) coefficients can be mixed by taking \( Z_i \) and \( Z_j \) from the values specified for \( i == i \) and \( j == j \) cases. When used with hybrid/overlay and pairs are assigned to more than one sub-style, the mixing rule is not used and each pair of types interacting with the ZBL sub-style must be included in a pair_coeff command. The pair_modify mix option has no effect on the mixing behavior.

The ZBL pair style does not support the pair_modify shift option, since the ZBL interaction is already smoothed to 0.0 at the cutoff.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

This pair style does not write information to binary restart files, so pair_style and pair_coeff commands must be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

20.234.5 Restrictions

none

20.234.6 Related commands

pair_coeff

20.234.7 Default

20.235 pair_style zero command

20.235.1 Syntax

```plaintext
pair_style zero cutoff [nocoeff]
```

- `zero` = style name of this pair style
- `cutoff` = global cutoff (distance units)
- `nocoeff` = ignore all pair_coeff parameters (optional)
20.235.2 Examples

```
pair_style zero 10.0
pair_style zero 5.0 nocoeff
pair_coeff * *
pair_coeff 1 2 4 3.0
```

20.235.3 Description

Define a global or per-type cutoff length for the purpose of building a neighbor list and acquiring ghost atoms, but do not compute any pairwise forces or energies.

This can be useful for fixes or computes which require a neighbor list to enumerate pairs of atoms within some cutoff distance, but when pairwise forces are not otherwise needed. Examples are the fix bond/create, compute rdf, compute voronoi/atom commands.

Note that the comm_modify cutoff command can be used to insure communication of ghost atoms even when a pair style is not defined, but it will not trigger neighbor list generation.

The optional nocoeff flag allows to read data files with a PairCoeff section for any pair style. Similarly, any pair_coeff commands will only be checked for the atom type numbers and the rest ignored. In this case, only the global cutoff will be used.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- cutoff (distance units)

This coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used. If the pair_style has been specified with the optional nocoeff flag, then a cutoff pair coefficient is ignored.

20.235.4 Mixing, shift, table, tail correction, restart, rRESPA info

The cutoff distance for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the inner, middle, and outer keywords of the run_style respa command.

bond_coeff 1 30.0 1.5 1.0 1.0
```
21.2.3 Description

The *fene* bond style uses the potential

\[ E = -0.5KR_0^2 \ln \left( 1 - \left( \frac{r}{R_0} \right)^2 \right) + 4\epsilon \left( \left( \frac{\sigma}{r} \right)^6 - \left( \frac{\sigma}{r} \right)^{12} \right) + \epsilon \]

to define a finite extensible nonlinear elastic (FENE) potential (*Kremer*), used for bead-spring polymer models. The first term is attractive, the second Lennard-Jones term is repulsive. The first term extends to \( R_0 \), the maximum extent of the bond. The second term is cutoff at \( 2^{\frac{1}{6}}\sigma \), the minimum of the LJ potential.

The following coefficients must be defined for each bond type via the *bond_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( K \) (energy/distance^2)
- \( R_0 \) (distance)
- \( \epsilon \) (energy)
- \( \sigma \) (distance)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

21.2.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

You typically should specify *special_bonds fene* or *special_bonds lj/coul 0 1 1* to use this bond style. LAMMPS will issue a warning if that’s not the case.

21.2.5 Related commands

*bond_coeff*, *delete_bonds*

21.3 bond_style fene/expand command

Accelerator Variants: fene/expand/omp

21.3.1 Syntax

```
bond_style fene/expand
```

21.3.2 Examples

```
bond_style fene/expand
bond_coeff 1 30.0 1.5 1.0 1.0 0.5
```

21.3.3 Description

The fene/expand bond style uses the potential

\[ E = -0.5KR_0^2 \ln \left[ 1 - \left( \frac{r - \Delta}{R_0} \right)^2 \right] + 4\epsilon \left[ \left( \frac{\sigma}{r - \Delta} \right)^{12} - \left( \frac{\sigma}{r - \Delta} \right)^6 \right] + \epsilon \]

to define a finite extensible nonlinear elastic (FENE) potential (Kremer), used for bead-spring polymer models. The first term is attractive, the second Lennard-Jones term is repulsive.

The fene/expand bond style is similar to fene except that an extra shift factor of \( \Delta \) (positive or negative) is added to \( r \) to effectively change the bead size of the bonded atoms. The first term now extends to \( R_0 + \Delta \) and the second term is cutoff at \( 2^{1/6} \sigma + \Delta \).

The following coefficients must be defined for each bond type via the bond_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy/distance^2)
- \( R_0 \) (distance)
- \( \epsilon \) (energy)
- \( \sigma \) (distance)
- \( \Delta \) (distance)

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. ### 21.7.6 Default

`none`

### 21.8 bond_style hybrid command

#### 21.8.1 Syntax

```bash
bond_style hybrid style1 style2 ...
```

- `style1,style2 = list of one or more bond styles`

#### 21.8.2 Examples

#### 21.8.3 Description

The *hybrid* style enables the use of multiple bond styles in one simulation. A bond style is assigned to each bond type. For example, bonds in a polymer flow (of bond type 1) could be computed with a *fene* potential and bonds in the wall boundary (of bond type 2) could be computed with a *harmonic* potential. The assignment of bond type to style is made via the `bond_coeff` command or in the data file.

In the bond_coeff commands, the name of a bond style must be added after the bond type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 bond_coeff commands set bonds of bond...
type 1 to be computed with a harmonic potential with coefficients 80.0, 1.2 for $K, r_0$. All other bond types (2-N) are computed with a fene potential with coefficients 30.0, 1.5, 1.0, 1.0 for $K, R_0, \epsilon, \sigma$.

If bond coefficients are specified in the data file read via the read_data command, then the same rule applies. E.g. “harmonic” or “fene” must be added after the bond type, for each line in the “Bond Coeffs” section, e.g.

```
Bond Coeffs

  1 harmonic 80.0 1.2
  2 fene 30.0 1.5 1.0 1.0
...
```

A bond style of none with no additional coefficients can be used in place of a bond style, either in a input script bond_coeff command or in the data file, if you desire to turn off interactions for specific bond types.

## 21.8.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

Unlike other bond styles, the hybrid bond style does not store bond coefficient info for individual sub-styles in a binary restart files. Thus when restarting a simulation from a restart file, you need to re-specify bond_coeff commands.

## 21.8.5 Related commands

`bond_coeff`, `delete_bonds`

## 21.9 bond_style mm3 command

### 21.9.1 Syntax

```
bond_style mm3
```

### 21.9.2 Examples

```
bond_style mm3
bond_coeff 1 100.0 107.0
```
21.9.3 Description

The *mm3* bond style uses the potential that is anharmonic in the bond as defined in *(Allinger)*

\[ E = K (r - r_0)^2 \left[ 1 - 2.55(r - r_0) + \frac{7}{12}2.55^2(r - r_0)^2 \right] \]

where \( r_0 \) is the equilibrium value of the bond, and \( K \) is a prefactor. The anharmonic prefactors have units angstrom^(-n): -2.55 angstrom^(-1) and \((7/12)2.55^2\) angstrom^(-2). The code takes care of the necessary unit conversion for these factors internally. Note that the MM3 papers contains an error in Eq (1): \((7/12)2.55\) should be replaced with \((7/12)2.55^2\)

The following coefficients must be defined for each bond type via the *bond_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( K \) (energy/distance^2)
- \( r_0 \) (distance)

21.9.4 Restrictions

</tr>
<tr>
<td>bond_style</td>
<td>oxrna2/fene</td>
<td>bond_coeff</td>
<td>2.0 0.25 0.76107</td>
</tr>
</tbody>
</table>

21.15.3 Description

The oxdna/fene, oxdna2/fene and oxrna2/fene bond styles use the potential

\[ E = -\frac{\epsilon}{2} \ln \left[ 1 - \left( \frac{r - r_0}{\Delta} \right)^2 \right] \]

to define a modified finite extensible nonlinear elastic (FENE) potential (Ouldridge) to model the connectivity of the phosphate backbone in the oxDNA/oxRNA force field for coarse-grained modelling of DNA/RNA.

The following coefficients must be defined for the bond type via the bond_coeff command as given in the above example, or in the data file or restart files read by the read_data or read_restart commands:
• \( \epsilon \) (energy)
• \( \Delta \) (distance)
• \( r_0 \) (distance)

Note: The oxDNA bond style has to be used together with the corresponding oxDNA pair styles for excluded volume interaction oxdna/excv, stacking oxdna/stk, cross-stacking oxdna/xstk and coaxial stacking interaction oxdna/coaxstk as well as hydrogen-bonding interaction oxdna/hbond (see also documentation of pair_style oxdna/excv). For the oxDNA2 (Snodin) bond style the analogous pair styles oxdna2/excv, oxdna2/stk, oxdna2/xstk, oxdna2/coaxstk, oxdna2/hbond and an additional Debye-Hueckel pair style oxdna2/dh have to be defined. The same applies to the oxRNA2 (Sulc1) styles. The coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model.

Example input and data files for DNA and RNA duplexes can be found in examples/USER/cgdna/examples/oxDNA/, /oxDNA2/ and /oxRNA2/. A simple python setup tool which creates single straight or helical DNA strands, DNA/RNA duplexes or arrays of DNA/RNA duplexes can be found in examples/USER/cgdna/util/.

Please cite (Henrich) in any publication that uses this implementation. The article contains general information on the model, its implementation and performance as well as the structure of the data and input file. The preprint version of the article can be found here. Please cite also the relevant oxDNA/oxRNA publications. These are (Ouldridge) and (Ouldridge-DPhil) for oxDNA, (Snodin) for oxDNA2, (Sulc1) for oxRNA2 and for sequence-specific hydrogen-bonding and stacking interactions (Sulc2).

21.15.4 Restrictions

This bond style can only be used if LAMMPS was built with the USER-CGDNA package and the MOLECULE and ASPHERE package. See the Build package doc page for more info.

21.15.5 Related commands

pair_style oxdna/excv, pair_style oxdna2/excv, pair_style oxrna2/excv, bond_coeff, fix nve/dotc/langevin

21.15.6 Default

none

21.15. bond_style oxrna2/fene command
21.16 bond_style quartic command

Accelerator Variants: quartic/omp

21.16.1 Syntax

```
bond_style quartic
```

21.16.2 Examples

```
bond_style quartic
bond_coeff 2 1200 -0.55 0.25 1.3 34.6878
```

21.16.3 Description

The quartic bond style uses the potential

\[
E = K(r - R_c)^2(r - R_c - B_1)(r - R_c - B_2) + U_0 + 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] + \epsilon
\]

to define a bond that can be broken as the simulation proceeds (e.g. due to a polymer being stretched). The \( \sigma \) and \( \epsilon \) used in the LJ portion of the formula are both set equal to 1.0 by LAMMPS.

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy/distance^4)
- \( B_1 \) (distance)
- \( B_2 \) (distance)
- \( R_c \) (distance)
- \( U_0 \) (energy)

This potential was constructed to mimic the FENE bond potential for coarse-grained polymer chains. When monomers with \( \sigma = \epsilon = 1.0 \) are used, the following choice of parameters gives a quartic potential that looks nearly like the FENE potential:

\[
K = 1200 \\
B_1 = -0.55 \\
B_2 = 0.25 \\
R_c = 1.3 \\
U_0 = 34.6878
\]

Different parameters can be specified using the `bond_coeff` command, but you will need to choose them carefully so they form a suitable bond potential.

\( R_c \) is the cutoff length at which the bond potential goes smoothly to a local maximum. If a bond length ever becomes \( > R_c \), LAMMPS “breaks” the bond, which means two things. First, the bond potential is turned off by setting its type to 0, and is no longer computed. Second, a pairwise interaction between the two atoms is turned on, since they are no longer bonded.
LAMMPS does the second task via a computational sleight-of-hand. It subtracts the pairwise interaction as part of the bond computation. When the bond breaks, the subtraction stops. For this to work, the pairwise interaction must always be computed by the `pair_style` command, whether the bond is broken or not. This means that `special_bonds` must be set to 1,1,1, as indicated as a restriction below.

Note that when bonds are dumped to a file via the `dump local` command, bonds with type 0 are not included. The `delete_bonds` command can also be used to query the status of broken bonds or permanently delete them, e.g.:

```bash
delete_bonds all stats
delete_bonds all bond 0 remove
```

Styles with a `gpu`, `intel`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

## 21.16.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

The `quartic` style requires that `special_bonds` parameters be set to 1,1,1. Three- and four-body interactions (angle, dihedral, etc) cannot be used with `quartic` bonds.

## 21.16.5 Related commands

`bond_coeff`, `delete_bonds`

## 21.16.6 Default

`none`

## 21.17 bond_style special command

### 21.17.1 Syntax

```bash
bond_style special
```
21.17.2 Examples

```
bond_style special
bond_coeff 0.5 0.5
```

21.17.3 Description

The `special` bond style can be used to create conceptual bonds which effectively impose weightings on the pairwise Lennard Jones and/or Coulombic interactions between selected pairs of particles in the system. The form of the pairwise interaction will be whatever is computed by the `pair_style` command defined for the system; this command defines the weightings for its two terms.

This command can thus be useful to apply weightings that cannot be handled by the `special_bonds` command, such as on 1-5 or 1-6 interactions. Or it can be used to add pairwise forces between one or more pairs of atoms that otherwise would not be included in the `pair_style` computation.

The potential for this bond style has the form

\[ E = w_{LJ}E_{LJ} + w_{Coul}E_{Coul} \]

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( w_{LJ} \) weight (0.0 to 1.0) on pairwise Lennard-Jones interactions
- \( w_{Coul} \) weight (0.0 to 1.0) on pairwise Coulombic interactions

Normally this bond style should be used in conjunction with one (or more) other bond styles which compute forces between atoms directly bonded to each other in a molecule. This means the `bond_style hybrid` command should be used with `bond_style special` as one of its sub-styles.

Note that the same as for any other bond style, pairs of bonded atoms must be enumerated in the data file read by the `read_data` command. Thus if this command is used to weight all 1-5 interactions in the system, all the 1-5 pairs of atoms must be listed in the “Bonds” section of the data file.

This bond style imposes strict requirements on settings made with the `special_bonds` command. These requirements ensure that the new bonds created by this style do not create spurious 1-2, 1-3, or 1-4 interactions within the molecular topology.

Specifically 1-2 interactions must have weights of zero, 1-3 interactions must either have weights of unity or `special_bonds angle yes` must be used, and 1-4 interactions must have weights of unity or `special_bonds dihedral yes` must be used.

If this command is used to create bonded interactions between particles that are further apart than usual (e.g. 1-5 or 1-6 interactions), this style may require an increase in the communication cutoff via the `comm_modify cutoff` command. If LAMMPS cannot find a partner atom in a bond, an error will be issued.
21.17.4 Restrictions

This bond style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

This bond style requires the use of a pair_style which computes a pairwise additive interaction and provides the ability to compute interactions for individual pairs of atoms. Manybody potentials are not compatible in general, but also some other pair styles are missing the required functionality and thus will cause an error.

This command is not compatible with long-range Coulombic interactions. If a kspace_style <kspace_style> is declared, an error will be issued.

21.17.5 Related commands

\texttt{bond\_coeff, special\_bonds}

21.17.6 Default

none

21.18 bond_style table command

Accelerator Variants: table/omp

21.18.1 Syntax

\begin{verbatim}
bond_style table style N
\end{verbatim}

- \texttt{style = linear or spline} = method of interpolation
- \texttt{N = use N values in table}

21.18.2 Examples

\begin{verbatim}
bond_style table linear 1000
bond_coeff 1 file.table ENTRY1
\end{verbatim}

21.18.3 Description

Style \texttt{table} creates interpolation tables of length \textit{N} from bond potential and force values listed in a file(s) as a function of bond length. The files are read by the \texttt{bond\_coeff} command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and force values at each of \textit{N} distances. During a simulation, these tables are used to interpolate energy and force values as needed. The interpolation is done in one of 2 styles: \texttt{linear} or \texttt{spline}.

For the \texttt{linear} style, the bond length is used to find 2 surrounding table values from which an energy or force is computed by linear interpolation.
For the \textit{spline} style, a cubic spline coefficients are computed and stored at each of the $N$ values in the table. The bond length is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

The following coefficients must be defined for each bond type via the \textit{bond_coeff} command as in the example above.

- \textit{filename}
- \textit{keyword}

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments):

\begin{verbatim}
# Bond potential for harmonic (one or more comment or blank lines)
HAM (keyword is the first text on line)
N 101 FP 0 0 EQ 0.5 (N, FP, EQ parameters)
1 0.00 338.0000 1352.0000 (index, bond-length, energy, force)
2 0.01 324.6152 1324.9600
...
101 1.00 338.0000 -1352.0000
\end{verbatim}

A section begins with a non-blank line whose first character is not a ‘#’; blank lines or lines starting with ‘#’ can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the \textit{bond_coeff} command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the $N$ specified in the \textit{bond_style table} command. Let \textit{Ntable} = $N$ in the \textit{bond_style command}, and \textit{Nfile} = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the \textit{Nfile} tabulated values as nodal points. It uses these to interpolate as needed to generate energy and force values at \textit{Ntable} different points. The resulting tables of length \textit{Ntable} are then used as described above, when computing energy and force for individual bond lengths. This means that if you want the interpolation tables of length \textit{Ntable} to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set \textit{Ntable} = \textit{Nfile}.

The “FP” parameter is optional. If used, it is followed by two values \textit{fplo} and \textit{fphi}, which are the derivatives of the force at the innermost and outermost bond lengths. These values are needed by the spline construction routines. If not specified by the “FP” parameter, they are estimated (less accurately) by the first two and last two force values in the table.

The “EQ” parameter is also optional. If used, it is followed by a the equilibrium bond length, which is used, for example, by the \textit{fix shake} command. If not used, the equilibrium bond length is to the distance in the table with the lowest potential energy.

Following a blank line, the next \textit{N} lines list the tabulated values. On each line, the first value is the index from 1 to \textit{N}, the second value is the bond length $r$ (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The bond lengths must range from a \textit{LO} value to a \textit{HI} value, and increase from one line to the next. If the actual bond length is ever smaller than the \textit{LO} value or larger than the \textit{HI} value, then the calculation is aborted with an error, so it is advisable to cover the whole range of possible bond lengths.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

---

**21.18.4 Restart, fix_modify, output, run start/stop, minimize info**

This bond style writes the settings for the “bond_style table” command to binary restart files, so a bond_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, bond_coeff commands do need to be specified in the restart input script.

**21.18.5 Restrictions**

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

**21.18.6 Related commands**

`bond_coeff`, `delete_bonds`

**21.18.7 Default**

`none`

---

**21.19 bond_style zero command**

**21.19.1 Syntax**

```
bond_style zero [nocoeff]
```
### 21.19.2 Examples

```plaintext
bond_style zero
bond_style zero nocoeff
bond_coeff *
  bond_coeff = 2.14
```

### 21.19.3 Description

Using an bond style of zero means bond forces and energies are not computed, but the geometry of bond pairs is still accessible to other commands.

As an example, the `compute bond/local` command can be used to compute distances for the list of pairs of bond atoms listed in the data file read by the `read_data` command. If no bond style is defined, this command cannot be used.

The optional `nocoeff` flag allows to read data files with a BondCoeff section for any bond style. Similarly, any `bond_coeff` commands will only be checked for the bond type number and the rest ignored.

Note that the `bond_coeff` command must be used for all bond types. If specified, there can be only one value, which is going to be used to assign an equilibrium distance, e.g. for use with `fix shake`.

### 21.19.4 Restrictions

- none

### 21.19.5 Related commands

- `bond_style none`

### 21.19.6 Default

22.1 angle_style charmm command

Accelerator Variants: charmm/intel, charmm/kk, charmm/omp

22.1.1 Syntax

```
angle_style charmm
```

22.1.2 Examples

```
angle_style charmm
angle_coeff 1 300.0 107.0 50.0 3.0
```

22.1.3 Description

The `charmm` angle style uses the potential

\[ E = K(\theta - \theta_0)^2 + K_{ub}(r - r_{ub})^2 \]

with an additional Urey_Bradley term based on the distance \( r \) between the first and third atoms in the angle. \( K, \theta_0, K_{ub}, \) and \( R_{ub} \) are coefficients defined for each angle type.

See (MacKerell) for a description of the CHARMM force field.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy)
- \( \theta_0 \) (degrees)
- \( K_{ub} \) (energy/distance^2)
- \( r_{ub} \) (distance)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence \( K \) is effectively energy per radian^2.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages.
doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

22.1.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

22.1.5 Related commands

angle_coeff

22.1.6 Default

none

22.2 angle_style class2 command

Accelerator Variants: class2/kk, class2/omp

22.3 angle_style class2/p6 command

22.3.1 Syntax

```plaintext
angle_style class2
```
22.3.2 Examples

```
angle_style class2
angle_coeff * 75.0
angle_coeff 1 bb 10.5872 1.0119 1.5228
angle_coeff * ba 3.6551 24.895 1.0119 1.5228
```

22.3.3 Description

The class2 angle style uses the potential

\[ E = E_a + E_{bb} + E_{ba} \]

\[ E_a = K_2(\theta - \theta_0)^2 + K_3(\theta - \theta_0)^3 + K_4(\theta - \theta_0)^4 \]

\[ E_{bb} = M(r_{ij} - r_1)(r_{jk} - r_2) \]

\[ E_{ba} = N_1(r_{ij} - r_1)(\theta - \theta_0) + N_2(r_{jk} - r_2)(\theta - \theta_0) \]

where \( E_a \) is the angle term, \( E_{bb} \) is a bond-bond term, and \( E_{ba} \) is a bond-angle term. \( \theta_0 \) is the equilibrium angle and \( r_1 \) and \( r_2 \) are the equilibrium bond lengths.

See (Sun) for a description of the COMPASS class2 force field.

Coefficients for the \( E_a \), \( E_{bb} \), and \( E_{ba} \) formulas must be defined for each angle type via the angle_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands.

These are the 4 coefficients for the \( E_a \) formula:

- \( \theta_0 \) (degrees)
- \( K_2 \) (energy)
- \( K_3 \) (energy)
- \( K_4 \) (energy)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence the various \( K \) are effectively energy per radian^2 or radian^3 or radian^4.

For the \( E_{bb} \) formula, each line in a angle_coeff command in the input script lists 4 coefficients, the first of which is “bb” to indicate they are BondBond coefficients. In a data file, these coefficients should be listed under a “BondBond Coeffs” heading and you must leave out the “bb”, i.e. only list 3 coefficients after the angle type.

- bb
- \( M \) (energy/distance^2)
- \( r_1 \) (distance)
- \( r_2 \) (distance)

For the \( E_{ba} \) formula, each line in a angle_coeff command in the input script lists 5 coefficients, the first of which is “ba” to indicate they are BondAngle coefficients. In a data file, these coefficients should be listed under a “BondAngle Coeffs” heading and you must leave out the “ba”, i.e. only list 4 coefficients after the angle type.

- ba
- \( N_1 \) (energy/distance^2)
- \( N_2 \) (energy/distance^2)
- \( r_1 \) (distance)
- \( r_2 \) (distance)
The $\theta_0$ value in the $E_{ba}$ formula is not specified, since it is the same value from the $E_a$ formula.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

The class2/p6 angle style uses the class2 potential expanded to sixth order:

$$E_a = K_2 (\theta - \theta_0)^2 + K_3 (\theta - \theta_0)^3 + K_4 (\theta - \theta_0)^4 + K_5 (\theta - \theta_0)^5 + K_6 (\theta - \theta_0)^6$$

In this expanded term 6 coefficients for the $E_a$ formula need to be set:

- $\theta_0$ (degrees)
- $K_2$ (energy)
- $K_3$ (energy)
- $K_4$ (energy)
- $K_5$ (energy)
- $K_6$ (energy)

$\theta_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence the various $K$ are effectively energy per radian$^2$ or radian$^3$ or radian$^4$ or radian$^5$ or radian$^6$.

The bond-bond and bond-angle terms remain unchanged.

### 22.3.4 Restrictions

This angle style can only be used if LAMMPS was built with the CLASS2 package. For the class2/p6 style LAMMPS needs to be built with the USER-MOFFF package. See the Build package doc page for more info.

22.5 angle_style cosine/buck6d command

22.5.1 Syntax

```
angle_style cosine/buck6d
```

22.5.2 Examples

```
angle_style cosine/buck6d
angle_coeff 1 cosine/buck6d 1.978350 4 180.000000
```

22.5.3 Description

The `cosine/buck6d` angle style uses the potential

\[ E = K \left[ 1 + \cos(n\theta - \theta_0) \right] \]

where \( K \) is the energy constant, \( n \) is the periodic multiplicity and \( \theta_0 \) is the equilibrium angle.

The coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands in the following order:

- \( K \) (energy)
- \( n \)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally.

Additional to the cosine term the `cosine/buck6d` angle style computes the short range (vdW) interaction belonging to the `pair_style buck6d` between the end atoms of the angle. For this reason this angle style only works in combination with the `pair_style buck6d` styles and needs the `special_bonds` 1-3 interactions to be weighted 0.0 to prevent double counting.
22.5.4 Restrictions

cosine/buck6d can only be used in combination with the pair_style buck6d style and with a special_bonds 0.0 weighting of 1-3 interactions.

This angle style can only be used if LAMMPS was built with the USER-MOFFF package. See the Build package doc page for more info.

22.7 angle_style cosine/periodic command

Accelerator Variants: cosine/periodic/omp

22.7.1 Syntax

angle_style cosine/periodic

22.7.2 Examples

angle_style cosine/periodic
angle_coeff 75.0 1 6
22.7.3 Description

The *cosine/periodic* angle style uses the following potential, which is commonly used in the *DREIDING* force field, particularly for organometallic systems where \( n = 4 \) might be used for an octahedral complex and \( n = 3 \) might be used for a trigonal center:

\[
E = C \left[ 1 - B(-1)^n \cos (n \theta) \right]
\]

where \( C \), \( B \) and \( n \) are coefficients defined for each angle type.

See [Mayo] for a description of the DREIDING force field.

The following coefficients must be defined for each angle type via the *angle_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( C \) (energy)
- \( B = 1 \) or -1
- \( n = 1, 2, 3, 4, 5 \) or 6 for periodicity

Note that the prefactor \( C \) is specified and not the overall force constant \( K = \frac{C}{n^2} \). When \( B = 1 \), it leads to a minimum for the linear geometry. When \( B = -1 \), it leads to a maximum for the linear geometry.

Styles with a *gpu, intel, kk, omp, or opt* suffix are functionally the same as the corresponding style without the suffix. 22.9.1 Syntax

\texttt{angle_style cosine/shift/exp}

22.9.2 Examples

\texttt{angle_style cosine/shift/exp}
\texttt{angle_coeff \ast 10.0 45.0 2.0}

22.9.3 Description

The \textit{cosine/shift/exp} angle style uses the potential

\[ E = -U_{\text{min}} \frac{e^{-aU(\theta, \theta_0)} - 1}{e^a - 1} \quad \text{with} \quad U(\theta, \theta_0) = -0.5 (1 + \cos(\theta - \theta_0)) \]

where \( U_{\text{min}}, \theta, \) and \( a \) are defined for each angle type.

The potential is bounded between \([-U_{\text{min}}, 0]\) and the minimum is located at the angle \( \theta_0 \). The \( a \) parameter can be both positive or negative and is used to control the spring constant at the equilibrium.

The spring constant is given by \( k = A \exp(A)U_{\text{min}}/[2(\exp(a) - 1)] \). For \( a > 3 \), \( \frac{k}{U_{\text{min}}} = \frac{a^2}{2} \) to better than 5% relative error. For negative values of the \( a \) parameter, the spring constant is essentially zero, and anharmonic terms take over.

The potential is furthermore well behaved in the limit \( a \rightarrow 0 \), where it has been implemented to linear order in \( a \) for \( a < 0.001 \). In this limit the potential reduces to the cosineshifted potential.

The following coefficients must be defined for each angle type via the \texttt{angle_coeff} command as in the example above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands:

- \( U_{\text{min}} \) (energy)
- \( \theta \) (angle)
- \( A \) (real number)
Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Speed packages* doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the *Speed packages* doc page for more instructions on how to use the accelerated styles effectively.

### 22.9.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER-MISC package. See the *Build package* doc page for more info.

### 22.9.5 Related commands

`angle_coeff, angle_style cosine/shift, dihedral_style cosine/shift/exp`

### 22.9.6 Default

`none`

### 22.10 angle_style cosine/squared command

**Accelerator Variants:** *cosine/squared/omp*

#### 22.10.1 Syntax

```
angle_style  cosine/squared
```

#### 22.10.2 Examples

```
angle_style cosine/squared
angle_coeff 2 4 75.0 100.0
```
22.10.3 Description

The cosine/squared angle style uses the potential

\[ E = K(\cos(\theta) - \cos(\theta_0))^2 \]

where \( \theta_0 \) is the equilibrium value of the angle, and \( K \) is a prefactor. Note that the usual 1/2 factor is included in \( K \).

The following coefficients must be defined for each angle type via the \texttt{angle_coeff} command as in the example above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands:

- \( K \) (energy)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

22.10.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the \texttt{Build package} doc page for more info.

22.10.5 Related commands

\texttt{angle_coeff}

22.10.6 Default

none

22.11 angle_style cross command

22.11.1 Syntax

\texttt{angle_style cross}
22.11.2 Examples

\begin{verbatim}
angle_style cross
angle_coeff 1 200.0 100.0 100.0 1.25 1.25 107.0
\end{verbatim}

22.11.3 Description

The `cross` angle style uses a potential that couples the bond stretches of a bend with the angle stretch of that bend:

\[ E = K_{SS} (r_{12} - r_{12,0}) (r_{32} - r_{32,0}) + K_{BS0} (r_{12} - r_{12,0}) (\theta - \theta_0) + K_{BS1} (r_{32} - r_{32,0}) (\theta - \theta_0) \]

where \( r_{12,0} \) is the rest value of the bond length between atom 1 and 2, \( r_{32,0} \) is the rest value of the bond length between atom 3 and 2, and \( \theta_0 \) is the rest value of the angle. \( K_{SS} \) is the force constant of the bond stretch-bond stretch term and \( K_{BS0} \) and \( K_{BS1} \) are the force constants of the bond stretch-angle stretch terms.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K_{SS} \) (energy/distance^2)
- \( K_{BS0} \) (energy/distance)
- \( K_{BS1} \) (energy/distance)
- \( r_{12,0} \) (distance)
- \( r_{32,0} \) (distance)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence the \( K_{BS0} \) and \( K_{BS1} \) are effectively energy/distance per radian.

22.11.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER_YAFF package. See the `Build package` doc page for more info.

22.11.5 Related commands

`angle_coeff`

22.11.6 Default

22.12 angle_style dipole command

Accelerator Variants: dipole/omp

22.12.1 Syntax

```
angle_style dipole
```

22.12.2 Examples

```
angle_style dipole
angle_coeff 6 2.1 180.0
```

22.12.3 Description

The dipole angle style is used to control the orientation of a dipolar atom within a molecule (Orsi). Specifically, the dipole angle style restrains the orientation of a point dipole $\mu_j$ (embedded in atom $j$) with respect to a reference (bond) vector $r_{ij}^* = r_i^* - r_j^*$, where $i$ is another atom of the same molecule (typically, $i$ and $j$ are also covalently bonded).

It is convenient to define an angle gamma between the ‘free’ vector $\vec{\mu}_j$ and the reference (bond) vector $\vec{r}_{ij}$:

$$
\cos \gamma = \frac{\vec{\mu}_j \cdot \vec{r}_{ij}}{\mu_j r_{ij}}
$$

The dipole angle style uses the potential:

$$
E = K(\cos \gamma - \cos \gamma_0)^2
$$

where $K$ is a rigidity constant and $\gamma_0$ is an equilibrium (reference) angle.

The torque on the dipole can be obtained by differentiating the potential using the ‘chain rule’ as in appendix C.3 of (Allen):

$$
\vec{T}_j = 2K(\cos \gamma - \cos \gamma_0) \frac{\mu_j r_{ij}}{r_{ij}^* \times \vec{\mu}_j}
$$

Example: if $\gamma_0$ is set to 0 degrees, the torque generated by the potential will tend to align the dipole along the reference direction defined by the (bond) vector $r_{ij}^*$ (in other words, $\mu_j^*$ is restrained to point towards atom $i$).

The dipolar torque $\vec{T}_j$ must be counterbalanced in order to conserve the local angular momentum. This is achieved via an additional force couple generating a torque equivalent to the opposite of $\vec{T}_j$:

$$
-T_j = r_{ij}^* \times \vec{F}_i
$$

where $\vec{F}_i$ and $\vec{F}_j$ are applied on atoms $i$ and $j$, respectively.

The following coefficients must be defined for each angle type via the angle_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- $K$ (energy)
- $\gamma_0$ (degrees)
Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 22.12.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

**Note:** In the “Angles” section of the data file, the atom ID *j* defining the direction of the dipole vector to restrain must come before the atom ID of the reference atom *i*. A third atom ID *k* must also be provided to comply with the requirement of a valid angle definition. This atom ID *k* should be chosen to be that of an atom bonded to atom *i* to avoid errors with “lost angle atoms” when running in parallel. Since the LAMMPS code checks for valid angle definitions, cannot use the same atom ID of either *i* or *j* (this was allowed and recommended with older LAMMPS versions).

The `newton` command for intramolecular interactions must be “on” (which is the default except when using some accelerator packages).

This angle style should not be used with SHAKE.

### 22.15.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

### 22.15.5 Related commands

`angle_coeff`

### 22.15.6 Default

none

### 22.16 angle_style hybrid command

#### 22.16.1 Syntax

```
angle_style hybrid style1 style2 ...
```

- style1.style2 = list of one or more angle styles

#### 22.16.2 Examples

```
angle_style hybrid harmonic cosine
angle_coeff 1 harmonic 80.0 30.0
angle_coeff 2* cosine 50.0
```
22.16.3 Description

The hybrid style enables the use of multiple angle styles in one simulation. An angle style is assigned to each angle type. For example, angles in a polymer flow (of angle type 1) could be computed with a harmonic potential and angles in the wall boundary (of angle type 2) could be computed with a cosine potential. The assignment of angle type to style is made via the angle_coeff command or in the data file.

In the angle_coeff commands, the name of an angle style must be added after the angle type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 angle_coeff commands set angles of angle type 1 to be computed with a harmonic potential with coefficients 80.0, 30.0 for $K$, $\theta_0$. All other angle types ($2 - N$) are computed with a cosine potential with coefficient 50.0 for $K$.

If angle coefficients are specified in the data file read via the read_data command, then the same rule applies. E.g. “harmonic” or “cosine”, must be added after the angle type, for each line in the “Angle Coeffs” section, e.g.

```
Angle Coeffs
1 harmonic 80.0 30.0
2 cosine 50.0
...
```

If class2 is one of the angle hybrid styles, the same rule holds for specifying additional BondBond (and BondAngle) coefficients either via the input script or in the data file. I.e. class2 must be added to each line after the angle type. For lines in the BondBond (or BondAngle) section of the data file for angle types that are not class2, you must use an angle style of skip as a placeholder, e.g.

```
BondBond Coeffs
1 skip
2 class2 3.6512 1.0119 1.0119
...
```

Note that it is not necessary to use the angle style skip in the input script, since BondBond (or BondAngle) coefficients need not be specified at all for angle types that are not class2.

An angle style of none with no additional coefficients can be used in place of an angle style, either in a input script angle_coeff command or in the data file, if you desire to turn off interactions for specific angle types.

22.16.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

Unlike other angle styles, the hybrid angle style does not store angle coefficient info for individual sub-styles in a binary restart files. Thus when restarting a simulation from a restart file, you need to re-specify angle_coeff commands.
22.16.5 Related commands

angle_coeff

22.17 angle_style mm3 command

22.17.1 Syntax

angle_style mm3

22.17.2 Examples

angle_style mm3
angle_coeff 1 100.0 107.0

22.17.3 Description

The mm3 angle style uses the potential that is anharmonic in the angle as defined in (Allinger)

\[ E = K (\theta - \theta_0)^2 \left[ 1 - 0.014(\theta - \theta_0) + 5.6(10)^{-5}(\theta - \theta_0)^2 - 7.0(10)^{-7}(\theta - \theta_0)^3 + 9(10)^{-10}(\theta - \theta_0)^4 \right] \]

where \(\theta_0\) is the equilibrium value of the angle, and \(K\) is a prefactor. The anharmonic prefactors have units \(\text{deg}^{-n}\), for example \(-0.014 \text{ deg}^{-1}\), \(5.6 \cdot 10^{-5} \text{ deg}^{-2}\), . . .

The following coefficients must be defined for each angle type via the angle_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \(K\) (energy)
- \(\theta_0\) (degrees)

\(\theta_0\) is specified in degrees, but LAMMPS converts it to radians internally; hence \(K\) is effectively energy per radian^2.

22.17.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER_YAFF package. See the Build package doc page for more info.

```

22.19.2 Examples

```plaintext
angle_style quartic
angle_coeff 1 129.1948 56.8726 -25.9442 -14.2221
```

22.19.3 Description

The quartic angle style uses the potential

\[ E = K_2(\theta - \theta_0)^2 + K_3(\theta - \theta_0)^3 + K_4(\theta - \theta_0)^4 \]

where \( \theta_0 \) is the equilibrium value of the angle, and \( K \) is a prefactor. Note that the usual 1/2 factor is included in \( K \). The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( \theta_0 \) (degrees)
- \( K_2 \) (energy)
- \( K_3 \) (energy)
- \( K_4 \) (energy)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence the various \( K \) are effectively energy per radian^2 or radian^3 or radian^4.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

22.20.1 Syntax

angle_style  sdk
angle_style  sdk/omp

22.20.2 Examples

angle_style  sdk
angle_coeff  1 300.0 107.0

22.20.3 Description

The *sdk* angle style is a combination of the harmonic angle potential,

\[ E = K(\theta - \theta_0)^2 \]

where \( \theta_0 \) is the equilibrium value of the angle and \( K \) a prefactor, with the repulsive part of the non-bonded *lj/sdk* pair style between the atoms 1 and 3. This angle potential is intended for coarse grained MD simulations with the CMM parameterization using the *pair_style lj/sdk*. Relative to the pair_style *lj/sdk*, however, the energy is shifted by \( \epsilon \), to avoid sudden jumps. Note that the usual 1/2 factor is included in \( K \).

The following coefficients must be defined for each angle type via the *angle_coeff* command as in the example above:

- \( K \) (energy)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence \( K \) is effectively energy per radian^2.

The required *lj/sdk* parameters are extracted automatically from the *pair_style*. 

22.20. angle_style sdk command
Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

\subsection{22.21 \textit{angle_style} table command}
Accelerator Variants: \textit{table/omp}

\subsubsection{22.21.1 Syntax}
\begin{verbatim}
angle_style table style N
\end{verbatim}

- \textit{style} = \texttt{linear} or \texttt{spline} = method of interpolation
- \textit{N} = use \textit{N} values in table

\subsubsection{22.21.2 Examples}
\begin{verbatim}
angle_style table linear 1000
angle_coeff 3 file.table ENTRY1
\end{verbatim}
22.21.3 Description

Style *table* creates interpolation tables of length \(N\) from angle potential and derivative values listed in a file(s) as a function of angle. The files are read by the `angle_coeff` command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and derivative values at each of \(N\) angles. During a simulation, these tables are used to interpolate energy and force values on individual atoms as needed. The interpolation is done in one of 2 styles: *linear* or *spline*.

For the *linear* style, the angle is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation.

For the *spline* style, a cubic spline coefficients are computed and stored at each of the \(N\) values in the table. The angle is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or derivative.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above.

- filename
- keyword

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# Angle potential for harmonic (one or more comment or blank lines)
HAM                                           (keyword is the first text on line)
N 181 FP 0 0 EQ 90.0                          (N, FP, EQ parameters)
    (blank line)
N 181 FP 0 0                                 (N, FP parameters)
    1 0.0 200.5 2.5                           (index, angle, energy, derivative)
    2 1.0 198.0 2.5                           ...
    181 180.0 0.0 0.0                         

```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the `angle_coeff` command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “\(N\)” is required and its value is the number of table entries that follow. Note that this may be different than the \(N\) specified in the `angle_style table` command. Let \(N_{\text{table}} = N\) in the `angle_style` command, and \(N_{\text{file}} = \text{“}N\text{”} in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the \(N_{\text{file}}\) tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at \(N_{\text{table}}\) different points. The resulting tables of length \(N_{\text{table}}\) are then used as described above, when computing energy and force for individual angles and their atoms. This means that if you want the interpolation tables of length \(N_{\text{table}}\) to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set \(N_{\text{table}} = N_{\text{file}}\).

The “FP” parameter is optional. If used, it is followed by two values \(f_{\text{plo}}\) and \(f_{\text{phi}}\), which are the second derivatives at the innermost and outermost angle settings. These values are needed by the spline construction routines. If not specified by the “FP” parameter, they are estimated (less accurately) by the first two and last two derivative values in the table.

The “EQ” parameter is also optional. If used, it is followed by a the equilibrium angle value, which is used, for example, by the `fix shake` command. If not used, the equilibrium angle is set to 180.0.
Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the angle value (in degrees), the third value is the energy (in energy units), and the fourth is \(-\frac{dE}{d(\theta)}\) (also in energy units). The third term is the energy of the 3-atom configuration for the specified angle. The last term is the derivative of the energy with respect to the angle (in degrees, not radians). Thus the units of the last term are still energy, not force. The angle values must increase from one line to the next. The angle values must also begin with 0.0 and end with 180.0, i.e. span the full range of possible angles.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

Styles with a `gpu`, `intel`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

22.21.4 Restart, fix_modify, output, run start/stop, minimize info

This angle style writes the settings for the “angle_style table” command to binary restart files, so a angle_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, angle_coeff commands do need to be specified in the restart input script.

22.21.5 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

22.21.6 Related commands

`angle_coeff`

22.21.7 Default

none
22.22 angle_style zero command

22.22.1 Syntax

```
angle_style zero *nocoeff*
```

22.22.2 Examples

```
angle_style zero
angle_style zero nocoeff
angle_coeff *
angle_coeff * 120.0
```

22.22.3 Description

Using an angle style of zero means angle forces and energies are not computed, but the geometry of angle triplets is still accessible to other commands.

As an example, the `compute angle/local` command can be used to compute the theta values for the list of triplets of angle atoms listed in the data file read by the `read_data` command. If no angle style is defined, this command cannot be used.

The optional `nocoeff` flag allows to read data files with AngleCoeff section for any angle style. Similarly, any `angle_coeff` commands will only be checked for the angle type number and the rest ignored.

Note that the `angle_coeff` command must be used for all angle types. If specified, there can be only one value, which is going to be used to assign an equilibrium angle, e.g. for use with `fix shake`.

CHAPTER TWENTYTHREE

DIHEDRAL STYLES

23.1 dihedral_style charmm command

Accelerator Variants: charmm/intel, charmm/kk, charmm/omp

23.2 dihedral_style charmmfsw command

23.2.1 Syntax

\begin{verbatim}
dihedral_style style

  • style = charmm or charmmfsw
\end{verbatim}

23.2.2 Examples

\begin{verbatim}
dihedral_style charmm

dihedral_style charmmfsw
  dihedral_coeffige 1 0.2 1 180 1.0
  dihedral_coeffige 2 1.8 1 0 1.0
  dihedral_coeffige 1 3.1 2 180 0.5
\end{verbatim}

23.2.3 Description

The \textit{charmm} and \textit{charmmfsw} dihedral styles use the potential

\[ E = K[1 + \cos(n\phi - d)] \]

See \cite{MacKerell} for a description of the CHARMM force field. This dihedral style can also be used for the AMBER force field (see comment on weighting factors below). See \cite{Cornell} for a description of the AMBER force field.

\textbf{Note:} The newer \textit{charmmfsw} style was released in March 2017. We recommend it be used instead of the older \textit{charmm} style when running a simulation with the CHARMM force field, either with long-range Coulombics or a Coulombic cutoff, via the \texttt{pair_style lj/charmmfsw/coul/long} and \texttt{pair_style lj/charmmfsw/coul/charmmfsh} commands respectively. Otherwise the older \textit{charmm} style is fine to use. See the discussion below and more details on the \texttt{pair_style charmm} doc page.
The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy)
- \( n \) (integer \( \geq 0 \))
- \( d \) (integer value of degrees)
- weighting factor (1.0, 0.5, or 0.0)

The weighting factor is required to correct for double counting pairwise non-bonded Lennard-Jones interactions in cyclic systems or when using the CHARMM dihedral style with non-CHARMM force fields. With the CHARMM dihedral style, interactions between the first and fourth atoms in a dihedral are skipped during the normal non-bonded force computation and instead evaluated as part of the dihedral using special epsilon and sigma values specified with the `pair_coeff` command of pair styles that contain “lj/charmm” (e.g. `pair_style lj/charmm/coul/long`). In 6-membered rings, the same 1-4 interaction would be computed twice (once for the clockwise 1-4 pair in dihedral 1-2-3-4 and once in the counterclockwise dihedral 1-6-5-4) and thus the weighting factor has to be 0.5 in this case. In 4-membered or 5-membered rings, the 1-4 dihedral also is counted as a 1-2 or 1-3 interaction when going around the ring in the opposite direction and thus the weighting factor is 0.0, as the 1-2 and 1-3 exclusions take precedence.

Note that this dihedral weighting factor is unrelated to the scaling factor specified by the `special_bonds` command which applies to all 1-4 interactions in the system. For CHARMM force fields, the `special_bonds` 1-4 interaction scaling factor should be set to 0.0. Since the corresponding 1-4 non-bonded interactions are computed with the dihedral. This means that if any of the weighting factors defined as dihedral coefficients (fourth coeff above) are non-zero, then you must use a pair style with “lj/charmm” and set the `special_bonds` 1-4 scaling factor to 0.0 (which is the default). Otherwise 1-4 non-bonded interactions in dihedrals will be computed twice.

For simulations using the CHARMM force field with a Coulombic cutoff, the difference between the `charmm` and `charmmfsw` styles is in the computation of the 1-4 non-bond interactions, though only if the distance between the two atoms is within the switching region of the pairwise potential defined by the corresponding CHARMM pair style, i.e. within the outer cutoff specified for the pair style. The `charmmfsw` style should only be used when using the corresponding `pair_style lj/charmmfsw/coul/charmmfsw` or `pair_style lj/charmmfsw/coul/long` commands. Use the `charmm` style with the older `pair_style` commands that have just “charmm” in their style name. See the discussion on the CHARMM `pair_style` doc page for details.

Note that for AMBER force fields, which use pair styles with “lj/cut”, the `special_bonds` 1-4 scaling factor should be set to the AMBER defaults (1/2 and 5/6) and all the dihedral weighting factors (fourth coeff above) must be set to 0.0. In this case, you can use any pair style you wish, since the dihedral does not need any Lennard-Jones parameter information and will not compute any 1-4 non-bonded interactions. Likewise the `charmm` or `charmmfsw` styles are identical in this case since no 1-4 non-bonded interactions are computed.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
23.2.4 Restrictions

When using run_style respa, these dihedral styles must be assigned to the same r-RESPA level as pair or outer.

When used in combination with CHARMM pair styles, the 1-4 special_bonds scaling factors must be set to 0.0. Otherwise non-bonded contributions for these 1-4 pairs will be computed multiple times.

These dihedral styles can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

```
23.3.3 Description

The class2 dihedral style uses the potential

\[ E = E_d + E_{mbt} + E_{ebt} + E_{at} + E_{aat} + E_{bb13} \]

\[ E_d = \sum_{n=1}^{3} K_n [1 - \cos(n\phi - \phi_n)] \]

\[ E_{mbt} = (r_{jk} - r_2)[A_1 \cos(\phi) + A_2 \cos(2\phi) + A_3 \cos(3\phi)] + (r_{kl} - r_3)[C_1 \cos(\phi) + C_2 \cos(2\phi) + C_3 \cos(3\phi)] \]

\[ E_{ebt} = (r_{ij} - r_1)[B_1 \cos(\phi) + B_2 \cos(2\phi) + B_3 \cos(3\phi)] + (r_{kl} - r_3)[C_1 \cos(\phi) + C_2 \cos(2\phi) + C_3 \cos(3\phi)] \]

\[ E_{at} = (\theta_{ijk} - \theta_1)[D_1 \cos(\phi) + D_2 \cos(2\phi) + D_3 \cos(3\phi)] + (\theta_{jkl} - \theta_2)[E_1 \cos(\phi) + E_2 \cos(2\phi) + E_3 \cos(3\phi)] \]

\[ E_{aat} = M(\theta_{ijk} - \theta_1)(\theta_{jkl} - \theta_2) \cos(\phi) \]

\[ E_{bb13} = N(r_{ij} - r_1)(r_{kl} - r_3) \]

where \( E_d \) is the dihedral term, \( E_{mbt} \) is a middle-bond-torsion term, \( E_{ebt} \) is an end-bond-torsion term, \( E_{at} \) is an angle-torsion term, \( E_{aat} \) is an angle-angle-torsion term, and \( E_{bb13} \) is a bond-bond-13 term.

\( \theta_1 \) and \( \theta_2 \) are equilibrium angles and \( r_1, r_2, \) and \( r_3 \) are equilibrium bond lengths.

See (Sun) for a description of the COMPASS class2 force field.

Coefficients for the \( E_d \), \( E_{mbt} \), \( E_{ebt} \), \( E_{at} \), \( E_{aat} \), and \( E_{bb13} \) formulas must be defined for each dihedral type via the dihedral_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands.

These are the 6 coefficients for the \( E_d \) formula:

- \( K_1 \) (energy)
- \( \phi_1 \) (degrees)
- \( K_2 \) (energy)
- \( \phi_2 \) (degrees)
- \( K_3 \) (energy)
- \( \phi_3 \) (degrees)

For the \( E_{mbt} \) formula, each line in a dihedral_coeff command in the input script lists 5 coefficients, the first of which is \( mbt \) to indicate they are MiddleBondTorsion coefficients. In a data file, these coefficients should be listed under a MiddleBondTorsion Coeffs heading and you must leave out the \( mbt \), i.e. only list 4 coefficients after the dihedral type.

- \( mbt \)
- \( A_1 \) (energy/distance)
- \( A_2 \) (energy/distance)
- \( A_3 \) (energy/distance)
- \( r_2 \) (distance)

For the \( E_{ebt} \) formula, each line in a dihedral_coeff command in the input script lists 9 coefficients, the first of which is \( ebt \) to indicate they are EndBondTorsion coefficients. In a data file, these coefficients should be listed under a EndBondTorsion Coeffs heading and you must leave out the \( ebt \), i.e. only list 8 coefficients after the dihedral type.

- \( ebt \)
- \( B_1 \) (energy/distance)
• $B_2$ (energy/distance)
• $B_3$ (energy/distance)
• $C_1$ (energy/distance)
• $C_2$ (energy/distance)
• $C_3$ (energy/distance)
• $r_1$ (distance)
• $r_3$ (distance)

For the $E_{at}$ formula, each line in a `dihedral_coeff` command in the input script lists 9 coefficients, the first of which is $at$ to indicate they are AngleTorsion coefficients. In a data file, these coefficients should be listed under a `AngleTorsion Coeffs` heading and you must leave out the $at$, i.e. only list 8 coefficients after the dihedral type.

• $at$
• $D_1$ (energy)
• $D_2$ (energy)
• $D_3$ (energy)
• $E_1$ (energy)
• $E_2$ (energy)
• $E_3$ (energy)
• $\theta_1$ (degrees)
• $\theta_2$ (degrees)

$\theta_1$ and $\theta_2$ are specified in degrees, but LAMMPS converts them to radians internally; hence the various $D$ and $E$ are effectively energy per radian.

For the $E_{aat}$ formula, each line in a `dihedral_coeff` command in the input script lists 4 coefficients, the first of which is $aat$ to indicate they are AngleAngleTorsion coefficients. In a data file, these coefficients should be listed under a `AngleAngleTorsion Coeffs` heading and you must leave out the $aat$, i.e. only list 3 coefficients after the dihedral type.

• $aat$
• $M$ (energy)
• $\theta_1$ (degrees)
• $\theta_2$ (degrees)

$\theta_1$ and $\theta_2$ are specified in degrees, but LAMMPS converts them to radians internally; hence $M$ is effectively energy per radian^2.

For the $E_{bb13}$ formula, each line in a `dihedral_coeff` command in the input script lists 4 coefficients, the first of which is $bb13$ to indicate they are BondBond13 coefficients. In a data file, these coefficients should be listed under a `BondBond13 Coeffs` heading and you must leave out the $bb13$, i.e. only list 3 coefficients after the dihedral type.

• $bb13$
• $N$ (energy/distance^2)
• $r_1$ (distance)
• $r_3$ (distance)
Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

### 23.4 \texttt{dihedral_style cosine/shift/exp} command

Accelerator Variants: \textit{cosine/shift/exp/omp}

#### 23.4.1 Syntax

\texttt{dihedral_style cosine/shift/exp}

#### 23.4.2 Examples

\begin{verbatim}
  dihedral_style cosine/shift/exp
dihedral_coeff 1 10.0 45.0 2.0
\end{verbatim}
23.4.3 Description

The \textit{cosine/shift/exp} dihedral style uses the potential

\[ E = -U_{\text{min}} \frac{e^{-aU(\theta, \theta_0)} - 1}{e^a - 1} \quad \text{with} \quad U(\theta, \theta_0) = -0.5 (1 + \cos(\theta - \theta_0)) \]

where \(U_{\text{min}}\), \(\theta\), and \(a\) are defined for each dihedral type.

The potential is bounded between \([-U_{\text{min}} : 0]\) and the minimum is located at the angle \(\theta_0\). The \(a\) parameter can be both positive or negative and is used to control the spring constant at the equilibrium.

The spring constant is given by

\[ k = ae^a \frac{U_{\text{min}}}{2(e^a - 1)}. \]

For \(a > 3\) and \(\frac{k}{U_{\text{min}}^2} = \frac{a}{2}\) to better than 5% relative error. For negative values of the \(a\) parameter, the spring constant is essentially zero, and anharmonic terms take over. The potential is furthermore well behaved in the limit \(a \to 0\), where it has been implemented to linear order in \(a\) for \(a < 0.001\).

The following coefficients must be defined for each dihedral type via the \textit{dihedral_coeff} command as in the example above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands:

- \(U_{\text{min}}\) (energy)
- \(\theta\) (angle)
- \(a\) (real number)

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages} doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{--suffix} command-line switch when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Speed packages} doc page for more instructions on how to use the accelerated styles effectively.

23.4.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the USER-MISC package. See the \textit{Build package} doc page for more info.

23.5 dihedral_style fourier command

Accelerator Variants: fourier/intel, fourier/omp

23.5.1 Syntax

```
dihedral_style fourier
```

23.5.2 Examples

```
dihedral_style fourier
dihedral_coeff 1 3 -0.846200 3 0.0 7.578800 1 0 0.138000 2 -180.0
```

23.5.3 Description

The `fourier` dihedral style uses the potential:

\[
E = \sum_{i=1,m} K_i [1.0 + \cos(n_i \phi - d_i)]
\]

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( m \) (integer \( \geq 1 \))
- \( K_1 \) (energy)
- \( n_1 \) (integer \( \geq 0 \))
- \( d_1 \) (degrees)
- \[ \ldots \]
- \( K_m \) (energy)
- \( n_m \) (integer \( \geq 0 \))
- \( d_m \) (degrees)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.
See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

### 23.5.4 Restrictions

This angle style can only be used if LAMMPS was built with the USER_MISC package. See the `Build package` doc page for more info.

### 23.5.5 Related commands

### 23.6 dihedral_style harmonic command

Accelerator Variants: `harmonic/intel`, `harmonic/kk`, `harmonic/omp`

#### 23.6.1 Syntax

```
dihedral_style harmonic
```

#### 23.6.2 Examples

```
dihedral_style harmonic
dihedral_coeff 1 80.0 1 2
```

#### 23.6.3 Description

The `harmonic` dihedral style uses the potential

\[ E = K[1 + d \cos(n\phi)] \]

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy)
- \( d \) (+1 or -1)
- \( n \) (integer \( \geq 0 \))

**Note:** Here are important points to take note of when defining LAMMPS dihedral coefficients for the harmonic style, so that they are compatible with how harmonic dihedrals are defined by other force fields:
- The LAMMPS convention is that the trans position = 180 degrees, while in some force fields trans = 0 degrees.
- Some force fields reverse the sign convention on $d$.
- Some force fields let $n$ be positive or negative which corresponds to $d = 1$ or $d = -1$ for the harmonic style.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

### 23.6.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the `Build package` doc page for more info.

### 23.7 dihedral_style helix command

**Accelerator Variants:** `helix/omp`

#### 23.7.1 Syntax

```
dihedral_style helix
```
23.7.2 Examples

```
dihedral_style helix

dihedral_coeff 1 80.0 100.0 40.0
```

23.7.3 Description

The `helix` dihedral style uses the potential

\[ E = A(1 - \cos(\theta)) + B(1 + \cos(3\theta)) + C(1 + \cos(\theta + \frac{\pi}{4})) \]

This coarse-grain dihedral potential is described in (Guo). For dihedral angles in the helical region, the energy function is represented by a standard potential consisting of three minima, one corresponding to the trans (t) state and the other to gauche states (g+ and g-). The paper describes how the $A$, $B$ and, $C$ parameters are chosen so as to balance secondary (largely driven by local interactions) and tertiary structure (driven by long-range interactions).

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $A$ (energy)
- $B$ (energy)
- $C$ (energy)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Speed packages` doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Speed packages` doc page for more instructions on how to use the accelerated styles effectively.

23.7.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the `Build package` doc page for more info.

23.8 dihedral_style hybrid command

23.8.1 Syntax

```
dihedral_style hybrid style1 style2 ...
```

- style1,style2 = list of one or more dihedral styles

23.8.2 Examples

```
dihedral_style hybrid harmonic helix

dihedral_coeff 1 harmonic 6.0 1 3

dihedral_coeff 2* helix 10 10 10
```

23.8.3 Description

The hybrid style enables the use of multiple dihedral styles in one simulation. An dihedral style is assigned to each dihedral type. For example, dihedrals in a polymer flow (of dihedral type 1) could be computed with a harmonic potential and dihedrals in the wall boundary (of dihedral type 2) could be computed with a helix potential. The assignment of dihedral type to style is made via the dihedral_coeff command or in the data file.

In the dihedral_coeff commands, the name of a dihedral style must be added after the dihedral type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 dihedral_coeff commands set dihedrals of dihedral type 1 to be computed with a harmonic potential with coefficients 6.0, 1, 3 for K, d, n. All other dihedral types (2-N) are computed with a helix potential with coefficients 10, 10, 10 for A, B, C.

If dihedral coefficients are specified in the data file read via the read_data command, then the same rule applies. E.g. “harmonic” or “helix”, must be added after the dihedral type, for each line in the “Dihedral Coeffs” section, e.g.

```
Dihedral Coeffs

1 harmonic 6.0 1 3
2 helix 10 10 10
...
```

If class2 is one of the dihedral hybrid styles, the same rule holds for specifying additional AngleTorsion (and EndBondTorsion, etc) coefficients either via the input script or in the data file. I.e. class2 must be added to each line after the dihedral type. For lines in the AngleTorsion (or EndBondTorsion, etc) section of the data file for dihedral types that are not class2, you must use an dihedral style of skip as a placeholder, e.g.

```
AngleTorsion Coeffs

1 skip
2 class2 1.0 1.0 1.0 3.0 3.0 3.0 30.0 50.0
...
```
Note that it is not necessary to use the dihedral style *skip* in the input script, since AngleTorsion (or EndBondTorsion, etc) coefficients need not be specified at all for dihedral types that are not *class2*.

A dihedral style of *none* with no additional coefficients can be used in place of a dihedral style, either in a input script dihedral_coeff command or in the data file, if you desire to turn off interactions for specific dihedral types.

### 23.8.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

Unlike other dihedral styles, the hybrid dihedral style does not store dihedral coefficient info for individual sub-styles in a *binary restart files*. Thus when restarting a simulation from a restart file, you need to re-specify dihedral_coeff commands.

dihedral_coeff 3 0.000 0.000 0.318 0.000  # HC-CT-CT-HC
```

23.12.3 Description

The opls dihedral style uses the potential

\[
E = \frac{1}{2}K_1[1 + \cos(\phi)] + \frac{1}{2}K_2[1 - \cos(2\phi)] + \\
\frac{1}{2}K_3[1 + \cos(3\phi)] + \frac{1}{2}K_4[1 - \cos(4\phi)]
\]

Note that the usual 1/2 factor is not included in the K values.

This dihedral potential is used in the OPLS force field and is described in (Watkins).

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \(K_1\) (energy)
- \(K_2\) (energy)
- \(K_3\) (energy)
- \(K_4\) (energy)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. ```

23.13.2 Examples

```
dihedral_style  quadratic
  dihedral_coeff  100.0  80.0
```

23.13.3 Description

The quadratic dihedral style uses the potential:

\[ E = K(\phi - \phi_0)^2 \]

This dihedral potential can be used to keep a dihedral in a predefined value (cis=zero, right-hand convention is used). The following coefficients must be defined for each dihedral type via the dihedral_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy)
- \( \phi_0 \) (degrees)

\( \phi_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence \( K \) is effectively energy per radian^2.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages.
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

   dihedral_coeff 1 3 69.3 1 93.9 1 1.90 0 0 1.90 0 &
        49.1 0 0.00 0 1.74 4 1 0.00 0 0 &
        25.2 0 0.00 0 0.00 0 1 48.1 1
```

23.14.3 Description

The spherical dihedral style uses the potential:

\[
\text{energy} = \frac{1}{2} \sum_{ijkl} \left( \cos \theta_{ijkl} - 1 \right)^2
\]
For this dihedral style, the energy can be any function that combines the 4-body dihedral-angle ($\phi$) and the two 3-body bond-angles ($\theta_1$, $\theta_2$). For this reason, there is usually no need to define 3-body “angle” forces separately for the atoms participating in these interactions. It is probably more efficient to incorporate 3-body angle forces into the dihedral interaction even if it requires adding additional terms to the expansion (as was done in the second example). A careful choice of parameters can prevent singularities that occur with traditional force-fields whenever $\theta_1$ or $\theta_2$ approach 0 or 180 degrees.

The last example above corresponds to an interaction with a single energy minima located near $\phi = 93.9$, $\theta_1 = 74.4$, $\theta_2 = 48.1$ degrees, and it remains numerically stable at all angles ($\phi$, $\theta_1$, $\theta_2$). In this example, the coefficients 49.1, and 25.2 can be physically interpreted as the harmonic spring constants for $\theta_1$ and $\theta_2$ around their minima. The coefficient 69.3 is the harmonic spring constant for phi after division by $\sin(74.4)\sin(48.1)$ (the minima positions for $\theta_1$ and $\theta_2$).

The following coefficients must be defined for each dihedral type via the dihedral_coeff command as in the example above, or in the Dihedral Coeffs section of a data file read by the read_data command:

- $n$ (integer $\geq 1$)
- $C_1$ (energy)
- $K_1$ (typically an integer)
- $a_1$ (degrees)
- $u_1$ (typically 0.0 or 1.0)
- $L_1$ (typically an integer)
- $b_1$ (degrees, typically 0.0 or 90.0)
- $v_1$ (typically 0.0 or 1.0)
- $M_1$ (typically an integer)
- $c_1$ (degrees, typically 0.0 or 90.0)
- $w_1$ (typically 0.0 or 1.0)
- [...] 
- $C_n$ (energy)
- $K_n$ (typically an integer)
- $a_n$ (degrees)
- $u_n$ (typically 0.0 or 1.0)
- $L_n$ (typically an integer)
- $b_n$ (degrees, typically 0.0 or 90.0)
• \( v_n \) (typically 0.0 or 1.0)
• \( M_n \) (typically an integer)
• \( c_n \) (degrees, typically 0.0 or 90.0)
• \( w_n \) (typically 0.0 or 1.0)

### 23.14.4 Restrictions

### 23.15 dihedral_style table command

Accelerator Variants: *table/omp*

#### 23.15.1 Syntax

```
dihedral_style table style Ntable
```

• *style* = *linear* or *spline* = method of interpolation
• *Ntable* = size of the internal lookup table

#### 23.15.2 Examples

```
dihedral_style table spline 400
dihedral_style table linear 1000
dihedral_coeff 1 file.table DIH_TABLE1
dihedral_coeff 2 file.table DIH_TABLE2
```
23.15.3 Description

The table dihedral style creates interpolation tables of length \textit{Ntable} from dihedral potential and derivative values listed in a file(s) as a function of the dihedral angle “phi”. The files are read by the \textit{dihedral_coeff} command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and derivative values at each of \textit{Ntable} dihedral angles. During a simulation, these tables are used to interpolate energy and force values on individual atoms as needed. The interpolation is done in one of 2 styles: \textit{linear} or \textit{spline}.

For the \textit{linear} style, the dihedral angle (phi) is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation.

For the \textit{spline} style, cubic spline coefficients are computed and stored at each of the \textit{Ntable} evenly-spaced values in the interpolated table. For a given dihedral angle (phi), the appropriate coefficients are chosen from this list, and a cubic polynomial is used to compute the energy and the derivative at this angle.

The following coefficients must be defined for each dihedral type via the \textit{dihedral_coeff} command as in the example above.

- filename
- keyword

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments). It can begin with one or more comment or blank lines.

```
# Table of the potential and its negative derivative

DIH_TABLE1 (keyword is the first text on line)
N 30 DEGREES (N, NOF, DEGREES, RADIANS, CHECKU/F)
(blank line)
1 -168.0 -1.40351172223 0.0423346818422
2 -156.0 -1.70447981034 0.00811786522531
3 -144.0 -1.62956100432 -0.0184129719987
...
30 180.0 -0.707106781187 0.0719306095245

# Example 2: table of the potential. Forces omitted

DIH_TABLE2
N 30 NOF CHECKU testU.dat CHECKF testF.dat
1 -168.0 -1.40351172223
2 -156.0 -1.70447981034
3 -144.0 -1.62956100432
...
30 180.0 -0.707106781187
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the \textit{dihedral_coeff} command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

Following a blank line, the next \textit{N} lines list the tabulated values. On each line, the first value is the index from 1 to \textit{N}, the second value is the angle value, the third value is the energy (in energy units), and the fourth is \( -dE/d(\phi) \) also in
energy units). The third term is the energy of the 4-atom configuration for the specified angle. The fourth term (when present) is the negative derivative of the energy with respect to the angle (in degrees, or radians depending on whether the user selected DEGREES or RADIANS). Thus the units of the last term are still energy, not force. The dihedral angle values must increase from one line to the next.

Dihedral table splines are cyclic. There is no discontinuity at 180 degrees (or at any other angle). Although in the examples above, the angles range from -180 to 180 degrees, in general, the first angle in the list can have any value (positive, zero, or negative). However the range of angles represented in the table must be strictly less than 360 degrees (2pi radians) to avoid angle overlap. (You may not supply entries in the table for both 180 and -180, for example.) If the user’s table covers only a narrow range of dihedral angles, strange numerical behavior can occur in the large remaining gap.

Parameters:

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the dihedral_style table command. Let Ntable is the number of table entries requested dihedral_style command, and let Nfile be the parameter following “N” in the tabulated file (“30” in the sparse example above). What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at Ntable different points (which are evenly spaced over a 360 degree range, even if the angles in the file are not). The resulting tables of length Ntable are then used as described above, when computing energy and force for individual dihedral angles and their atoms. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile. To insure the nodal points in the user’s file are aligned with the interpolated table entries, the angles in the table should be integer multiples of 360/Ntable degrees, or 2*PI/Ntable radians (depending on your choice of angle units).

The optional “NOF” keyword allows the user to omit the forces (negative energy derivatives) from the table file (normally located in the fourth column). In their place, forces will be calculated automatically by differentiating the potential energy function indicated by the third column of the table (using either linear or spline interpolation).

The optional “DEGREES” keyword allows the user to specify angles in degrees instead of radians (default).

The optional “RADIANS” keyword allows the user to specify angles in radians instead of degrees. (Note: This changes the way the forces are scaled in the fourth column of the data file.)

The optional “CHECKU” keyword is followed by a filename. This allows the user to save all of the Ntable different entries in the interpolated energy table to a file to make sure that the interpolated function agrees with the user’s expectations. (Note: You can temporarily increase the Ntable parameter to a high value for this purpose. “Ntable” is explained above.)

The optional “CHECKF” keyword is analogous to the “CHECKU” keyword. It is followed by a filename, and it allows the user to check the interpolated force table. This option is available even if the user selected the “NOF” option.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.
23.15.4 Restart, fix_modify, output, run start/stop, minimize info

This dihedral style writes the settings for the “dihedral_style table” command to binary restart files, so a dihedral_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, dihedral_coeff commands do need to be specified in the restart input script.

23.15.5 Restrictions

This dihedral style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

23.15.6 Related commands

dihedral_coeff

23.16 dihedral_style table/cut command

23.16.1 Syntax

```
dihedral_style table/cut style Ntable
```

- style = linear or spline = method of interpolation
- Ntable = size of the internal lookup table

23.16.2 Examples

```
dihedral_style table/cut spline 400
dihedral_style table/cut linear 1000
dihedral_coeff 1 aat 1.0 177 180 file.table DIH_TABLE1
```

23.16.3 Description

The table/cut dihedral style creates interpolation tables of length Ntable from dihedral potential and derivative values listed in a file(s) as a function of the dihedral angle “phi”. In addition, an analytic cutoff that is quadratic in the bond-angle (theta) is applied in order to regularize the dihedral interaction. The dihedral table files are read by the dihedral_coeff command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and derivative values at each of Ntable dihedral angles. During a simulation, these tables are used to interpolate energy and force values on individual atoms as needed. The interpolation is done in one of 2 styles: linear or spline.
For the *linear* style, the dihedral angle (phi) is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation.

For the *spline* style, cubic spline coefficients are computed and stored at each of the *Ntable* evenly-spaced values in the interpolated table. For a given dihedral angle (phi), the appropriate coefficients are chosen from this list, and a cubic polynomial is used to compute the energy and the derivative at this angle.

The following coefficients must be defined for each dihedral type via the *dihedral_coeff* command as in the example above.

- style (aat)
- cutoff prefactor
- cutoff angle1
- cutoff angle2
- filename
- keyword

The cutoff dihedral style uses a tabulated dihedral interaction with a cutoff function:

\[
    f(\theta) = K \quad \theta < \theta_1 \\
    f(\theta) = K \left(1 - \frac{(\theta - \theta_1)^2}{(\theta_2 - \theta_1)^2}\right) \quad \theta_1 < \theta < \theta_2
\]

The cutoff specifies an prefactor to the cutoff function. While this value would ordinarily equal 1 there may be situations where the value should change.

The cutoff \(\theta_1\) specifies the angle (in degrees) below which the dihedral interaction is unmodified, i.e. the cutoff function is 1.

The cutoff function is applied between \(\theta_1\) and \(\theta_2\), which is the angle at which the cutoff function drops to zero. The value of zero effectively “turns off” the dihedral interaction.

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments). It can begin with one or more comment or blank lines.

```
# Table of the potential and its negative derivative

DIH_TABLE1  (keyword is the first text on line)

```

(continues on next page)
A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the `dihedral_coeff` command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the angle value, the third value is the energy (in energy units), and the fourth is \(-dE/d(\phi)\) also in energy units. The third term is the energy of the 4-atom configuration for the specified angle. The fourth term (when present) is the negative derivative of the energy with respect to the angle (in degrees, or radians depending on whether the user selected DEGREES or RADIANS). Thus the units of the last term are still energy, not force. The dihedral angle values must increase from one line to the next.

Dihedral table splines are cyclic. There is no discontinuity at 180 degrees (or at any other angle). Although in the examples above, the angles range from -180 to 180 degrees, in general, the first angle in the list can have any value (positive, zero, or negative). However the range of angles represented in the table must be strictly less than 360 degrees (2π radians) to avoid angle overlap. (You may not supply entries in the table for both 180 and -180, for example.) If the user’s table covers only a narrow range of dihedral angles, strange numerical behavior can occur in the large remaining gap.

**Parameters:**

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the `dihedral_style table` command. Let Ntable be the number of table entries requested dihedral_style command, and let Nfile be the parameter following “N” in the tabulated file (“30” in the sparse example above). What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at Ntable different points (which are evenly spaced over a 360 degree range, even if the angles in the file are not). The resulting tables of length Ntable are then used as described above, when computing energy and force for individual dihedral angles and their atoms. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile. To insure the nodal points in the user’s file are aligned with the interpolated table entries, the angles in the table should be integer multiples of 360/Ntable degrees, or 2*PI/Ntable radians (depending on your choice of angle units).

The optional “NOF” keyword allows the user to omit the forces (negative energy derivatives) from the table file (normally located in the fourth column). In their place, forces will be calculated automatically by differentiating the potential energy function indicated by the third column of the table (using either linear or spline interpolation).

The optional “DEGREES” keyword allows the user to specify angles in degrees instead of radians (default).

The optional “RADIANS” keyword allows the user to specify angles in radians instead of degrees. (Note: This changes the way the forces are scaled in the fourth column of the data file.)

The optional “CHECKU” keyword is followed by a filename. This allows the user to save all of the Ntable different entries in the interpolated energy table to a file to make sure that the interpolated function agrees with the user’s expectations. (Note: You can temporarily increase the Ntable parameter to a high value for this purpose. “Ntable” is explained above.)

The optional “CHECKF” keyword is analogous to the “CHECKU” keyword. It is followed by a filename, and it allows the user to check the interpolated force table. This option is available even if the user selected the “NOF” option.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.
23.16.4 Restart, fix_modify, output, run start/stop, minimize info

This dihedral style writes the settings for the “dihedral_style table/cut” command to binary restart files, so a dihedral_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, dihedral_coeff commands do need to be specified in the restart input script.

23.16.5 Restrictions

This dihedral style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

23.16.6 Related commands

dihedral_coeff, dihedral_style table

23.16.7 Default

none

23.17 dihedral_style zero command

23.17.1 Syntax

```
dihedral_style zero [nocoeff]
```

23.17.2 Examples

```
dihedral_style zero
dihedral_style zero nocoeff
dihedral_coeff *
```

23.17.3 Description

Using a dihedral style of zero means dihedral forces and energies are not computed, but the geometry of dihedral quadruplets is still accessible to other commands.

As an example, the compute dihedral/local command can be used to compute the theta values for the list of quadruplets of dihedral atoms listed in the data file read by the read_data command. If no dihedral style is defined, this command cannot be used.

The optional nocoeff flag allows to read data files with a DihedralCoeff section for any dihedral style. Similarly, any dihedral_coeff commands will only be checked for the dihedral type number and the rest ignored.

Note that the dihedral_coeff command must be used for all dihedral types, though no additional values are specified.

24.1 improper_style class2 command

Accelerator Variants: class2/omp, class2/kk

24.1.1 Syntax

improper_style class2

24.1.2 Examples

improper_style class2
improper_coeff 1 100.0 0
improper_coeff * aa 0.0 0.0 0.0 115.06 130.01 115.06

24.1.3 Description

The class2 improper style uses the potential

\[ E = E_i + E_{aa} \]
\[ E_i = K \left( \chi_{ijkl} + \chi_{kjli} + \chi_{ljik} \right) / 3 - \chi_0^2 \]
\[ E_{aa} = M_1 (\theta_{ijk} - \theta_1) (\theta_{kjl} - \theta_3) + \]
\[ M_2 (\theta_{ijk} - \theta_1) (\theta_{ijl} - \theta_2) + \]
\[ M_3 (\theta_{ijl} - \theta_2) (\theta_{kjl} - \theta_3) \]

where \( E_i \) is the improper term and \( E_{aa} \) is an angle-angle term. The 3 \( \chi \) terms in \( E_i \) are an average over 3 out-of-plane angles.

The 4 atoms in an improper quadruplet (listed in the data file read by the read_data command) are ordered I,J,K,L. \( \chi_{ijkl} \) refers to the angle between the plane of I,J,K and the plane of J,K,L, and the bond JK lies in both planes. Similarly for \( \chi_{kjli} \) and \( \chi_{ljik} \). Note that atom J appears in the common bonds (JI, JK, JL) of all 3 \( \chi \) terms. Thus J (the second atom in the quadruplet) is the atom of symmetry in the 3 \( \chi \) angles.

The subscripts on the various \( \theta \)s refer to different combinations of 3 atoms (I,J,K,L) used to form a particular angle. E.g. \( \theta_{ijl} \) is the angle formed by atoms I,J,L with J in the middle. \( \theta_1, \theta_2, \theta_3 \) are the equilibrium positions of those angles. Again, atom J (the second atom in the quadruplet) is the atom of symmetry in the theta angles, since it is always the center atom.
Since atom J is the atom of symmetry, normally the bonds J-I, J-K, J-L would exist for an improper to be defined between the 4 atoms, but this is not required.

See (Sun) for a description of the COMPASS class2 force field.

Coefficients for the $E_i$ and $E_{aa}$ formulas must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands.

These are the 2 coefficients for the $E_i$ formula:

- $K$ (energy)
- $\chi_0$ (degrees)

$\chi_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence $K$ is effectively energy per radian$^2$.

For the $E_{aa}$ formula, each line in a `improper_coeff` command in the input script lists 7 coefficients, the first of which is $aa$ to indicate they are AngleAngle coefficients. In a data file, these coefficients should be listed under a `AngleAngle Coeffs` heading and you must leave out the $aa$, i.e. only list 6 coefficients after the improper type.

- $aa$
- $M_1$ (energy)
- $M_2$ (energy)
- $M_3$ (energy)
- $\theta_1$ (degrees)
- $\theta_2$ (degrees)
- $\theta_3$ (degrees)

The $\theta$ values are specified in degrees, but LAMMPS converts them to radians internally; hence the various $M$ are effectively energy per radian$^2$.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 24.1.4 Restrictions

This improper style can only be used if LAMMPS was built with the CLASS2 package. See the Build package doc page for more info.
24.1.5 Related commands

improper_coeff

24.1.6 Default

none

24.2 improper_style cossq command

Accelerator Variants: cossq/omp

24.2.1 Syntax

improper_style cossq

24.2.2 Examples

improper_style cossq
improper_coeff 1 4.0 0.0

24.2.3 Description

The cossq improper style uses the potential

\[ E = \frac{1}{2} K \cos^2 (\chi - \chi_0) \]

where \( \chi \) is the improper angle, \( \chi_0 \) is its equilibrium value, and \( K \) is a prefactor.

If the 4 atoms in an improper quadruplet (listed in the data file read by the read_data command) are ordered I,J,K,L then \( \chi \) is the angle between the plane of I,J,K and the plane of J,K,L. Alternatively, you can think of atoms J,K,L as being in a plane, and atom I above the plane, and \( \chi \) as a measure of how far out-of-plane I is with respect to the other 3 atoms.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy)
- \( \chi_0 \) (degrees)
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

### 24.3 improper_style cvff command

Accelerator Variants: `cvff/intel`, `cvff/omp`

#### 24.3.1 Syntax

```
improper_style cvff
```

#### 24.3.2 Examples

```
improper_style cvff
improper_coeff 1 80.0 -1 4
```
24.3.3 Description

The cvff improper style uses the potential

\[ E = K \left[ 1 + d \cos(n\phi) \right] \]

where phi is the improper dihedral angle.

If the 4 atoms in an improper quadruplet (listed in the data file read by the read_data command) are ordered I,J,K,L then the improper dihedral angle is between the plane of I,J,K and the plane of J,K,L. Note that because this is effectively a dihedral angle, the formula for this improper style is the same as for dihedral_style harmonic.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- K (energy)
- d (+1 or -1)
- n (0,1,2,3,4,6)

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

24.3.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

24.4 improper_style distance command

24.4.1 Syntax

```
improper_style distance
```

24.4.2 Examples

```
improper_style distance
improper_coeff i 80.0 100.0
```

24.4.3 Description

The `distance` improper style uses the potential

\[ E = K_2d^2 + K_4d^4 \]

where \( d \) is the distance between the central atom and the plane formed by the other three atoms. If the 4 atoms in an improper quadruplet (listed in the data file read by the `read_data` command) are ordered I,J,K,L then the I-atom is assumed to be the central atom.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.
The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K_2 \) (energy/distance^2)
- \( K_4 \) (energy/distance^4)

### 24.4.4 Restrictions

This improper style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

### 24.4.5 Related commands

improper_style distharm
```

#### 24.5.2 Examples

```bash
improper_style distharm
improper_coeff 1 25.0 0.5
```

#### 24.5.3 Description

The *dinharm* improper style uses the potential

\[
E = K(d - d_0)^2
\]

where \( d \) is the oriented distance between the central atom and the plane formed by the other three atoms. If the 4 atoms in an improper quadruplet (listed in the data file read by the read_data command) are ordered I,J,K,L then the L-atom is assumed to be the central atom. Note that this is different from the convention used in the improper_style distance. The distance \( d \) is oriented and can take on negative values. This may lead to unwanted behavior if \( d_0 \) is not equal to zero.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy/distance^2)
• \( d_0 \) (distance)

## 24.5.4 Restrictions

This improper style can only be used if LAMMPS was built with the USER-YAFF package. See the *Build package* doc page for more info.

## 24.5.5 Related commands

### 24.6 improper_style fourier command

Accelerator Variants: *fourier/omp*

#### 24.6.1 Syntax

```
improper_style fourier
```

#### 24.6.2 Examples

```
improper_style fourier
improper_coeff 1 100.0 0.0 1.0 0.5 1
```

#### 24.6.3 Description

The *fourier* improper style uses the following potential:

\[
E = K[C_0 + C_1 \cos(\omega) + C_2 \cos(2\omega)]
\]

where \( K \) is the force constant, \( C_0, C_1, C_2 \) are dimensionless coefficients, and \( \omega \) is the angle between the IL axis and the IJK plane:
If all parameter (see below) is not zero, the all the three possible angles will taken in account.

The following coefficients must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $K$ (energy)
- $C_0$ (unitless)
- $C_1$ (unitless)
- $C_2$ (unitless)
- all (0 or 1, optional)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

24.7 improper_style harmonic command

Accelerator Variants: harmonic/intel, harmonic/kk, harmonic/omp

24.7.1 Syntax

improper_style harmonic

24.7.2 Examples

improper_style harmonic
improper_coeff 1 100.0 0

24.7.3 Description

The harmonic improper style uses the potential

\[ E = K(\chi - \chi_0)^2 \]

where \( \chi \) is the improper angle, \( \chi_0 \) is its equilibrium value, and \( K \) is a prefactor. Note that the usual 1/2 factor is included in \( K \).

If the 4 atoms in an improper quadruplet (listed in the data file read by the read_data command) are ordered IJ,K,L then \( \chi \) is the angle between the plane of IJ,K and the plane of J,K,L. Alternatively, you can think of atoms J,K,L as being in a plane, and atom I above the plane, and \( \chi \) as a measure of how far out-of-plane I is with respect to the other 3 atoms.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy)
• $\chi_0$ (degrees)

$\chi_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence $K$ is effectively energy per radian$^2$.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. ### 24.7.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

### 24.7.5 Related commands

`improper_coeff`

### 24.7.6 Default

none

### 24.8 improper_style hybrid command

#### 24.8.1 Syntax

```
improper_style hybrid style1 style2 ...
```

• style1,style2 = list of one or more improper styles

#### 24.8.2 Examples

```
improper_style hybrid harmonic helix
improper_coeff 1 harmonic 120.0 30
improper_coeff 2 cvff 20.0 -1 2
```
24.8.3 Description

The *hybrid* style enables the use of multiple improper styles in one simulation. An improper style is assigned to each improper type. For example, improvers in a polymer flow (of improper type 1) could be computed with a *harmonic* potential and impropers in the wall boundary (of improper type 2) could be computed with a *cvff* potential. The assignment of improper type to style is made via the `improper_coeff` command or in the data file.

In the `improper_coeff` command, the first coefficient sets the improper style and the remaining coefficients are those appropriate to that style. In the example above, the 2 `improper_coeff` commands would set impropers of improper type 1 to be computed with a *harmonic* potential with coefficients 120.0, 30 for $K$, $\chi_0$. Improper type 2 would be computed with a *cvff* potential with coefficients 20.0, -1, 2 for $K$, $d$, and $n$, respectively.

If the improper *class2* potential is one of the hybrid styles, it requires additional AngleAngle coefficients be specified in the data file. These lines must also have an additional “class2” argument added after the improper type. For improper types which are assigned to other hybrid styles, use the style name (e.g. “harmonic”) appropriate to that style. The AngleAngle coeffs for that improper type will then be ignored.

An improper style of *none* can be specified as the second argument to the `improper_coeff` command, if you desire to turn off certain improper types.

24.8.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

Unlike other improper styles, the hybrid improper style does not store improper coefficient info for individual sub-styles in a *binary restart files*. Thus when restarting a simulation from a restart file, you need to re-specify improper_coeff commands.

24.8.5 Related commands

`improper_coeff`

24.8.6 Default

24.9 improper_style inversion/harmonic command

24.9.1 Syntax

```
improper_style inversion/harmonic
```
24.9.2 Examples

```plaintext
improper_style inversion/harmonic
improper_coeff 1 18.776340 0.000000
```

24.9.3 Description

The *inversion/harmonic* improper style follows the Wilson-Decius out-of-plane angle definition and uses an harmonic potential:

\[ E = K (\omega - \omega_0)^2 \]

where \( K \) is the force constant and \( \omega \) is the angle evaluated for all three axis-plane combinations centered around the atom I. For the IL axis and the IJK plane \( \omega \) looks as follows:

![Diagram](image)

Note that the *inversion/harmonic* angle term evaluation differs to the *improper_umbrella* due to the cyclic evaluation of all possible angles \( \omega \).

The following coefficients must be defined for each improper type via the *improper_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( K \) (energy)
- \( \omega_0 \) (degrees)

If \( \omega_0 = 0 \) the potential term has a single minimum for the planar structure. Otherwise it has two minima at +/- \( \omega_0 \), with a barrier in between.
24.9.4 Restrictions

This improper style can only be used if LAMMPS was built with the USER-MOFFF package. See the Build package doc page for more info.

24.11.1 Syntax

\texttt{improper_style ring}

24.11.2 Examples

\texttt{improper_style ring}
\texttt{improper_coeff 1 8000 70.5}

24.11.3 Description

The \textit{ring} improper style uses the potential

\[ E = \frac{1}{6} K (\Delta_{ijl} + \Delta_{ijk} + \Delta_{kjl})^6 \]

\[ \Delta_{ijl} = \cos \theta_{ijl} - \cos \theta_0 \]

\[ \Delta_{ijk} = \cos \theta_{ijk} - \cos \theta_0 \]

\[ \Delta_{kjl} = \cos \theta_{kjl} - \cos \theta_0 \]

where \( K \) is a prefactor, \( \theta \) is the angle formed by the atoms specified by (i,j,k,l) indices and \( \theta_0 \) its equilibrium value.

If the 4 atoms in an improper quadruplet (listed in the data file read by the \texttt{read_data} command) are ordered i,j,k,l then \( \theta_{ijl} \) is the angle between atoms i,j and l, \( \theta_{ijk} \) is the angle between atoms i,j and k, \( \theta_{kjl} \) is the angle between atoms j,k, and l.

The “ring” improper style implements the improper potential introduced by Destree et al., in Equation (9) of \textit{(Destree)}. This potential does not affect small amplitude vibrations but is used in an ad-hoc way to prevent the onset of accidentally large amplitude fluctuations leading to the occurrence of a planar conformation of the three bonds i-j, j-k and j-l, an intermediate conformation toward the chiral inversion of a methine carbon. In the “Improper” section of data file four atoms: i, j, k and l are specified with i,j and l lying on the backbone of the chain and k specifying the chirality of j.

The following coefficients must be defined for each improper type via the \texttt{improper_coeff} command as in the example above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands:

- \( K \) (energy)
- \( \theta_0 \) (degrees)

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Speed packages}
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 24.11.4 Restrictions

This improper style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

### 24.11.5 Related commands

improper_coeff

### 24.12 improper_style sqdistharm command

#### 24.12.1 Syntax

```
improper_style sqdistharm
```

#### 24.12.2 Examples

```
improper_style sqdistharm
improper_coeff 1 50.0 0.1
```

#### 24.12.3 Description

The sqdistharm improper style uses the potential

\[ E = K(d^2 - d_0^2)^2 \]

where \( d \) is the distance between the central atom and the plane formed by the other three atoms. If the 4 atoms in an improper quadruplet (listed in the data file read by the read_data command) are ordered I,J,K,L then the L-atom is assumed to be the central atom. Note that this is different from the convention used in the improper_style distance.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy/distance^4)
- \( d_0^2 \) (distance^2)
Note that $d_0^2$ (in units distance^2) has be provided and not $d_0$.

### 24.12.4 Restrictions

This improper style can only be used if LAMMPS was built with the USER-MISC package. See the Build package doc page for more info.

### 24.12.5 Related commands

*improper_coeff*

### 24.12.6 Default

### 24.13 improper_style umbrella command

Accelerator Variants: *umbrella/omp*

#### 24.13.1 Syntax

```
improper_style umbrella
```

#### 24.13.2 Examples

```
improper_style umbrella
improper_coeff 1 100.0 180.0
```

#### 24.13.3 Description

The *umbrella* improper style uses the following potential, which is commonly referred to as a classic inversion and used in the DREIDING force field:

\[
E = \frac{1}{2} K \left( \frac{1}{\sin \omega_0} \right)^2 (\cos \omega - \cos \omega_0)^2 \quad \omega_0 \neq 0^\circ
\]

\[
E = K (1 - \cos \omega) \quad \omega_0 = 0^\circ
\]

where $K$ is the force constant and $\omega$ is the angle between the IL axis and the IJK plane:
If $\omega_0 = 0$ the potential term has a minimum for the planar structure. Otherwise it has two minima at $\omega + / - \omega_0$, with a barrier in between.

See (Mayo) for a description of the DREIDING force field.

The following coefficients must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $K$ (energy)
- $\omega_0$ (degrees)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Speed packages doc page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, USER-INTEL, KOKKOS, USER-OMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Speed packages doc page for more instructions on how to use the accelerated styles effectively.

### 24.13.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.
24.13.5 Related commands

*improper_coeff*

24.13.6 Default

*none*

24.14 improper_style zero command

24.14.1 Syntax

```improper_style zero [nocoeff]```

24.14.2 Examples

```improper_style  zero
improper_style  zero nocoeff
improper_coeff *
```

24.14.3 Description

Using an improper style of zero means improper forces and energies are not computed, but the geometry of improper quadruplets is still accessible to other commands.

As an example, the *compute improper/local* command can be used to compute the chi values for the list of quadruplets of improper atoms listed in the data file read by the *read_data* command. If no improper style is defined, this command cannot be used.

The optional *nocoeff* flag allows to read data files with a ImproperCoeff section for any improper style. Similarly, any improper_coeff commands will only be checked for the improper type number and the rest ignored.

Note that the *improper_coeff* command must be used for all improper types, though no additional values are specified.
